ELSEVIER

CONTENTS

SECTION 1
Concepts in Nursing Practice

1 Professional Nursing Practice, 2
2 Health Disparities and Culturally Competent Care, 19
3 Health History and Physical Examination, 36
4 Patient and Caregiver Teaching, 47
5 Chronic Illness and Older Adults, 61
6 Complementary and Alternative Therapies, 79
7 Stress and Stress Management, 88
8 Sleep and Sleep Disorders, 99
9 Pain, 114
10 Palliative Care at End of Life, 140
11 Substance Abuse, 154

SECTION 2
Pathophysiologic Mechanisms of Disease

12 Inflammation and Wound Healing, 172
13 Genetics and Genomics, 190
14 Altered Immune Responses and Transplantation, 203
15 Infection and Human Immunodeficiency Virus Infection, 226
16 Cancer, 247
17 Fluid, Electrolyte, and Acid-Base Imbalances, 285

SECTION 3
Perioperative Care

18 *Nursing Management* Preoperative Care, 317
19 *Nursing Management* Intraoperative Care, 333
20 *Nursing Management* Postoperative Care, 349

SECTION 4
Problems Related to Altered Sensory Input

21 *Nursing Assessment* Visual and Auditory Systems, 368
22 *Nursing Management* Visual and Auditory Problems, 386
23 *Nursing Assessment* Integumentary System, 414
24 *Nursing Management* Integumentary Problems, 427
25 *Nursing Management* Burns, 450

SECTION 5
Problems of Oxygenation: Ventilation

26 *Nursing Assessment* Respiratory System, 475
27 *Nursing Management* Upper Respiratory Problems, 497
28 *Nursing Management* Lower Respiratory Problems, 521
29 *Nursing Management* Obstructive Pulmonary Diseases, 560

SECTION 6
Problems of Oxygenation: Transport

30 *Nursing Assessment* Hematologic System, 613
31 *Nursing Management* Hematologic Problems, 632

SECTION 7
Problems of Oxygenation: Perfusion

32 *Nursing Assessment* Cardiovascular System, 686
33 *Nursing Management* Hypertension, 709
34 *Nursing Management* Coronary Artery Disease and Acute Coronary Syndrome, 730
35 *Nursing Management* Heart Failure, 766
36 *Nursing Management* Dysrhythmias, 787
37 *Nursing Management* Inflammatory and Structural Heart Disorders, 810
38 *Nursing Management* Vascular Disorders, 833

SECTION 8
Problems of Ingestion, Digestion, Absorption, and Elimination

39 *Nursing Assessment*
Gastrointestinal System, 865
40 *Nursing Management*
Nutritional Problems, 886
41 *Nursing Management*
Obesity, 906
42 *Nursing Management*
Upper Gastrointestinal Problems, 924
43 *Nursing Management*
Lower Gastrointestinal Problems, 961
44 *Nursing Management*
Liver, Pancreas, and Biliary Tract Problems, 1006

SECTION 9
Problems of Urinary Function

45 *Nursing Assessment*
Urinary System, 1046
46 *Nursing Management*
Renal and Urologic Problems, 1064
47 *Nursing Management*
Acute Kidney Injury and Chronic Kidney Disease, 1101

SECTION 10
Problems Related to Regulatory and Reproductive Mechanisms

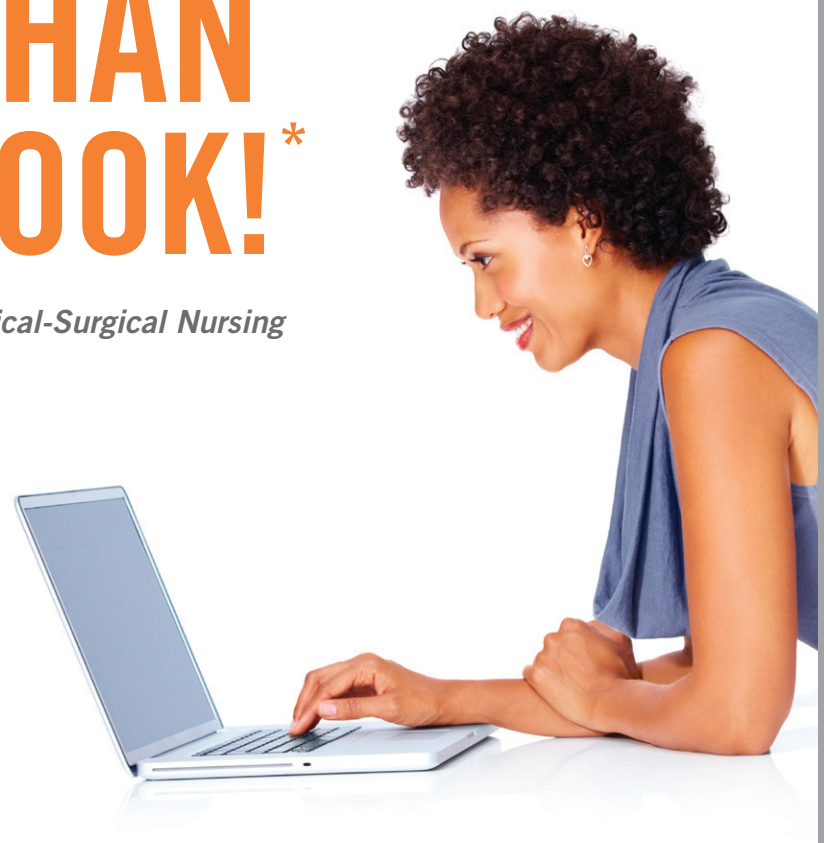
48 *Nursing Assessment*
Endocrine System, 1134
49 *Nursing Management*
Diabetes Mellitus, 1153
50 *Nursing Management*
Endocrine Problems, 1189
51 *Nursing Assessment*
Reproductive System, 1218
52 *Nursing Management*
Breast Disorders, 1238
53 *Nursing Management*
Sexually Transmitted Infections, 1261
54 *Nursing Management*
Female Reproductive Problems, 1276
55 *Nursing Management*
Male Reproductive Problems, 1307

SECTION 11
Problems Related to Movement and Coordination

56 *Nursing Assessment*
Nervous System, 1335
57 *Nursing Management*
Acute Intracranial Problems, 1356
58 *Nursing Management*
Stroke, 1388
59 *Nursing Management*
Chronic Neurologic Problems, 1413
60 *Nursing Management*
Alzheimer's Disease, Dementia, and Delirium, 1443
61 *Nursing Management*
Peripheral Nerve and Spinal Cord Problems, 1463
62 *Nursing Assessment*
Musculoskeletal System, 1489
63 *Nursing Management*
Musculoskeletal Trauma and Orthopedic Surgery, 1505
64 *Nursing Management*
Musculoskeletal Problems, 1539
65 *Nursing Management*
Arthritis and Connective Tissue Diseases, 1561

SECTION 12
Nursing Care in Critical Care Settings

66 *Nursing Management*
Critical Care, 1598
67 *Nursing Management*
Shock, Systemic Inflammatory Response Syndrome, and Multiple Organ Dysfunction Syndrome, 1631
68 *Nursing Management*
Respiratory Failure and Acute Respiratory Distress Syndrome, 1654
69 *Nursing Management*
Emergency, Terrorism, and Disaster Nursing, 1674



APPENDIXES

A Basic Life Support for Health Care Providers, 1696
B Nursing Diagnoses, 1699
C Laboratory Reference Intervals, 1701

Glossary, G-1
Illustration Credits, IC-1
Index, I-1

ELSEVIER evolve

YOU'VE JUST PURCHASED MORE THAN A TEXTBOOK!*

Evolve Student Resources for *Medical-Surgical Nursing* include the following:

- NCLEX® Review Questions
- Key Points
- Pre-Tests
- Answer Guidelines for Case Studies
- Rationales for Bridge to NCLEX® Examination questions
- Case Studies
- Customizable Nursing Care Plans
- Concept Map Creator
- Concept Maps for Case Studies
- Glossary
- Stress-Busting Kit for Nursing Students
- Animations, Videos, and Audio
- Fluids and Electrolytes Tutorial
- Content Updates
- Supplemental eFigures and eTables

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

ABOUT THE AUTHORS

SHARON L. LEWIS, RN, PhD, FAAN

Sharon Lewis received her Bachelor of Science in nursing from the University of Wisconsin–Madison, Master of Science in nursing with a minor in biological sciences from the University of Colorado–Denver, and PhD in immunology from the Department of Pathology at the University of New Mexico School of Medicine. She had a 2-year postdoctoral fellowship from the National Kidney Foundation. Her more than 40 years of teaching experience include inservice education and teaching in associate degree, baccalaureate, master's degree, and doctoral programs in Maryland, Illinois, Wisconsin, New Mexico, and Texas. Favorite teaching areas are pathophysiology, immunology, and family caregiving. She has been actively involved in clinical research for the past 30 years, investigating altered immune responses in various disorders and developing a stress management program for family caregivers. Her primary professional responsibility is disseminating the Stress-Busting for Family Caregivers Program that she developed. Her free time is spent biking, landscaping, gardening, and being a grandmother.

SHANNON RUFF DIRKSEN, RN, PhD, FAAN

Shannon Dirksen is Associate Professor at the College of Nursing and Health Innovation, Arizona State University. She received her Bachelor of Science in nursing from Arizona State University, Master of Science in nursing from the University of Arizona, and doctorate in clinical nursing research with a minor in psychology from the University of Arizona. She has over 25 years of undergraduate and graduate teaching experience at the University of Arizona, Edith Cowan University (Western Australia), Intercollegiate College of Nursing–Washington State University, and University of New Mexico. She has been on the faculty at Arizona State University since 1996. She currently teaches nursing theory and research, including evidence-based practice. Her research for the past 25 years has focused on quality of life among individuals diagnosed with cancer. Her free time is spent traveling, gardening, bicycling, and reading.

MARGARET McLEAN HEITKEMPER, RN, PhD, FAAN

Margaret Heitkemper is Professor and Chairperson, Department of Biobehavioral Nursing and Health Systems at the School of Nursing, and Adjunct Professor, Division of Gastroenterology at the School of Medicine at the University of Washington. She is also Director of the National Institutes of Health-National Institute for Nursing Research–funded Center for Research on Management of Sleep Disturbances at the University of Washington. In the fall of 2006, Dr. Heitkemper was appointed the Elizabeth Sterling Soule Endowed Chair in Nursing. Dr. Heitkemper received her Bachelor of Science in nursing from Seattle University, a Master of Nursing in gerontologic nursing from the University of Washington, and a doctorate in Physiology and Biophysics from the University of Illinois–Chicago. She has been on faculty at the University of Washington since 1981 and has been the recipient of three School of Nursing Excellence in Teaching awards and the University of Washington Distinguished Teaching Award. In addition, in 2002 she received the Distinguished Nutrition Support Nurse Award from the American Society for Parenteral and Enteral Nutrition (ASPEN), in 2003 the American Gastroenterological Association and Janssen Award for Clinical Research in Gastroenterology, and in 2005 she was the first recipient of the Pfizer and Friends of the National Institutes for Nursing Research Award for Research in Women's Health.

LINDA BUCHER, RN, PhD, CEN, CNE

Linda Bucher is an Emerita Professor in the School of Nursing at the University of Delaware in Newark, Delaware. She also is a consultant/mentor in the W. Cary Edwards School of Nursing at Thomas Edison State College. She received her Bachelor of Science in nursing from Thomas Jefferson University in Philadelphia, her Master of Science in adult health and illness from the University of Pennsylvania in Philadelphia, and her doctorate in nursing from Widener University in Chester, Pennsylvania. Her 37 years of nursing experience has spanned staff and patient education, acute and critical care nursing, and teaching in associate, baccalaureate, and graduate nursing programs in New Jersey, Pennsylvania, and Delaware. Her preferred teaching areas include emergency and cardiac nursing and evidence-based practice. She maintains her clinical practice by working as an emergency nurse, is an active member of the American Association of Critical Care Nurses, and enjoys working as a volunteer nurse for Operation Smile. In her free time she enjoys traveling and skiing with her family.

CONTRIBUTORS

Richard Arbour, RN, MSN, CCRN, CNRN, CCNS, FAAN
Critical Care Clinical Nurse Specialist
Albert Einstein Healthcare Network
Philadelphia, Pennsylvania

Margaret Baker, RN, PhD, CNL
Associate Professor
University of Washington School of Nursing
Seattle, Washington

Elisabeth G. Bradley, RN, MS, ACNS-BC
Clinical Leader Cardiovascular Prevention Program
Christiana Care Health System
Newark, Delaware

Lucy Bradley-Springer, RN, PhD, ACRN, FAAN
Associate Professor
University of Colorado–Denver, Anschutz Medical Campus
Denver, Colorado

Jormain Cady, DNP, ARNP, AOCN
Nurse Practitioner
Virginia Mason Medical Center
Department of Radiation Oncology
Seattle, Washington

Paula Cox-North, RN, PhD, NP-C
Harborview Medical Center
Seattle, Washington

Anne Croghan, MN, ARNP
Nurse Practitioner
Seattle Gastroenterology Associates
Seattle, Washington

Betty Jean Reid Czarapata, MSN, ANP-BC, CUNP
Nurse Practitioner
Urology Wellness Center
Gaithersburg, Maryland

Judi Daniels, PhD, FNP, PNP
Advanced Practice Registered Nurse
Kentucky Polk-Dalton Clinic
Lexington, Kentucky;
Course Coordinator
Frontier Nursing University
Richmond, Kentucky

Rose DiMaria-Ghalili, RN, PhD, CNSC
Associate Professor of Nursing
College of Nursing and Health Professions
Drexel University
Philadelphia, Pennsylvania

Angela DiSabatino, RN, MS
Manager, Cardiovascular Clinical Trials
Christiana Care Health System
Newark, Delaware

Laura Dulski, MSN, RNC-HROB, CNE
Assistant Professor
Resurrection University
Chicago, Illinois

Susan J. Eisel, RN, MSEd
Associate Professor of Nursing
Mercy College of Ohio
Toledo, Ohio

Deborah Hamolsky, RN, MS, AOCNS
Clinical Nurse IV
Carol Franc Buck Breast Care Center
UCSF Helen Diller Family Comprehensive Cancer Center
San Francisco, California

Mariann M. Harding, RN, PhD, CNE
Associate Professor of Nursing
Kent State University at Tuscarawas
New Philadelphia, Ohio

Jerry Harvey, RN, MS, BC
Assistant Professor of Nursing
Liberty University
Lynchburg, Virginia

Carol Headley, RN, DNSc, ACNP-BC, CNN
Nephrology Nurse Practitioner
Veterans Affairs Medical Center
Memphis, Tennessee

Teresa E. Hills, RN, MSN, ACNP-BC, CNRN
Neurosurgery Critical Care Nurse Practitioner
Christiana Care Health System
Newark, Delaware

Christine Hoch, RN, MSN
Nursing Instructor
Delaware Technical Community College
Newark, Delaware

David M. Horner, CRNA, MS, APN
Nurse Anesthetist
Virtua Hospital
Marlton, New Jersey

Joyce Jackowski, MS, FNP-BC, AOCNP
Nurse Practitioner
Virginia Cancer Specialists
Arlington, Virginia

Kay Jarrell, RN, MS, CNE
Clinical Associate Professor
College of Nursing and Health Innovation
Arizona State University
Phoenix, Arizona

Sharmila Johnson, MSN, ACNS-BC, CCRN
Cardiovascular Clinical Nurse Specialist
Christiana Care Health System
Newark, Delaware

Jane Steinman Kaufman, RN, MS, ANP-BC, CRNP
Advanced Senior Lecturer
University of Pennsylvania School of Nursing
Philadelphia, Pennsylvania

Katherine A. Kelly, RN, DNP, FNP-C, CEN
Assistant Professor
School of Nursing
California State University
Sacramento, California

Lindsay L. Kindler, RN, PhD, CNS
Research Associate
Kaiser Permanente Center for Health Research
Portland, Oregon

Judy Knighton, RN, MScN
Clinical Nurse Specialist–Burns
Ross Tilley Burn Centre
Sunnybrook Health Sciences Centre
Toronto, Ontario, Canada

Mary Ann Kolis, RN, MSN, ANP-BC, APNP
Instructor
Gateway Technical College
Kenosha, Wisconsin

Catherine N. Kotecki, RN, PhD, APN
Associate Dean
W. Cary Edwards School of Nursing
Thomas Edison State College
Trenton, New Jersey

Nancy Kupper, RN, MSN
Associate Professor
Tarrant County College
Fort Worth, Texas

Jeffrey Kwong, DNP, MPH, ANP-BC
Assistant Professor of Nursing at CUMC
Program Director, Adult-Gerontology Nurse Practitioner Program
Columbia University
New York, New York

Carol A. Landis, RN, DNSc
Professor
Biobehavioral Nursing and Health Systems
University of Washington
School of Nursing
Seattle, Washington

Susan C. Landis, RN, MSN
Lecturer
Biobehavioral Nursing and Health Systems
University of Washington School of Nursing
Seattle, Washington

Janice Lazear, DNP, CRNP, CDE
Assistant Professor
School of Nursing
University of Maryland
Baltimore, Maryland

Catherine (Kate) Lein, MS, FNP-BC
Assistant Professor
Michigan State University College of Nursing
East Lansing, Michigan

Janet Lenart, RN, MN, MPH
Senior Lecturer
University of Washington School of Nursing
Seattle, Washington

Nancy MacMullen, PhD, APN/CNS, RNC, HR-OB, CNE
Associate Professor
Governors State University
Oak Forest, Illinois

Dorothy (Dottie) M. Mathers, RN, DNP, CNE
Professor
School of Health Sciences
Pennsylvania College of Technology
Williamsport, Pennsylvania

De Ann F. Mitchell, RN, PhD
Professor of Nursing
Tarrant County College
Trinity River East Campus
Fort Worth, Texas

Carolyn Moffa, MSN, FNP-C, CHFN
Clinical Leader
Heart Failure Program
Christiana Care Health System
Newark, Delaware

Janice Neil, RN, PhD
Associate Professor and Chair, Undergraduate Nursing Science Junior Division
College of Nursing
East Carolina University
Greenville, North Carolina

DaiWai Olson, RN, PhD, CCRN
Associate Professor of Neurology and Neurotherapeutics
University of Texas Southwestern
Dallas, Texas

Rosemary C. Polomano, RN, PhD, FAAN
Associate Professor of Pain Practice
Department of Biobehavioral Health Sciences
University of Pennsylvania School of Nursing;
Associate Professor of Anesthesiology and Critical Care
University of Pennsylvania Perelman School of Medicine
Philadelphia, Pennsylvania

Kathleen A. Rich, RN, PhD, CCNS, CCRN-CSC, CNN
Cardiovascular Clinical Specialist
Indiana University Health La Porte Hospital
La Porte, Indiana

Dottie Roberts, RN, MSN, MACI, CMSRN, OCNS-C, CNE
Instructor
University of South Carolina College of Nursing
Columbia, South Carolina

Sandra Irene Rome, RN, MN, AOCN, CNS
Clinical Nurse Specialist
Hematology/Oncology/BMT
Cedars-Sinai Medical Center
Los Angeles, California

Jennifer Saylor, RN, PhD, ACNS-BC
Clinical Instructor
University of Delaware
Wilmington, Delaware

Marilee Schmelzer, RN, PhD
Associate Professor
University of Texas at Arlington College of Nursing
Arlington, Texas

Maureen A. Seckel, RN, APN, MSN, ACNS-BC, CCNS, CCRN
Clinical Nurse Specialist Medical Pulmonary Critical Care
Christiana Care Health System
Newark, Delaware

Virginia (Jennie) Shaw, RN, MSN
Associate Professor
University of Texas Health Science Center School of Nursing
San Antonio, Texas

Anita Jo Shoup, RN, MSN, CNOR
Perioperative Clinical Nurse Specialist
Swedish Edmonds
Edmonds, Washington

Dierdre D. Wipke-Tevis, RN, PhD
Associate Professor
PhD Program Director, Coordinator of Clinical Nurse Specialist Area of Study
Sinclair School of Nursing
University of Missouri
Columbia, Missouri

Mary Wollan, RN, BAN, ONC
Orthopaedic Nurse Educator
Twin Cities Orthopaedic Education Association
Spring Park, Minnesota

Meg Zomorodi, RN, PhD, CNL
Clinical Associate Professor
University of North Carolina at Chapel Hill School of Nursing
Chapel Hill, North Carolina

Damien Zsiros, RN, MSN, CNE, CRNP
Nursing Instructor
The Pennsylvania State University School of Nursing
Fayette/The Eberly Campus
Uniontown, Pennsylvania

PREFACE

The ninth edition of *Medical-Surgical Nursing: Assessment and Management of Clinical Problems* has been thoroughly revised to incorporate the most current medical-surgical nursing information in an easy-to-use format. More than just a textbook, this is a comprehensive resource containing essential information that students need to prepare for lectures, classroom activities, examinations, clinical assignments, and the safe, comprehensive care of patients. In addition to the readable writing style and full-color illustrations, the text and accompanying resources include many special features to help students learn key medical-surgical nursing content, including patient and caregiver teaching, gerontology, collaborative care, cultural and ethnic considerations, patient safety, genetics, nutrition and drug therapy, evidence-based practice, and much more.

The comprehensive and timely content, special features, attractive layout, and student-friendly writing style combine to make this the number one medical-surgical nursing textbook used in more nursing schools than any other medical-surgical nursing textbook.

The strengths of the first eight editions have been retained, including the use of the nursing process as an organizational theme for nursing management. Numerous new features have been added to address some of the rapid changes in practice. Contributors have been selected for their expertise in specific content areas; one or more specialists in the subject area have thoroughly reviewed each chapter to increase accuracy. The editors have undertaken final rewriting and editing to achieve internal consistency. All efforts have been directed toward building on the strengths of the previous edition while preparing an even more effective new edition.

ORGANIZATION

Content is organized into two major divisions. The first division, Section 1 (Chapters 1 through 11), discusses general concepts related to adult patients. The second division, Sections 2 through 12 (Chapters 12 through 69), presents nursing assessment and nursing management of medical-surgical problems.

The various body systems are grouped to reflect their interrelated functions. Each section is organized around two central themes: assessment and management. Chapters dealing with assessment of a body system include a discussion of the following:

1. A brief review of anatomy and physiology, focusing on information that will promote understanding of nursing care
2. Health history and noninvasive physical assessment skills to expand the knowledge base on which treatment decisions are made
3. Common diagnostic studies, expected results, and related nursing responsibilities to provide easily accessible information

Management chapters focus on the pathophysiology, clinical manifestations, diagnostic studies, collaborative care, and nursing management of various diseases and disorders. The nursing management sections are organized into assessment, nursing diagnoses, planning, implementation, and evaluation. To emphasize the importance of patient care in various clinical settings, nursing implementation of all major health problems is organized by the following levels of care:

1. Health Promotion
2. Acute Intervention
3. Ambulatory and Home Care

CLASSIC FEATURES

- **Nursing management** is presented in a consistent and comprehensive format, with headings for Health Promotion, Acute Intervention, and Ambulatory and Home Care. Over 60 nursing care plans on the Evolve website and in the text incorporate Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) in a way that clearly shows the linkages among NIC, NOC, and nursing diagnoses, and applies them to nursing practice.
- **Cultural and ethnic health disparities** content and boxes in the text highlight risk factors and important issues related to the nursing care of various ethnic groups. A special Culturally Competent Care heading denotes cultural and ethnic content related to diseases and disorders. Chapter 2: *Health Disparities and Culturally Competent Care* discusses health status differences among groups of people related to access to care, economic aspects of health care, gender and cultural issues, and disease risk.
- **Collaborative care** is highlighted in special Collaborative Care sections in all management chapters and Collaborative Care tables throughout the text.
- **Coverage on delegation and prioritization** includes the following:
  - Delegation Decisions boxes throughout the text highlight specific topics and skills related to delegation
  - Delegation and priority questions in case studies and Bridge to NCLEX® Examination Questions
  - Nursing interventions throughout the text are listed in order of priority
  - Nursing diagnoses in the nursing care plans are listed in order of priority
- **Focused Assessment boxes** in all assessment chapters provide brief checklists that help students do a more practical "assessment on the run" or bedside approach to assessment. They can be used to evaluate the status of previously identified health problems and monitor for signs of new problems.
- **Safety Alert boxes** highlight important patient safety issues and focus on the National Patient Safety Goals.
- **Pathophysiology Maps** outline complex concepts related to diseases in flowchart format, making them easier to understand.
- **Chapter 8: *Sleep and Sleep Disorders*** expands on this key topic that impacts multiple disorders and body systems as well as nearly every aspect of daily functioning.
- **Patient and caregiver teaching** is an ongoing theme throughout the text. Chapter 4: *Patient and Caregiver Teaching* emphasizes the increasing importance and prevalence of

patient management of chronic illnesses and conditions and the role of the caregiver in patient care.
- **Gerontology and chronic illness** are discussed in Chapter 5: *Chronic Illness and Older Adults,* and included throughout the text under Gerontologic Considerations headings and in Gerontologic Assessment Differences tables.
- **Nutrition** is highlighted throughout the book. Nutritional Therapy tables summarize nutritional interventions and promote healthy lifestyles in patients with various health problems.
- ***Healthy People*** **boxes** present health care goals as they relate to specific disorders such as diabetes and cancer.
- **Extensive drug therapy content** includes Drug Therapy tables and concise Drug Alerts highlighting important safety considerations for key drugs.
- **Genetics in Clinical Practice boxes** summarize the genetic basis, genetic testing, and clinical implications for genetic disorders that affect adults.
- **Gender Differences boxes** discuss how women and men are affected differently by conditions such as pain and hypertension.
- A separate chapter on **complementary and alternative therapies** (CAT) addresses current issues in today's health care settings related to these therapies. Complementary & Alternative Therapies boxes expand on this information and summarize what nurses need to know about therapies such as herbal remedies, acupuncture, and biofeedback.
- **Ethical/Legal Dilemmas boxes** promote critical thinking for timely and sensitive issues that nursing students may deal with in clinical practice—topics such as informed consent, advance directives, and confidentiality.
- **Home care/community-based care** is found in special Ambulatory and Home Care sections in the nursing management chapters.
- **Emergency Management tables** outline the emergency treatment of health problems most likely to require emergency intervention.
- **Assessment Abnormalities tables** in assessment chapters alert the nurse to frequently encountered abnormalities and their possible etiologies.
- **Nursing Assessment tables** summarize the key subjective and objective data related to common diseases. Subjective data are organized by functional health patterns.
- **Health History tables** in assessment chapters present key questions to ask patients related to a specific disease or disorder.
- Student-friendly pedagogy includes the following:
  - **Learning Outcomes** and **Key Terms** at the beginning of each chapter help students identify the key content for that chapter.
  - **Evolve website boxes** in chapter openers alert students to supplemental online content and exercises, making it easy for students to facilitate online learning.
  - **Bridge to NCLEX® Examination Questions** at the end of each chapter are matched to the learning outcomes and help students learn the important points in the chapter. Answers are provided just below the questions for immediate feedback, and rationales are provided on the Evolve website.
  - **Case Studies with photos** at the end of chapters bring patients to life. Multiple disorders are incorporated so students learn how to prioritize care and manage patients in the clinical setting. Discussion questions with a focus on prioritization, delegation, and evidence-based practice are included. Answer guidelines are provided on the Evolve website.
- **Resources** at the end of most chapters include websites for nursing and health care organizations that provide patient teaching and disease and disorder information.
- A **glossary** of key terms and definitions is provided at the back of the text. An expanded version of the glossary with audio pronunciations is included on the Evolve website.

NEW FEATURES

- Once again, each chapter has been carefully revised to ensure a **lower reading level** and more reader-friendly and understandable content than ever. Essential content has been streamlined to help students more effectively learn critical content.
- **Unfolding case studies** in every assessment chapter are an engaging tool that help students apply nursing concepts to real-life patient care.
- **Managing Multiple Patients Case Studies** at the end of each section help students learn to prioritize, delegate, and manage patient care.
- **Informatics boxes** discuss how technology is used by nurses and patients in health care settings.
- **Expanded evidence-based practice content** includes new Applying the Evidence boxes, updated Translating Research Into Practice boxes, and evidence-based practice-focused questions in the case studies.
- **Safety Alerts** have been expanded throughout the book to cover surveillance for high-risk situations.
- New content in Chapter 1 covers **teamwork and interdisciplinary teams,** as this is a key component of QSEN.
- An **increased focus on genetics** includes:
  - A new **genetics chapter** that focuses on practical application of nursing care as it relates to this important topic
  - **Genetic Risk Alerts** in the assessment chapters call attention to important genetic risks
  - **Genetic Link headings** in the management chapters highlight the specific genetic bases of many disorders
- **Expanded coverage of delegation** includes additional Delegation Decision boxes covering issues such as hypertension and postoperative patient care.
- Coverage of **legal considerations has been expanded** in the revised Ethical/Legal Dilemmas boxes.
- **New art** enhances the book's visual appeal and lends a more contemporary look throughout.

LEARNING SUPPLEMENTS FOR STUDENTS

- The handy ***Clinical Companion*** presents approximately 200 common medical-surgical conditions and procedures in a concise, alphabetical format for quick clinical reference. Designed for portability, this popular reference includes the essential, need-to-know information for treatments and procedures in which nurses play a major role. An attractive and functional two-color design highlights key information for quick, easy reference.

- An exceptionally thorough ***Study Guide*** contains over 500 pages of review material that reflect the content found in the book. It features a wide variety of clinically relevant exercises and activities, including NCLEX-format multiple choice and alternate format questions, case studies, anatomy review, critical thinking activities, and much more. It features an attractive two-color design and many alternate-item format questions to better prepare students for the NCLEX examination. An answer key is included to provide students with immediate feedback as they study.
- The **Evolve Student Resources** are available online at *http://evolve.elsevier.com/Lewis/medsurg* and include the following valuable learning aids organized by chapter:
  - Printable Key Points summaries for each chapter
  - 1000 NCLEX Examination Review Questions
  - Pre-Tests for every chapter
  - Answer Guidelines to the case studies in the textbook
  - Rationales for the Bridge to NCLEX® Examination Questions in the textbook
  - 55 Interactive Case Studies with state-of-the-art animations and a variety of learning activities, which provide students with immediate feedback. Ten of the case studies are enhanced with photos and narration of the clinical scenarios.
  - Customizable Nursing Care Plans
  - Concept Map Creator and concept maps for selected case studies in the textbook
  - Audio glossary of key terms, available as comprehensive alphabetical glossary and organized by chapter
  - Stress-Busting Kit
  - Animations, video clips, and audio clips
  - Fluids and Electrolytes Tutorial
  - Content Updates
  - Additional resources, including tables, figures, and clinical references
- **Virtual Clinical Excursions** (VCE) is an exciting learning tool that brings learning to life in a "virtual" hospital setting. VCE simulates a realistic, yet safe, nursing environment where the routine and rigors of the average clinical rotation abound. Students can conduct a complete assessment of a patient and set priorities for care, collect data, analyze and interpret data, prepare and administer medications, and reach conclusions about complex problems. Each lesson has a textbook reading assignment and online activities based on "visiting" patients in the hospital. Instructors receive an implementation manual with directions for using VCE as a teaching tool.
- More than just words on a screen, **Pageburst eBooks** come with a wealth of built-in study tools and interactive functionality to help students better connect with the course material and their instructors. Plus, with the ability to fit an entire library of books on one portable device, Pageburst gives students the ability to study when, where, and how they want.

TEACHING SUPPLEMENTS FOR INSTRUCTORS

- The **Evolve Instructor Resources** (available online at *http://evolve.elsevier.com/Lewis/medsurg*) remain the most comprehensive set of instructor's materials available, containing the following:
  - **TEACH for Nurses Lesson Plans** with electronic resources organized by chapter to help instructors develop and manage the course curriculum. This exciting resource includes:
    - Objectives
    - Teaching focus
    - Key terms
    - Nursing curriculum standards
    - Student and instructor chapter resource listings
    - Detailed chapter outlines
    - Teaching strategies with learning activities and links to resources in the image collection, PowerPoint presentations, animations, etc.
    - Case studies with answer guidelines
  - The **Test Bank** features over 2000 NCLEX Examination test questions with text page references and answers coded for NCLEX Client Needs category, nursing process, and cognitive level. The ninth edition test bank has been completely updated and reviewed, and it now includes hundreds of prioritization, delegation, and multiple patient questions. All alternate item format questions are included. The ExamView software allows instructors to create new tests; edit, add, and delete test questions; sort questions by NCLEX category, cognitive level, nursing process step, and question type; and administer and grade online tests.
  - The **Image Collection** contains more than 800 full-color images from the text for use in lectures.
  - An extensive collection of **PowerPoint Presentations** includes over 125 different presentations focused on the most common diseases and disorders. The presentations have been thoroughly revised to include helpful instructor notes/teaching tips, unfolding case studies, new illustrations and photos not found in the book, new animations, and updated audience response questions for use with iClicker and other audience response systems.
  - Course management system.
  - Access to all student resources listed above.
- The **Simulation Learning System (SLS)** is an online toolkit that helps instructors and facilitators effectively incorporate medium- to high-fidelity simulation into their nursing curriculum. Detailed patient scenarios promote and enhance the clinical decision-making skills of students at all levels. The SLS provides detailed instructions for preparation and implementation of the simulation experience, debriefing questions that encourage critical thinking, and learning resources to reinforce student comprehension. Each scenario in the SLS complements the textbook content and helps bridge the gap between lecture and clinical. The SLS provides the perfect environment for students to practice what they are learning in the text for a true-to-life, hands-on learning experience.

ACKNOWLEDGMENTS

The editors are especially grateful to many people at Elsevier who assisted with this major revision effort. In particular, we wish to thank the team of Kristin Geen, Jamie Randall, Mary Stueck, Jeff Patterson, and Maggie Reid. In addition, we want to thank the marketing team of Pat Crowe, Katie Schlesinger, and Becky McBride.

Special thanks and appreciation go to Peter Bonner who assisted with many details of manuscript preparation and review and photography for the book and interactive case studies.

We are particularly indebted to the faculty, nurses, and student nurses who have put their faith in our book to assist them on their path to excellence. The increasing use of this book throughout the United States, Canada, Australia, and other parts of the world has been gratifying. We appreciate the many users who have shared their comments and suggestions on the previous editions. All feedback is welcome.

We also wish to thank our contributors and reviewers for their assistance with the revision process. We sincerely hope that this book will assist both students and clinicians in practicing truly professional nursing.

Perioperative Care, Section 3, p. 366
Problems of Ingestion, Digestion, Absorption, and Elimination, Section 8, p. 1044
Problems of Oxygenation: Perfusion, Section 7, p. 863
Problems of Oxygenation: Transport, Section 6, p. 684
Problems of Oxygenation: Ventilation, Section 5, p. 611
Problems of Urinary Function, Section 9, p. 1132
Problems Related to Altered Sensory Input, Section 4, p. 473
Problems Related to Movement and Coordination, Section 11, p. 1596
Problems Related to Regulatory and Reproductive Mechanisms, Section 10, p. 1333

Assessment Case Studies

Cardiovascular System, 32, p. 692
Endocrine System, 48, p. 1141
Gastrointestinal System, 39, p. 872
Hematologic System, 30, p. 620
Integumentary System, 23, p. 418
Musculoskeletal System, 62, p. 1494
Nervous System, 56, p. 1344
Reproductive System, 51, p. 1226
Respiratory System, 26, p. 482
Urinary System, 45, p. 1051
Visual and Auditory Systems, 21, p. 372

COLLABORATIVE CARE TABLES

Acute Kidney Injury, 47, p. 1105
Acute Pancreatitis, 44, p. 1032
Acute Pericarditis, 37, p. 816
Acute Pulmonary Embolism, 28, p. 552
Acute Pyelonephritis, 46, p. 1070
Acute Respiratory Distress Syndrome, 68, p. 1669
Acute Respiratory Failure, 68, p. 1661
Addison's Disease, 50, p. 1212
Alzheimer's Disease, 60, p. 1451

Amputation, 63, p. 1530
Aortic Dissection, 38, p. 846
Asthma, 29, p. 566
Bacterial Meningitis, 57, p. 1382
Benign Prostatic Hyperplasia, 55, p. 1309
Bladder Cancer, 46, p. 1086
Breast Cancer, 52, p. 1247
Burn Injury, 25, p. 460
Cardiomyopathy, 37, p. 827
Cataract, 22, p. 393
Cervical Cord Injury, 61, p. 1474
Chlamydial Infection, 53, p. 1267
Cholelithiasis and Acute Cholecystitis, 44, p. 1038
Chronic Kidney Disease, 47, p. 1112
Chronic Obstructive Pulmonary Disease (COPD), 29, p. 588
Chronic Otitis Media, 22, p. 404
Cirrhosis of the Liver, 44, p. 1022
Colorectal Cancer, 43, p. 987
Cor Pulmonale, 28, p. 556
Cushing Syndrome, 50, p. 1209

Diabetic Ketoacidosis (DKA) and Hyperosmolar Hyperglycemic Syndrome (HHS), 49, p. 1176
Diverticulosis and Diverticulitis, 43, p. 995
Endometriosis, 54, p. 1290
Erectile Dysfunction, 55, p. 1328
Esophageal Cancer, 42, p. 937
Fractures, 63, p. 1513
Gastroesophageal Reflux Disease (GERD) and Hiatal Hernia, 42, p. 933
Genital Herpes, 53, p. 1269
Glaucoma, 22, p. 399
Gonorrhea, 53, p. 1264
Gout, 65, p. 1577
Headaches, 59, p. 1417
Heart Failure, 35, p. 773
Hypertension, 33, p. 715
Hyperthyroidism, 50, p. 1198
Hypoglycemia, 49, p. 1179
Hypothyroidism, 50, p. 1202
Increased Intracranial Pressure, 57, p. 1361
Infertility, 54, p. 1277
Inflammatory Bowel Disease, 43, p. 978
Insomnia, 8, p. 103
Intervertebral Disc Disease, 64, p. 1549
Iron-Deficiency Anemia, 31, p. 638
Lung Cancer, 28, p. 538
Ménière's Disease, 22, p. 406
Multiple Sclerosis, 59, p. 1430
Myasthenia Gravis, 59, p. 1438
Neurogenic Bladder, 61, p. 1481
Neutropenia, 31, p. 662
Obesity, 41, p. 913
Oral Cancer, 42, p. 930
Osteoarthritis, 65, p. 1564
Osteoporosis, 64, p. 1555
Otosclerosis, 22, p. 405
Ovarian Cancer, 54, p. 1295
Parkinson's Disease, 59, p. 1434
Peptic Ulcer Disease, 42, p. 946
Peripheral Artery Disease, 38, p. 836
Peritonitis, 43, p. 975
Pneumonia, 28, p. 525
Premenstrual Syndrome (PMS), 54, p. 1279
Prostate Cancer, 55, p. 1317
Pulmonary Tuberculosis, 28, p. 531
Renal Cell Carcinoma, 46, p. 1084
Retinal Detachment, 22, p. 396
Rheumatic Fever, 37, p. 819
Rheumatoid Arthritis, 65, p. 1572
Scleroderma, 65, p. 1588
Seizure Disorders and Epilepsy, 59, p. 1422
Shock, 67, p. 1645
Stomach Cancer, 42, p. 952
Stroke, 58, p. 1396
Syphilis, 53, p. 1266
Systemic Lupus Erythematosus, 65, p. 1585
Thrombocytopenia, 31, p. 653
Trigeminal Neuralgia, 61, p. 1464
Urinary Tract Infection, 46, p. 1067
Valvular Heart Disease, 37, p. 823
Viral Hepatitis, 44, p. 1012

COMPLEMENTARY & ALTERNATIVE THERAPIES BOXES

Acupuncture, 65, p. 1565
Assessment of Use of Herbs and Dietary Supplements, 3, p. 39
Biofeedback, 46, p. 1087
Complementary & Alternative Therapies Boxes Throughout Book, 6, p. 81
Echinacea, 27, p. 502
Fish Oil and Omega-3 Fatty Acids, 33, p. 716
Ginger, 42, p. 927
Glucosamine and Chondroitin, 65, p. 1565
Hawthorn, 35, p. 777
Herbal and Dietary Supplements That May Affect Clotting, 38, p. 851
Herbal Products and Surgery, 18, p. 320
Herbs and Supplements for Menopause, 54, p. 1285
Herbs and Supplements That May Affect Blood Glucose, 49, p. 1174
Imagery, 52, p. 1255
Kava, 7, p. 97
Lipid-Lowering Agents, 34, p. 738
Melatonin, 8, p. 104
Milk Thistle (Silymarin), 44, p. 1012
Music Therapy, 19, p. 337
St. John's Wort, 7, p. 96
Yoga, 6, p. 83
Zinc, 27, p. 505

CULTURAL & ETHNIC HEALTH DISPARITIES BOXES

Arthritis and Connective Tissue Disorders, 65, p. 1569
Brain Tumors, 57, p. 1375
Breast Cancer, 52, p. 1253
Cancer, 16, p. 282
Cancers of the Female Reproductive System, 54, p. 1292
Cancers of the Male Reproductive System, 55, p. 1315
Chronic Kidney Disease, 47, p. 1108
Colorectal Cancer, 43, p. 986
Coronary Artery Disease, 34, p. 732

Cultural & Ethnic Health Disparities Boxes Throughout Book, 2, p. 21
Diabetes Mellitus, 49, p. 1170
Heart Failure, 35, p. 767
Hematologic Problems, 31, p. 633
Hypertension, 33, p. 710
Immunizations in Hispanics, 27, p. 504
Inflammatory Bowel Disease, 43, p. 976
Integumentary Problems, 24, p. 429
Liver, Pancreas, and Gallbladder Disorders, 44, p. 1017
Lung Cancer, 28, p. 536
Obesity, 41, p. 908
Obstructive Pulmonary Diseases, 29, p. 561
Oral, Pharyngeal, and Esophageal Problems, 42, p. 929
Osteoporosis, 64, p. 1554
Sexually Transmitted Infections, 53, p. 1262
Stroke, 58, p. 1390
Tuberculosis, 28, p. 528
Urologic Disorders, 46, p. 1065
Visual and Auditory Problems, 22, p. 388

DELEGATION DECISIONS BOXES

Assessment and Data Collection, 3, p. 38
Blood Transfusions, 31, p. 676
Cardiac Catheterization and Percutaneous Coronary Intervention (PCI), 34, p. 758
Caring for the Incontinent Patient, 46, p. 1091
Caring for the Patient Receiving Bladder Irrigation, 55, p. 1320
Caring for the Patient Requiring Mechanical Ventilation, 66, p. 1625
Caring for the Patient With an Acute Stroke, 58, p. 1405
Caring for the Patient With Alzheimer's Disease, 60, p. 1455
Caring for the Patient With a Cast or Traction, 63, p. 1514
Caring for the Patient With Chronic Venous Insufficiency, 38, p. 858
Caring for the Patient With Diabetes Mellitus, 49, p. 1185
Caring for the Patient With Hypertension, 33, p. 724
Caring for the Patient With Neutropenia, 31, p. 661
Caring for the Patient With a Seizure Disorder, 59, p. 1426
Caring for the Patient With Venous Thromboembolism (VTE), 38, p. 855
Corrective Lenses and Hearing Aids, 22, p. 411
Delegation Decisions Boxes Throughout Book, 1, p. 16
Intravenous Therapy, 17, p. 309
Nasogastric and Gastric Tubes and Enteral Feedings, 40, p. 900
Ostomy Care, 43, p. 994
Oxygen Administration, 29, p. 592
Pain, 9, p. 134
Postoperative Patient, 20, p. 354
Skin Care, 24, p. 446
Suctioning and Tracheostomy Care, 27, p. 518
Urinary Catheters, 46, p. 1093
Wound Care, 12, p. 183

DIAGNOSTIC STUDIES TABLES

Acute Pancreatitis, 44, p. 1031
Auditory System, 21, p. 383
Cardiovascular System, 32, p. 699
Clotting Studies, 30, p. 627
Complete Blood Count Studies, 30, p. 626
Endocrine System, 48, p. 1147
Gastrointestinal System, 39, p. 879
Headaches, 59, p. 1415
Hematologic System, 30, p. 629
Integumentary System, 23, p. 425
Laboratory Changes in Shock, 67, p. 1634
Liver Function Tests, 39, p. 884
Male and Female Reproductive Systems, 51, p. 1233
Miscellaneous Blood Studies, 30, p. 628
Musculoskeletal System, 62, p. 1501
Nervous System, 56, p. 1352
Respiratory System, 26, p. 491
Stroke, 58, p. 1395
Urinalysis, 45, p. 1062
Urinary System, 45, p. 1056
Venous Thromboembolism, 38, p. 850
Visual System, 21, p. 378

DRUG THERAPY TABLES

Acute and Chronic Glaucoma, 22, p. 400
Acute and Chronic Pancreatitis, 44, p. 1032
Acute Gastrointestinal Bleeding, 42, p. 955
Adjuncts to General Anesthesia, 19, p. 344
Adjuvant Drugs Used for Pain, 9, p. 128
Alzheimer's Disease, 60, p. 1452
Androgen Deprivation Therapy for Prostate Cancer, 55, p. 1319
Anticoagulant Therapy, 38, p. 851
Anticoagulant Therapy for Atrial Fibrillation, 36, p. 797
Antidiarrheal Drugs, 43, p. 963
Antidysrhythmia Drugs, 36, p. 801
Arthritis and Connective Tissue Disorders, 65, p. 1565
Asthma and Chronic Obstructive Pulmonary Disease (COPD), 29, p. 570
Bacterial Community-Acquired Pneumonia, 28, p. 526
Biologic and Targeted Therapy, 16, p. 272
Breast Cancer, 52, p. 1251
Burn Care, 25, p. 463
Chemotherapy Drugs, 16, p. 259
Chronic Stable Angina and Acute Coronary Syndrome, 34, p. 744
Cirrhosis, 44, p. 1024
Combination Therapy for Hypertension, 33, p. 721
Common Bases for Topical Medications, 24, p. 440
Common Causes of Medication Errors by Older Adults, 5, p. 73
Commonly Used Preoperative Medications, 18, p. 329
Constipation, 43, p. 967
Diseases and Disorders Treated With Corticosteroids, 50, p. 1213
Drugs Affecting Lower Urinary Tract Function, 46, p. 1087
Drugs That May Cause Photosensitivity, 24, p. 429
Effects and Side Effects of Corticosteroids, 50, p. 1213
Gastroesophageal Reflux Disease (GERD) and Peptic Ulcer Disease (PUD), 42, p. 934
General Anesthesia, 19, p. 343
Heart Failure, 35, p. 774
Helicobacter pylori Infection, 42, p. 942
Hematopoietic Growth Factors Used in Cancer Treatment, 16, p. 274
HIV Infection, 15, p. 237

Hyperlipidemia, 34, p. 739
Hypertension, 33, p. 717
Immunosuppressive Therapy, 14, p. 222
Infertility, 54, p. 1277
Inflammation and Healing, 12, p. 176
Inflammatory Bowel Disease, 43, p. 979
Insomnia, 8, p. 104
Insulin Regimens, 49, p. 1159
Latent Tuberculosis Infection Regimens, 28, p. 532
Leukemia, 31, p. 667
Long-Term Control Versus Quick Relief of Asthma, 29, p. 568
Managing Side Effects of Pain Medications, 9, p. 123
Medication Guidelines for Stable COPD, 29, p. 589
Medication Use by Older Adults, 5, p. 74
Methods of Chemotherapy Administration, 16, p. 261
Multiple Sclerosis, 59, p. 1430
Narcolepsy, 8, p. 107
Nausea and Vomiting, 42, p. 926
Opioid Analgesics, 9, p. 125
Oral Agents and Noninsulin Injectable Agents, 49, p. 1164
Parkinson's Disease, 59, p. 1435
Pulmonary Hypertension, 28, p. 555
Replacement Factors for Hemophilia, 31, p. 656
Rhinitis and Sinusitis, 27, p. 501
Seizure Disorders and Epilepsy, 59, p. 1423
Selected Nonopioid Analgesics, 9, p. 123
Shock, 67, p. 1643
Smoking Cessation, 11, p. 159
Tuberculosis (TB), 28, p. 531
Tuberculosis Disease Regimens, 28, p. 531
Types of Insulin, 49, p. 1158
Voiding Dysfunction, 46, p. 1091

EMERGENCY MANAGEMENT TABLES

Abdominal Trauma, 43, p. 973
Acute Abdominal Pain, 43, p. 971
Acute Soft Tissue Injury, 63, p. 1507
Anaphylactic Shock, 14, p. 214
Chemical Burns, 25, p. 457
Chest Pain, 34, p. 750
Chest Trauma, 28, p. 541
Cocaine and Amphetamine Toxicity, 11, p. 164
Depressant Drug Overdose, 11, p. 164
Diabetic Ketoacidosis, 49, p. 1177
Dysrhythmias, 36, p. 793
Electrical Burns, 25, p. 456
Emergency Management Tables, 69, p. 1675
Eye Injury, 22, p. 390
Fractured Extremity, 63, p. 1518
Head Injury, 57, p. 1372
Hyperthermia, 69, p. 1683
Hypothermia, 69, p. 1685
Inhalation Injury, 25, p. 456
Sexual Assault, 54, p. 1302
Shock, 67, p. 1641
Spinal Cord Injury, 61, p. 1474
Stroke, 58, p. 1398
Submersion Injuries, 69, p. 1687
Thermal Burns, 25, p. 455
Thoracic Injuries, 28, p. 542
Tonic-Clonic Seizures, 59, p. 1423

ETHICAL/LEGAL DILEMMAS BOXES

EVIDENCE-BASED PRACTICE

Translating Research Into Practice Boxes

Are Decision Aids Helpful in Making Decisions About Health Care?, 4, p. 55
Are Proton Pump Inhibitors Associated With Increased Risk of Diarrhea?, 42, p. 933

Bariatric Surgery for Obese Adults With Type 2 Diabetes, 49, p. 1170
Can Botulinum Toxin A Prevent Headaches?, 59, p. 1418
Can Exercise Help Depression in Heart Failure Patients?, 35, p. 775
Can Exercise Improve Physical Fitness in Chronic Kidney Disease?, 47, p. 1113
Can Mirror Therapy Improve Functioning After Stroke?, 58, p. 1396
Can Yoga Improve Chronic Low Back Pain?, 64, p. 1547
Do Cranberry Products Prevent Urinary Tract Infections?, 46, p. 1068
Do Exercise-Based Cardiac Rehabilitation Programs Improve Outcomes?, 34, p. 759
Do Lifestyle Changes and Cardiovascular Medication Improve Erectile Dysfunction?, 55, p. 1327
Do Probiotics Prevent Upper Respiratory Tract Infections?, 27, p. 503
Do Vitamin D Supplements Improve Strength in Older Adults?, 63, p. 1519
Does Cognitive Reframing Help Caregivers of Patients With Dementia?, 60, p. 1457
Does Dietary Fat Modification Improve Cardiovascular Disease Outcomes?, 34, p. 738
Does Intermittent Iron Supplementation Improve Anemia?, 31, p. 639
Does Nutritional Education Improve Functional Outcomes in Older Adults?, 40, p. 895
Does the Type of Enteral Feeding Affect Outcomes in Burn Patients?, 25, p. 463
Does Timing of Ambulation Affect Patient Safety After Percutaneous Coronary Intervention?, 34, p. 746
Does Timing of Tracheotomy Affect Critically Ill Patient Outcomes?, 66, p. 1614
How Effective is Subglottic Secretion Drainage on Ventilator-Associated Pneumonia?, 68, p. 1668
Is Sun-Protective Counseling Effective?, 24, p. 428
What Is the Effect of Physical Activity in Cancer Survivors?, 52, p. 1252
What Is the Effect of Tap Water on Wound Cleansing?, 12, p. 182
What is the Effectiveness of Chronic Illness Strategies for Asian/Pacific Islanders?, 5, p. 64
What Strategies Improve Screening Rates for Repeat Chlamydial Infections?, 53, p. 1266
Which Interventions Improve Well-Being in Lung Cancer?, 28, p. 537

FOCUSED ASSESSMENT BOXES

Auditory System, 21, p. 379
Cardiovascular System, 32, p. 698

LEARNING OUTCOMES

1. Describe professional nursing practice in terms of domain, definitions, and recipients of care.
2. Compare the different scopes of practice available to professional nurses.
3. Analyze the effect of expanding technology and knowledge, changing populations, consumerism, and evolving health care systems on professional nursing practice.
4. Describe the role of critical thinking skills and use of the nursing process to provide patient-centered care.
5. Explain how standardized nursing terminologies for nursing diagnoses, patient outcomes, and nursing interventions can be used and linked.
6. Evaluate the role of informatics and technology in nursing practice.
7. Apply concepts of evidence-based practice to nursing practice.
8. Discuss the role of integrating safety and quality improvement processes into nursing practice.
9. Explore the role of the professional nurse in delegating care to licensed practical/vocational nurses and unlicensed assistive personnel.

This chapter presents an overview of professional nursing practice, discussing the wide variety of roles and responsibilities nurses fulfill to meet the health care needs of society.

PROFESSIONAL NURSING PRACTICE

Domain of Nursing Practice

Nursing practice today consists of a wide variety of roles and responsibilities necessary to meet society's health care needs. As a nurse, you are the frontline professional of health care (Fig. 1-1). You practice in virtually all health care settings and communities across the country. You have never been more important to health care than you are today. As a nurse, you (1) offer skilled care to those recuperating from illness or injury, (2) advocate for patients' rights, (3) teach patients so that they can make informed decisions, (4) support patients and their caregivers at critical times, and (5) help them navigate the increasingly complex health care system. Although the majority of nurses are employed in acute care facilities, many nurses practice in long-term care, home care, primary and preventive care, ambulatory clinics, and community health. Wherever you practice, recipients of your care include individuals, groups, families, or communities.

The American Nurses Association (ANA) declares that the authority for the practice of nursing is based on a contract with society that acknowledges professional rights and respon-

Reviewed by Claudia C Grobbel, RN, DNP, Assistant Professor, Oakland University, Rochester, Michigan; Elizabeth E. Hand, RN, MS, Adjunct Faculty, Tulsa Community College, School of Nursing, Tulsa, Oklahoma; and Patricia O'Brien, RN, ACNS-BC, MA, MSN, Retired Instructor, University of New Mexico, College of Nursing and Central New Mexico Community College, Albuquerque, New Mexico.

FIG. 1-1 Nurses are frontline professionals of health care. (Thomas Northcut/Digital Vision/Thinkstock)

sibilities, as well as mechanisms for public accountability.[1] The knowledge and skills that comprise nursing practice are derived from society's expectations and needs. Nursing practice continues to evolve according to society's health needs and as knowledge and technology expand. This chapter introduces concepts and factors that affect professional nursing practice.

Definitions of Nursing

Several well-known definitions of nursing indicate that the basic themes of health, illness, and caring have existed since Florence Nightingale described nursing. Following are two such examples:

- Nursing is putting the patient in the best condition for nature to act (Nightingale).[2]
- The nurse's unique function is to assist patients, sick or well, in the performance of those activities contributing to health or its recovery (or to peaceful death) that they would perform unaided if they had the necessary strength, will, or knowledge—and to do this in such a way as to help them gain independence as rapidly as possible (Henderson).[3]

In 1980 the ANA defined **nursing** as "the diagnosis and treatment of human responses to actual and potential health problems."[1] In this context, a nurse caring for a person with a fractured hip would focus on the patient's possible responses to immobility, pain, and loss of independence.

The widely accepted ANA definition of nursing was reaffirmed in the 2010 edition of the ANA's *Nursing: A Social Policy Statement* to reflect the continuing evolution of nursing practice:

> ***Nursing*** *is the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations.*[1]

This definition reflects nurses' increasing role in promoting health and wellness and advocating for the recipients of care.

Nursing's View of Humanity

Nursing theorists are in widespread agreement that an individual has physiologic (or biophysical), psychologic (or emotional), sociocultural (or interpersonal), spiritual, and environmental components or dimensions. In this text the human individual is considered "a biopsychosocial spiritual being in constant interaction with a changing environment."[4] The individual is composed of dimensions that are interrelated and not separate entities. Thus a problem in one dimension may affect one or more of the other dimensions. An individual's behavior is meaningful and oriented toward fulfilling needs, coping with stress, and developing one's self. However, at times an individual needs help to meet these needs, cope successfully, or develop his or her unique potential.

Scope of Nursing Practice

Like all health care professions, nursing's scope of practice has a flexible boundary that reflects the changing needs of society and advancement of knowledge. The essential core of nursing practice is to deliver holistic, patient-centered care. It includes assessment and evaluation, administration of a variety of interventions, patient and family teaching, and being a member of the interdisciplinary (also referred to as the interprofessional) health care team.

The extent that individual nurses engage in the scope of practice depends on their educational preparation, experience, and role, and is guided by individual state laws. To enter into practice, a nurse must complete an accredited program and pass an examination verifying the nurse has the skills necessary to provide competent care. Entry-level nurses with associate or baccalaureate degrees are prepared to function as generalists. At this level, nurses provide direct health care and focus on ensuring coordinated and comprehensive care to patients in a variety of settings. They work collaboratively with other health care providers to manage the needs of individuals and groups.[5,6]

With experience and continued study, nurses may specialize in an area of practice. Certification is a formal way for nurses to obtain professional recognition for their expertise in a specialty area. A variety of nursing organizations offer certification in a number of nursing specialties.[7] Certification usually requires a certain amount of clinical experience and successful completion of an examination. Recertification usually requires ongoing clinical experience and continuing education. Common nursing specialties include ambulatory care; cardiovascular care; critical care; women's health; diabetes education; nursing informatics; and geriatric, medical-surgical, perinatal, emergency, psychiatric/mental health, and community health nursing.

Additional formal education and experience can prepare nurses for advanced practice. An **advanced practice nurse (APN)** or *advanced practice registered nurse (APRN)* is a nurse with at least a master's degree in nursing; advanced education in pathophysiology, pharmacology, and health assessment; and expertise in a specialized area of practice. Examples of APNs/APRNs are clinical nurse specialists, clinical nurse leaders, nurse practitioners, nurse midwives, and nurse anesthetists. In addition to managing and delivering direct patient care, APNs/APRNs have roles in health promotion, case management, administration, research, and interdisciplinary health systems.[7] Nurses with a PhD typically serve as faculty in schools of nursing, policy analysts, and researchers. However, they are being increasingly employed in clinical settings as clinical experts and health care system executives.

In response to patient care needs and in anticipation of the needs of the current and future health care system, the doctor-

ate of nursing practice (DNP) degree was endorsed in 2004 by the American Association of Colleges of Nursing (AACN). The DNP moves the educational preparation for advanced nursing practice from the master's degree to the doctoral level. It is designed for nurses seeking a practice-focused terminal degree in nursing. The DNP degree moves nursing in the direction of other health professions that offer practice doctorates (e.g., pharmacy [PharmD], psychology [PsyD], and physical therapy [DPT]).[8]

INFLUENCES ON PROFESSIONAL NURSING PRACTICE

Complex Health Care Environments

Expanding Knowledge and Technology. Rapidly changing technology and dramatically expanding knowledge are adding to the complexity of health care environments. Advanced communication technologies have created a more global environment that affects the delivery of health care worldwide. The number and complexity of patient care technologies are transforming how care is delivered. The human genome project and advances in genetics affect the prevention, diagnosis, and treatment of health problems. With advances in knowledge, ethical dilemmas and controversy arise regarding the use of new scientific knowledge and the disparities that exist in patients' access to more technologically advanced health care. Throughout this book, expanding knowledge and technology's impact on nursing practice are highlighted in genetics, informatics, and ethical/legal boxes.

Diverse Populations. Patient populations are more diverse than ever. Americans are living longer, in part due to advances in medical science, technology, and health care delivery. As the population ages, the number of patients with chronic conditions increases. Unlike those who receive acute, episodic care, patients with chronic conditions have a multitude of needs. They see a variety of health care providers in various settings over an extended period. Nurses are also caring for a more culturally and ethnically diverse population. Immigrants, particularly undocumented immigrants and refugees, often lack the resources necessary to access health care. Inability to pay for health care is associated with a tendency to delay seeking care, resulting in illnesses that are more serious. Boxes throughout this book emphasize the influence of such factors as gender, culture, and ethnicity on nursing practice.

Consumerism. Health care is a consumer-focused business. Patients today are active participants in their health care and expect high-quality, coordinated, and financially reasonable care. Health information is readily available. Many patients eagerly seek information about their health problems and health care from media and Internet sources. They gather information so that they can have a voice in making decisions about their health care. As a nurse, you must be able to help patients access and use appropriate health care information (Fig. 1-2).

Influences on Health Care Systems

Health Care Financing. Many changes in health care systems that influence nursing care delivery were initiated by the government, employers, insurance companies, and regulating agencies in an effort to provide more cost-effective health care. Historically, the most notable event related to changing reimbursement patterns was the institution of prospective payment systems in the Medicare program. With these changes, hospitals were no longer reimbursed for all costs. Instead, payment for hospital services for Medicare patients was based on flat fees determined by the diseases and problems treated during the admission. Private and other public health care systems followed suit by introducing managed care systems that use prospective payment as a means of offering cost-effective health care delivery. In health maintenance organizations (HMOs) and

ETHICAL/LEGAL DILEMMAS

Social Networking: HIPAA Violation

Situation

You log into a closed group on a social networking site and read a posting from a fellow nursing student. The posting describes in detail the complex care the student provided to an older patient in a local hospital the previous day. The student comments on how stressful the day was and asks for advice on how to deal with similar patients in the future.

Ethical/Legal Points for Consideration

- Protecting and maintaining patient privacy and confidentiality are basic obligations defined in the Nursing Code of Ethics, which nurses and nursing students should uphold.
- As outlined in the Health Insurance Portability and Accountability Act (HIPAA), a patient's private health information is any information that relates to the person's past, present, or future physical or mental health. This includes not only specific details such as a patient's name or picture, but also information that gives enough details that someone may be able to identify that person.
- You may unintentionally breach privacy or confidentiality by posting patient information (diagnosis, condition, or situation) on a social networking site. Using privacy settings or being in a closed group does not guarantee the secrecy of posted information. Others can copy and share any post without your knowledge.
- Potential consequences for improperly using social networking vary based on the situation. These may include dismissal from a nursing program or civil and criminal actions.
- A student nurse who experienced a stressful day and was looking for advice and support from peers (e.g., "Today my patient died. I wanted to cry.") could share the experience by clearly limiting the posts to the student's personal perspective and not sharing any identifying information.

Discussion Questions

1. How would you deal with the situation involving the fellow nursing student?
2. How would you handle a situation where you observed a staff member who violated HIPAA?

FIG. 1-2 The patient, family, and nurse collaborate as part of coordinating high-quality care. (Hemera/Thinkstock)

preferred provider organizations (PPOs), charges are negotiated in advance of the delivery of care using predetermined reimbursement rates or capitation fees for medical care, hospitalization, and other health care services.

These same third-party payers demand outcome-based quality care that is provided at a price affordable for both individuals and society. Payment for health care services or pay-for-performance programs reimburse hospitals for their performance on quality-of-care measures. These measures include clinical outcomes, patient safety, patient satisfaction, adherence to evidence-based practice, and adoption of information technology. Payment for care can be withheld if a patient develops certain health care conditions during a hospital stay (e.g., pressure ulcer) or if something happens to the patient that is considered preventable (e.g., acquiring a catheter-related urinary tract infection).[9]

Healthy People* Initiative.** For the past 30 years the U.S. government has been active in establishing goals and objectives for promoting health and health care delivery for the nation through an initiative known as *Healthy People*.[10] The vision of ***Healthy People is a society in which all people live long, healthy lives. *Healthy People* is a broad-based program that involves government, private, public, and nonprofit organizations. Individuals, groups, and organizations are encouraged to integrate *Healthy People* goals and focus areas into current programs, special events, publications, and meetings. These activities can further the health of all members of a community. The overarching goals of the *Healthy People 2020* initiative are presented in Table 1-1. *Healthy People* boxes related to these goals are integrated throughout this book.

The *Healthy People* initiative is a significant challenge for nursing. Both nursing education programs and clinical nursing practice must respond to major trends in health care. Educational programs for entry-level nurses now place a greater emphasis on health promotion; maintenance; and cost-effective care that responds to the needs of older adults, culturally diverse groups, and underserved populations. Today's nurses must address the identified health problems, developments in health care delivery, research outcomes, and new technologies in order to meet *Healthy People* goals. As a reflection of nursing's contract with society, you are responsible for improving the health status of the public and reducing health disparities. (Health disparities are discussed in Chapter 2.)

Supporting Professional Practice

Professional Nursing Organizations. The American Nurses Association is the primary professional nursing organization. There are numerous professional specialty organizations, such as the American Association of Critical-Care Nurses (AACN), Association of periOperative Registered Nurses (AORN), and Oncology Nursing Society (ONS). Professional organizations have numerous roles in promoting quality patient care and professional nursing practice. These include developing standards of practice and codes of ethics, supporting research, and lobbying for legislation and regulations. Major nursing organizations also promote research into the causes of errors, develop strategies to prevent future errors, and address nursing issues that affect the nurse's ability to deliver patient care safely. Many nurses join a professional organization to keep current in their practice and network with others who are interested in a particular practice area.

QSEN. In 2003 the Institute of Medicine (IOM) commissioned an interdisciplinary task force to study the educational preparation of health care professionals to see whether new graduates were prepared for today's reality of practice.[11] What they found was that all health professions, including nursing, needed to review and revise their curricula and focus on developing specific competencies that serve as a basis for practice. In nursing this is done through a project known as *Quality and Safety Education for Nurses (QSEN) (www.qsen.org)*. QSEN consists of six core competencies: (1) patient-centered care, (2) informatics and technology, (3) evidence-based practice, (4) quality improvement, (5) safety, and (6) teamwork and collaboration. The remainder of this chapter discusses how professional nursing practice is focusing on acquiring the knowledge, skills, and attitudes within each competency.

TABLE 1-1 *HEALTHY PEOPLE 2020*

Overarching Goals

- Attain high quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

PATIENT-CENTERED CARE

Nurses have long demonstrated that they truly deliver patient-centered care based on each patient's unique needs and understanding of the patient's preferences, values, and beliefs. Patient-centered care is interrelated with both quality and safety. In the patient-centered care model, patients and caregivers seek care from competent and knowledgeable health care professionals. Patients and caregivers are involved in making care decisions and managing the patient's care.

Delivery of Nursing Care

Nurses deliver patient-centered care in collaboration with the interdisciplinary health care team and within the framework of a care delivery model. Today a variety of care delivery models are being used in view of nursing shortages, state-mandated nurse-patient ratios, economic issues, and increased acuity of patient conditions.

A *team nursing* model uses a professional nurse as a team leader. As a team leader, you organize and manage the care for a group of patients with other ancillary workers such as licensed practical/vocational nurses (LPN/LVNs) and unlicensed assistive personnel (UAP). In this model, you have the authority and accountability for the quality of care delivered by team members during a work period.

In a *total patient care* model, you assume accountability for the complete care of a patient or group of patients during the assigned shift. In this model, you are responsible for planning and providing all care.

In a *primary nursing* model, you are responsible for a patient or caseload of patients over a period of time.[12] You provide care during assigned shifts, and coordinate and communicate all aspects of patient care with other disciplines and those who provide care when you are absent. Care delivered within a

primary care model strengthens the nurse-patient relationship through a focus on continuity of care and interdisciplinary collaboration.

Continuum of Patient Care

Depending on their health status, patients often move among a multitude of different health care settings. Decisions regarding the most appropriate setting for obtaining health care frequently depend on the cost of care and constraints of a patient's health care insurance plan. Although the hospital remains the mainstay for acute care interventions within this continuum, community-based settings offer patients the opportunity to live or recover in settings that maximize their independence and preserve human dignity. For example, a person may be hospitalized in a trauma unit of an acute care hospital following a motor vehicle crash. After the person is stabilized, he or she may be transferred to a general medical-surgical unit and then to an acute rehabilitation facility. After a period of rehabilitation the person may be discharged to his or her home to continue with outpatient rehabilitation, with follow-up by home health care nurses and care in an outpatient clinic.

The continuum of care does not always include hospitalization. Some patients receive community-based care without experiencing an acute problem requiring hospitalization. Community-based settings where health care is provided include ambulatory care, transitional care, and long-term care. Transitional care settings provide care in between the acute care and the home or long-term care setting (see eTable 1-1 on the website for this chapter). Patients may receive transitional care at an acute rehabilitation facility after head trauma or a spinal cord injury. Long-term care refers to the care of patients for a period greater than 30 days (see eTable 1-2 on the website for this chapter). It may be required for individuals who are severely developmentally disabled, are mentally impaired, or have physical deficits requiring continuous medical or nursing management (e.g., patients who are ventilator dependent or have Alzheimer's disease). Long-term care facilities include skilled nursing facilities, intermediate care facilities, retirement communities, and residential care facilities.

Critical Thinking

Complex health care environments require that you use critical thinking and clinical reasoning skills to make decisions that lead to the best patient outcomes. Although no standard definitions of critical thinking or methods of teaching and evaluating critical thinking have been accepted, critical thinking is recognized as a broad term for a learned skill. **Critical thinking** has been described as knowing how to learn, reason, think creatively, generate ideas, make decisions, and solve problems.[13] Critical thinking is not memorizing a list of facts or the steps of a procedure; instead it is the ability to solve problems by making sense of information. Learning and using critical thinking is a continual process that occurs inside and outside of the clinical setting.

Clinical reasoning is a problem-solving activity in which critical thinking is used to examine patient care issues. It is a process that involves using knowledge from many fields to understand the medical and nursing implications of a patient situation when making decisions regarding patient care.[14] You use clinical reasoning when you identify a change in a patient's status, take into account the context and concerns of the patient and caregiver, and decide what to do about it.

Given the complexity of patient care today, nurses are required to learn and implement critical thinking and clinical reasoning skills long before they gain those skills through the experience of professional practice. Clinical experiences during nursing education provide opportunities for you to learn and make decisions about patient care. To promote practice in critical thinking and clinical reasoning, various education models and techniques have been developed, including exercises in simulation laboratories and interactive scenarios. Throughout this book, select boxes, case studies, and review questions promote your use of critical thinking and clinical reasoning skills.

Nursing Process

Nurses provide patient-centered care using an organizing framework called the nursing process. The **nursing process** is a problem-solving approach to the identification and treatment of patient problems that is the foundation of nursing practice. The nursing process framework provides a structure for the delivery of nursing care and the knowledge, judgments, and actions that nurses use to achieve best patient outcomes. Once started, the nursing process is not only continuous but also cyclic in nature.

The nursing process consists of five phases: assessment, diagnosis, planning, implementation, and evaluation (Fig. 1-3).

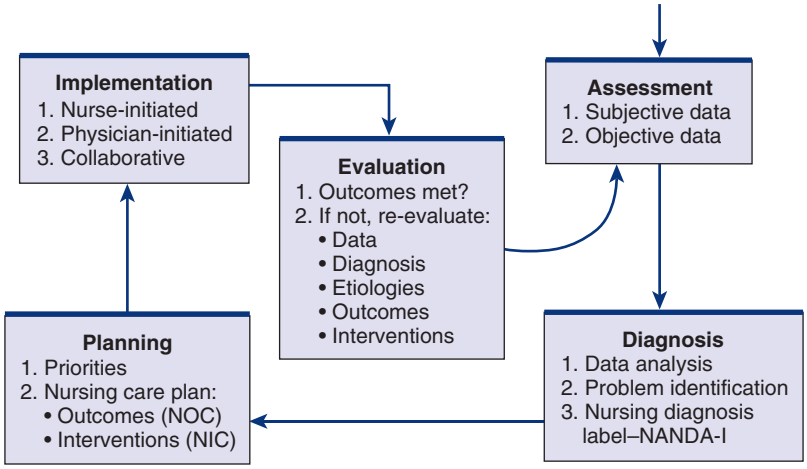

FIG. 1-3 Nursing process.

There is a basic order to the nursing process, beginning with assessment. *Assessment* is the collection of subjective and objective patient information on which to base the plan of care. *Nursing diagnosis* is the act of analyzing the assessment data and making a judgment about the nature of the data. It includes identifying and labeling human responses to actual or potential health problems or life processes. During *planning* the nursing diagnosis directs the development of patient outcomes or goals and identification of nursing interventions to accomplish the outcomes. *Implementation* is the activation of the plan with the use of nursing interventions. *Evaluation* is a continual activity in the nursing process. Evaluation determines whether the patient outcomes have been met as a result of nursing interventions. If the outcomes were not met, a review of the steps of the process is necessary to determine why not. Revision may be needed in assessment (data collection), the nursing diagnosis, planning (determining patient outcomes), or implementation (nursing interventions).

Standardized Nursing Terminologies

The demands of the current health care system challenge the nursing profession to define its practice and its impact on the health and health care of individuals, families, and communities. The nursing profession is asking questions such as the following: What do nurses do? How do they do it? Does it make a measurable difference in the health of those for whom they care? How can nurses best document their care? What happens as a result of their care?

In response to these questions, nursing has moved toward using standardizing nursing terminology (also called *nomenclatures, classification systems,* and *taxonomies*) to clearly define and evaluate nursing care. This can promote continuity of patient care and provide data to support the value of the profession. Instead of using a wide variety of words and methods to describe the same patient problems and nursing interventions, nurses use a readily understood common language to improve communication among themselves. In addition, standardized languages help identify the most effective nursing interventions.[15] For example, do the patient problems of pressure ulcer, decubitus ulcer, and skin breakdown all mean the same thing? What interventions can prevent these problems? Does turning the patient every 2 hours mean the same thing as repositioning the patient every 2 hours? If the patient is turned or repositioned every 2 hours, what happens as a result? How are the results described? Are the results different if a patient is placed on a pressure-relieving mattress or placed on a standard mattress and only turned? How are the results documented, and how do you know what works best?

Standardized terminologies offer ways to organize and describe nursing phenomena. A variety of languages have been developed that address different areas of nursing. Table 1-2 lists the classification systems recognized and approved by the ANA. The Omaha System and the Home Health Care Classification have been developed for community-based and home health care nursing, respectively. The Perioperative Nursing Dataset (discussed in Chapter 19) is used by perioperative nurses. The Nursing Management Minimum Data Set is available for use by nurse managers and administrators.

Three of the nursing terminologies recognized by the ANA are used to describe patient responses, patient outcomes, and nursing interventions: (1) NANDA International: Nursing Diagnoses, Definitions, and Classification; (2) the Nursing Outcomes Classification (NOC); and (3) the Nursing Interventions Classification (NIC). Each of these classification systems focuses on one component of the nursing process. Patients' responses or problems can be labeled using the nursing diagnoses classified and defined by NANDA-I.[16] Nursing interventions, or treatments, can be selected and implemented from NIC,[17] and nursing-sensitive patient outcomes can be identified and evaluated by selecting appropriate NOC outcomes.[18]

TABLE 1-2 ANA-RECOGNIZED NURSING TERMINOLOGIES

- NANDA International Nursing Diagnoses

NANDA-I Nursing Diagnoses. NANDA International (NANDA-I) is a nursing organization that develops a standardized nursing terminology for identifying, defining, and classifying patients' actual or potential responses to health problems.[16] The two main purposes of NANDA-I are to develop a diagnostic classification system or taxonomy and to identify and accept nursing diagnoses. The use of the standardized terminology of nursing diagnoses documents the analysis and synthesis required in making a nursing diagnosis. It verifies nursing's contribution to cost-effective, efficient, quality health care.

The current NANDA-I nursing diagnoses are listed in Appendix B (NANDA-I nursing diagnoses are updated every 2 years). The nursing diagnoses used in this textbook are NANDA-I approved. The NANDA-I list is continually evolving as research results are interpreted and as nurses identify new human responses.

Nursing Outcomes Classification (NOC). Nursing Outcomes Classification (NOC) is a list of concepts, definitions, and measures that describe patient outcomes influenced by nursing interventions. A nursing-sensitive patient outcome is defined as an individual, family, or community state, behavior, or perception that is measured along a continuum in response to a nursing intervention(s).[18] The impact of your nursing practice on patient outcomes can be identified and measured when you choose a NOC outcome. Currently more than 385 coded outcomes have been organized into 7 domains and 34 classes. Each outcome has a label, a definition, a set of specific indicators to be used in rating the outcomes, and a five-point scale for rating the overall outcome and the specific indicators.

Nursing Interventions Classification (NIC). Nursing Interventions Classification (NIC) includes independent and collaborative interventions that you carry out, or direct others to carry out, on behalf of patients. It includes treatments that you perform in all settings and in all specialties. Because each intervention has a coded number, the use of NIC interventions facilitates electronic collection of standardized nursing data to evaluate the effectiveness of the interventions.

TABLE 1-3 EXAMPLE OF NANDA-NOC-NIC LINKAGE

NANDA-I Nursing Diagnosis: *Impaired skin integrity:* A state in which the individual has altered epidermis and/or dermis

NANDA-I–Related Factors	NOC Outcomes	NIC Interventions
Pressure	Tissue integrity: skin and mucous membranes	Pressure management Skin surveillance
Nutritional deficit	Nutritional status: food and fluid intake	Nutrition monitoring Nutrition therapy
Knowledge deficit	Knowledge: illness care	Teaching: disease process

NANDA-I, NANDA International; *NIC,* Nursing Interventions Classification; *NOC,* Nursing Outcomes Classification.

NIC includes more than 500 interventions with a label name, a definition, and a set of activities for you to choose from to carry out the intervention. The interventions are grouped into 7 domains and 30 classes. Although more than 500 interventions may seem overwhelming, you will soon discover those interventions that are used most often in your particular specialty or with your patient population.[17] When planning care for a patient, choose specific interventions from the domain or class that is appropriate for the patient based on the nursing diagnosis and patient outcomes. Each intervention has a list of activities, and you select the appropriate activities from the list to implement the intervention. NIC does not prescribe interventions for specific situations. You are responsible for making the important decision of when and which interventions to use for a specific patient and situation based on your knowledge of the patient and the patient's condition.

NANDA-NOC-NIC Linkages. NANDA, NOC, and NIC (NNN) linkages show how the three distinct nursing terminologies can be connected and used together when planning care for patients. Linkages may assist in determination of a nursing diagnosis, projection of a desired outcome, and selection of interventions to achieve the desired outcome. Because each outcome or intervention has a coded number, the use of NNN facilitates electronic collection of standardized nursing data to evaluate the effectiveness of nursing care. An example of an NNN linkage is found in Table 1-3. The integration of NNN into the nursing process is illustrated in Fig. 1-4.

Nursing Care Plans

The nursing process is usually recorded and documented differently in nursing education when compared to clinical nursing practice. In nursing education the nursing process is frequently recorded in nursing care plans similar to those presented in this textbook. You practice and learn the nursing process by collecting assessment data, identifying nursing diagnoses, and selecting patient outcomes and nursing interventions—all of which are recorded on specific forms. Rationales for the selected interventions are also identified. These nursing care plans are used as teaching and learning tools.

In clinical practice, nursing care plans are often adapted for a specific setting. Electronic and written standardized care plans are used as guides for routine nursing care and are individualized to each patient's unique needs and problems.

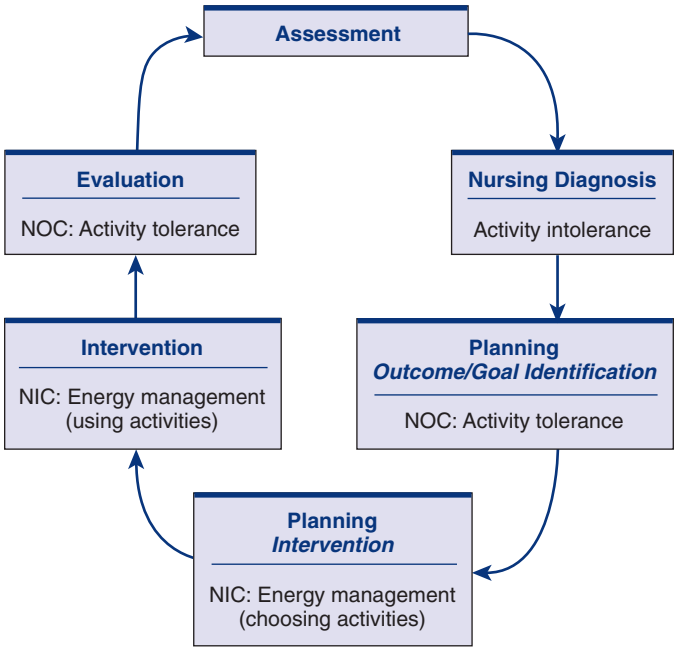

FIG. 1-4 Integration of NANDA, NIC, and NOC into the nursing process.

The nursing care plans presented throughout this book use the NANDA-I–approved nursing diagnoses, listed in order of priority, with NOC outcomes and NIC interventions (NCP 1-1). When any of these care plans are used, they should be individualized for a specific patient. You must use critical thinking to continually evaluate the situation and revise the diagnoses, outcomes, and interventions to fit each patient's unique care needs. All of the nursing care plans for this textbook are available in electronic format on the website at *http://evolve.elsevier.com/Lewis/medsurg*.

Collaborative problems are potential or actual complications of disease or treatment that nurses treat with other health care providers (e.g., physicians, APNs, speech therapists).[19] During the diagnosis phase of the nursing process, you identify these risks for physiologic complications in addition to nursing diagnoses. Identification of collaborative problems requires knowledge of pathophysiology and possible complications of medical treatment. Collaborative problem statements are usually written as "potential complication: _____" or "PC: _____" without a *"related to"* statement. An example is PC: pulmonary embolism. When potential complications are used in this textbook, *"related to"* statements have been added to increase understanding and relate the potential complication to possible causes.

A **concept map** is another method of recording a nursing care plan. In a concept map care plan the nursing process is recorded in a visual diagram of patient problems and interventions that illustrates the relationships among clinical data. Concept mapping is most useful in nursing education to teach nursing process and care planning.

Various formats are used for concept maps, and a variety of shapes, colors, and connecting arrows are used to identify concepts and relationships. In one example, assessment data are used to identify the patient's primary reason for seeking health care. That health state (often a medical diagnosis) is positioned centrally on the map. Positioned around the reason for seeking health care are nursing diagnoses that represent the patient's responses to the health state. Listed with each nursing diagnosis

NURSING CARE PLAN 1-1

*Patient with Heart Failure**

NURSING DIAGNOSIS **Activity intolerance** *related to* imbalance between oxygen supply and demand secondary to cardiac insufficiency and pulmonary congestion *as evidenced by* dyspnea, shortness of breath, weakness, increase in heart rate on exertion, and/or patient's statement, "I am too tired to get out of bed. I have no energy."

PATIENT GOAL Achieves a realistic program of activity that balances physical activity with energy-conserving activities

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Activity Tolerance	***Energy Management***
• Pulse rate with activity _____ • O_2 saturation with activity _____ • Respiratory rate with activity _____ • Systolic BP with activity _____ • Diastolic BP with activity _____ • Ease of breathing with activity _____ • Ease of performing ADLs _____ • Skin color _____	• Encourage alternate rest and activity periods *to reduce cardiac workload and conserve energy.* • Provide calming diversionary activities to promote relaxation *to reduce O_2 consumption and to relieve dyspnea and fatigue.* • Monitor patient's O_2 response (e.g., pulse rate, cardiac rhythm, and respiratory rate) to self-care or nursing activities *to determine level of activity that can be performed.* • Teach patient and caregiver techniques of self-care *that will minimize O_2 consumption* (e.g., self monitoring and pacing techniques for performance of ADLs).
Measurement Scale 1 = Severely compromised 2 = Substantially compromised 3 = Moderately compromised 4 = Mildly compromised 5 = Not compromised	***Activity Therapy*** • Collaborate with occupational and/or physical therapists *to plan and monitor activity and exercise program.* • Determine patient's commitment to increasing frequency and/or range of activities and exercise *to provide patient with obtainable goals.*

ADLs, Activities of daily living; *NIC,* Nursing Interventions Classification; *NOC,* Nursing Outcomes Classification.
*This example presents one nursing diagnosis for heart failure. The complete nursing care plan for heart failure is NCP 35-1 on pp. 780-781.

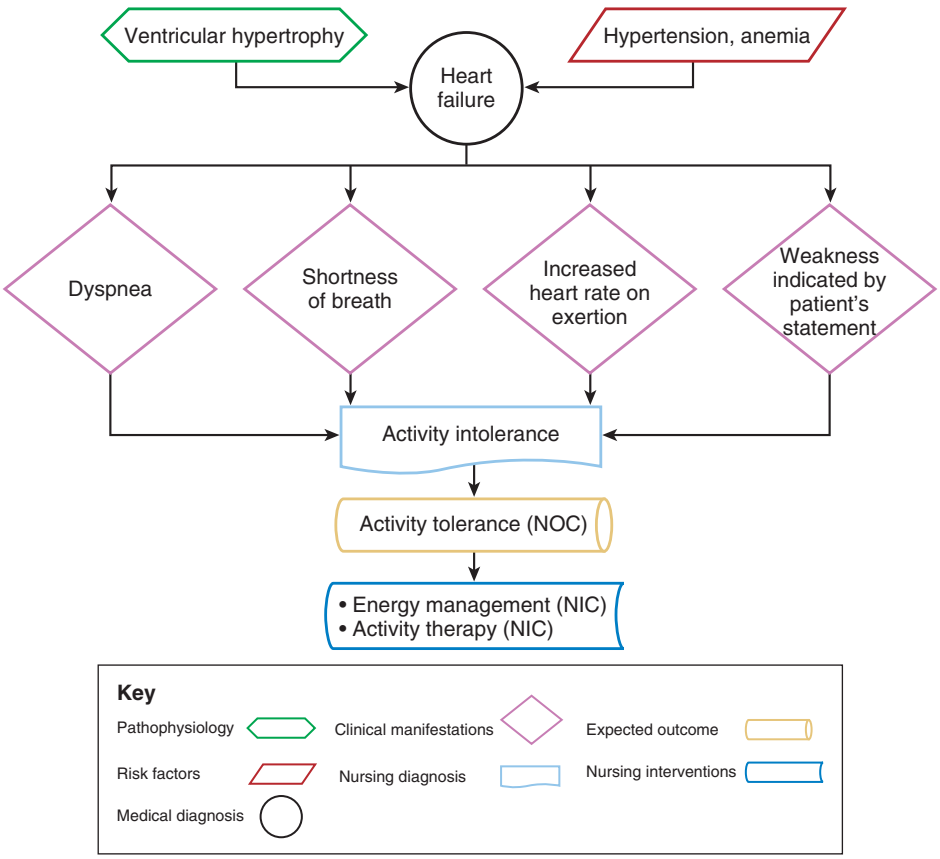

FIG. 1-5 Concept map.

are the assessment data that support the nursing diagnosis. Diagnostic testing data, treatments, medications, and nursing interventions may be listed with the nursing diagnoses or may be identified in separate areas and connected to the nursing diagnoses with arrows.[20] Fig. 1-5 illustrates a simplified version of a concept map for the patient with heart failure. For selected case studies at the end of the management chapters, related concept maps are available on the website at *http://evolve.elsevier.com/Lewis/medsurg*. In addition, a concept map builder is available online on the website.

INFORMATICS AND TECHNOLOGY

Information and Technology in Practice

Nursing is an information-intense profession. Advances in health information technology have changed the way nurses plan, deliver, document, and evaluate care. All nurses, regardless of their setting or role, use informatics and technology every day in practice. The incorporation of technologies into practice has changed how you obtain and review diagnostic information, make clinical decisions, communicate with patients and caregivers, and provide clinical interventions.[21]

Using information technology is becoming increasingly important in providing safe, quality patient care. For example, medication administration applications have been shown to improve patient safety by flagging potential errors, such as look-alike and sound-alike medications and adverse drug interactions, before they can occur. Computerized provider order entry (CPOE) systems can eliminate errors caused by misreading or misinterpreting handwritten instructions. Sensor technology is used to decrease the incidence of falls in high-risk patients.

Being able to use technology skills to communicate and access information is now an essential component of your professional nursing practice. You must be able to use word processing software, communicate by e-mail and text messaging, access the Internet to find information, and follow security and confidentiality rules.[22] You need to demonstrate the skills to safely use patient care technologies and navigate electronic health records and clinical information systems. Throughout this book suggestions on how to use informatics in your practice are highlighted in Informatics in Practice boxes.

Protected health information (PHI) is highly sensitive. The Health Insurance Portability and Accountability Act (HIPAA) is part of federal legislation that addresses the use and disclosure of PHI so that such information is properly protected. With the increased use of informatics and technology come new concerns for how to comply with HIPAA regulations and maintain a patient's privacy. New wireless technologies, increased use of e-mail and computer networking, and the ongoing threat of computer viruses increase the need for properly protecting a patient's privacy.

As a nurse, you have an obligation to ensure the privacy of your patient's health information. To do so, you need to understand your agency's policies regarding the use of technology. You need to know the rules regarding accessing patient records and releasing PHI, know what to do if information is accidently or intentionally released, and diligently protect any passwords you use. If you are using social networking, you must be careful not to place any individually identifiable PHI online.

Clinical Information Systems and Electronic Health Records

A clinical information system (CIS) is a large computerized system that integrates various information technology applications into a centralized repository of information related to patient care.[23] These systems support many types of activities related to patient care, including care documentation, order entry, and the retrieval of results, across various locations. Some examples of CISs including laboratory, nursing, pharmacy, long-term care, and emergency department systems and electronic health records.

An **electronic health record (EHR)** is a computerized record of PHI generated by one or more encounters in any care delivery setting.[24] Information that should be in an EHR includes patient demographics, progress notes, problems, medications, vital signs, past medical history, immunizations, laboratory data, and radiology reports (eFig. 1-1 available on the website for this chapter).

An *electronic medical record (EMR)* is a set of computerized data collected by a health care agency, such as an individual hospital or physician's office, which contributes to a record that is owned and used by that agency. In turn, an EHR is created when information from records created by a variety of agencies under different ownership is made available to other health care providers regardless of the location or affiliation of the health care provider. In practice, the terms *EHR* and *EMR* are often used interchangeably.[25]

The federal government was instrumental in the early adoption of EHRs because of its role in the delivery and payment of health care for millions of Americans through Medicare, the armed services, and the Department of Veterans Affairs (VA). The VA EHR system was one of the first implemented nationwide and today is a prototype for other providers. Patient records in the VA's electronic health system are fully electronic, portable, and readily accessible. The VA's EHR system provides a single place for health care providers to review and update a patient's health record and order medications, special procedures, nursing orders, diets, and diagnostic and laboratory tests. All aspects of a patient's record are integrated, including active problems, allergies, current medications, laboratory results, vital signs, hospitalizations, and outpatient clinic history. The system also provides reminders, cautions, and the ability to review data at sites remote from the original site of data collection.[26]

A national uniform EHR similar to the VA's health record has the potential to reduce medical errors associated with traditional paper records and improve clinical decision making, patient safety, and quality of care. As EHRs, entry systems, laboratories, imaging systems, and pharmacies are all linked into one clinical information network, many types of patient care could be provided anywhere, at anytime, since the "care grid" would always be available.[11] Unfortunately, a number of barriers stand in the way of a national system. EHRs are expensive and technologically complex, requiring a number of resources to implement and maintain. In addition, better communication is needed among the large number of software applications already in use.

Nursing Informatics

Nursing informatics is a specialty that integrates nursing, its information, and information management with information processing and communication technology to support the health of people worldwide.[27] An informatics nurse has a diverse role. Nurse informatacists design and build computer systems that support nurses and other health care providers in all roles and settings to improve decision making and enhance the quality of patient care. Other responsibilities of a nurse informatacist may include training health care providers and implementing, evaluating, and maintaining computer systems.

Computer Languages

When using applications such as an EHR, it is important to use a comprehensive, standardized medical vocabulary. One such

standardized vocabulary is the Systematized Nomenclature of Medicine—Clinical Terms (SNOMED CT). In 2004 the federal government's licensure of SNOMED CT made the vocabulary available, free of charge, to all health care providers through the National Library of Medicine.[28] Uses for SNOMED CT include EHRs, intensive care monitoring, clinical decision support, medical research studies, clinical trials, CPOE, disease surveillance, and consumer health information services.

The use of SNOMED CT is of significant value to nursing in that the vocabulary includes the NANDA-I, NIC, and NOC (NNN) terminologies of nursing. With the use of SNOMED CT, nursing diagnoses, interventions, and outcomes can be recorded using the NNN terminologies. Following the links among diagnosis, interventions, and outcomes will greatly advance evidence-based practice (EBP). For example, when you choose the NANDA-I diagnosis of *fatigue* on a computer, the code 00093 is added to a database. Then you might select the NOC outcome of *endurance,* and the code 0001 would also be added to the database. You could select the NIC interventions of *energy management (0180)* and *exercise promotion (0200),* and these codes would also be incorporated. The coded data can be separated from the patient's name, thus providing for patient anonymity. Links that result from these data can be analyzed and serve not only to improve practice, but also to demonstrate the effectiveness of nursing interventions and formulate nursing research questions. This provides a continuing evaluation of nursing's efficacy.

Today many informatics nurses are concerned that, unless nursing care data are stored electronically, CISs or EHRs will contain no data about the decisions that nurses make. As a result, nursing data will not be used in health care planning and policies. Information about identified nursing problems, independent nursing interventions, and improved patient outcomes will not be apparent, and nursing's role in and contribution to health care will be invisible.[29]

Documenting the nursing process is a critical part of the patient's record. This is important because it provides evidence that nursing practice standards related to the nursing process have been maintained during the care of the patient.

All nurses must work to ensure that nursing data are stored electronically and become part of the EHR. Many different electronic documentation methods and formats are used. However, few agencies have implemented the use of standardized nursing terminologies for documenting nursing care. Using nursing terminologies for documenting nursing practice provides an efficient, consistent way to communicate nursing knowledge. It allows nurses to track, improve, and report on the outcomes of nursing care.[15] If nursing data are to be part of the data analyzed from EHRs, nurses need to decide what data should be included in the EHR and what terminology should be used to record the data so that the meaning is clear, consistent, and valuable.

Telehealth

Increasingly, technology is allowing nurses and other health care providers to deliver patient care services in a wider range of settings. **Telehealth** is the use of videoconferencing or other communication technologies to provide care when patients and health care providers are geographically separated. Telehealth care has many applications, not only in the assessment, diagnosis, and treatment of illness, but also in health promotion, follow-up, and coordination of care. Nurses engaged in telehealth nursing practice continue to assess, plan, intervene, and evaluate the outcomes of nursing care. However, they do so using technologies such as the Internet, computers, telephones, digital assessment tools, and telemonitoring equipment[30] (Fig. 1-6).

FIG. 1-6 Telemonitoring. **A,** Remote blood pressure monitoring. **B,** Videoconference with health care provider.

Home care is seeing significant changes as the result of rapidly expanding remote patient monitoring. A growing number of biomedical devices can collect, monitor, and report patient data in real time. These devices include blood glucose monitors, peak flow meters, scales, stethoscopes, and automated blood pressure cuffs. Video cameras with magnifying capabilities are used to assess wounds and monitor the status of healing. Nurses practicing telehealth can provide patient and caregiver teaching and emotional support through videoconferencing.

EVIDENCE-BASED PRACTICE

Evidence-based practice (EBP) is a problem-solving approach to clinical decision making. It involves the use of the best available evidence (e.g., research findings, data from quality improvement projects, professional organization standards) in combination with clinician expertise and patient preferences and values to achieve desired patient outcomes.[31] The most important reason to use EBP is the delivery of the highest quality of care for the best patient outcomes. Expectations for high-quality, cost-effective care and the increased accessibility of health information have contributed to a need for all health

disciplines to provide care based on the best evidence. Regulatory and accrediting agencies, including The Joint Commission (TJC), require documentation of the effective use of evidence in clinical care decisions.

EBP does not mean that you need to conduct a research study. Instead, EBP is a process that involves finding, appraising, and applying research conducted by others in an effort to answer a specific clinical question. The use of technology supports EBP by providing you with access to data. You can easily search a number of online resources and collect large amounts of clinical information or evidence to identify the best patient care practices.

Steps of EBP Process

The EBP process has seven critical steps (Table 1-4).

Step 0 of EBP. Creating a spirit of inquiry, or an ongoing curiosity about what are the best nursing practices, is important to support the other stages of EBP. Positive patient outcomes depend on you taking an active role in using the best available evidence when delivering care. When you possess a spirit of inquiry, you routinely ask questions about your patient's care and recognize when more information is needed. When your practice is based on valid evidence, you are solving problems and supporting best patient outcomes.[32]

Step 1 of EBP. Step 1 of the EBP process is asking a clinical question in the PICOT format. Formulating the clinical question is the most important step in the EBP process.[33] A well-formulated clinical question that is searchable and answerable creates the context for integrating best available evidence, clinical judgment, and patient preferences. In addition, the question guides the search for the most current literature and the evidence required.

An example of a clinical question in PICOT format is, "In adult cardiac surgery patients (**P** = patients/population) is morphine (**I** = intervention) or fentanyl (**C** = comparison) more effective in reducing pain (**O** = outcome) on the first postoperative day (**T** = time period)?" A properly stated clinical question may not have all components of PICOT in the statement. Some may only include the first four components, PICO without the T, because the (T) timing for the (I) intervention to support the (O) outcome is not always pertinent. The (C) component of PICOT might include a comparison with a specific intervention, the usual standard of care, or no intervention at all.

Step 2 of EBP. Step 2 of the EBP process is a thorough search for and collection of evidence based on the clinical question. The content and type of question direct the clinician to the most appropriate databases. The search begins with the strongest external evidence to answer the question. Preappraised evidence such as systematic reviews and evidence-based clinical practice guidelines are time- and effort-saving resources in the EBP process (see Table 1-4).

Systematic reviews of randomized controlled trials (RCTs) are considered the strongest level of evidence to answer questions about interventions (i.e., cause and effect). Systematic reviews, which include the critical analysis and synthesis of methods and findings from multiple studies, are available for only a limited number of clinical topics and may not suit all types of clinical questions. If the clinical question involves how a patient experiences or copes with a health change, searching for a meta-synthesis of qualitative evidence may be the appropriate approach.

Clinical practice guidelines are helpful for translating research findings into specific interventions. However, these published guidelines vary in comprehensiveness and credibility. Guidelines are produced by a variety of authoring groups such as professional health care societies, patient advocacy organizations, and government agencies.

When insufficient research exists to guide practice, recommendations from expert committees, authority figures, and opinion authorities may be the best evidence available. When care decisions must depend on this type of evidence, ongoing and rigorous outcome data should be collected to provide stronger evidence.

Step 3 of EBP. Step 3 of the EBP process is critically appraising and synthesizing evidence found in the search. The purpose of critical appraisal is to determine the value of the research in actual practice. A successful critical appraisal process focuses on three essential questions: (1) What are the results? (2) Are the results reliable and valid? and (3) Will the results help me in caring for my patients? You must determine the strength of the evidence and synthesize the findings related to the clinical question to conclude what is the best practice.

Step 4 of EBP. Step 4 of the EBP process may differ depending on the strength and breadth of the evidence to answer the question. Recommendations from sufficient, strong evidence such as the meta-analysis of well-designed RCTs can be implemented into practice interventions in combination with clinicians' expertise and patient preferences. For example, although evidence supports the use of morphine as an effective analgesic, it may not be appropriate to use in a patient with renal failure. In another example, although their concerns are not supported by evidence, patients may be worried about perceived addictive effects of morphine and prefer an alternative to opioids for their pain management. These types of decisions must be made by combining knowledge of the best available evidence, clinician judgment, and application if the recommendations to the individual patient's circumstances and preferences.

Many areas in practice do not have an established evidence base or have inconsistent evidence. When evidence is insufficient to guide practice, the fourth step would be to generate data to answer the question. One way for data to be gathered is through the conduct of rigorous research. Health care providers can collaborate with researchers to conduct research and generate knowledge that identifies the best patient care practices.

Step 5 of EBP. Step 5 of the EBP process is evaluation of identified outcomes in the clinical setting. Outcomes to be measured must match the clinical project objective that has been

TABLE 1-4 STEPS OF EVIDENCE-BASED PRACTICE (EBP) PROCESS

0. Cultivate a spirit of inquiry.
1. Ask the burning clinical question using the **PICO** or **PICOT** format:
   Patients/population
   Intervention
   Comparison or comparison group
   Outcome(s)
   Time period (as applicable)
2. Collect the most relevant best evidence.
3. Critically appraise and synthesize the evidence.
4. Integrate all evidence with clinical expertise and patient preferences and values in making a practice decision or change.
5. Evaluate the practice decision or change.
6. Share the outcomes of the decision or change.

implemented. For example, evaluating only the cost of each medication for pain control does not provide data about clinical effectiveness. Outcomes must reflect all aspects of the implementation and capture the interdisciplinary contributions obtained by the EBP process. For example, an EBP initiative related to pain control might involve patients and caregivers, nurses, physicians, pharmacists, physical and respiratory therapists, and other team members. Some outcomes expectations may be shared, whereas other goals may be different for each team member.

Step 6 of EBP. The last step in EBP is to share the outcomes of the EBP change. If you do not share the outcomes of EBP, then other health care providers and patients cannot benefit from what you learned from your experience. Information is shared locally using unit- or hospital-based newsletters and posters and regionally and nationally through journal publications and presentations at conferences.

Implementing EBP

To implement EBP, you must develop the skills to continually seek and then incorporate into practice the scientific evidence that supports best patient outcomes. The incorporation of evidence, balanced with clinical expertise, should take into account the patient's unique circumstances and preferences. EBP closes the gap between research and practice, providing more reliable and predictable care than that based on tradition, opinion, and trial and error. It provides you with an effective process to manage the wealth of information and newly introduced technologies, while balancing concerns about health care costs and an increasing emphasis on quality and patient outcomes.

Throughout this book, two different types of EBP boxes are used to show how EBP is used in nursing practice. The Translating Research into Practice boxes provide initial answers to specific clinical questions. These boxes contain the clinical question, critical appraisal of the supportive evidence, implications for nursing practice, and the source of the evidence. Applying the Evidence boxes provide an opportunity for you to practice your critical thinking skills in applying EBP to patient scenarios.

To assist you in identifying the use of evidence incorporated throughout this book, an asterisk (*) is used in the reference list at the end of each chapter to indicate evidence-based information for clinical practice.

SAFETY AND QUALITY IMPROVEMENT

As the complexity of the environments in which health care is delivered increases, patient safety and communication among health care professionals are affected. In 1999 the IOM issued a report that indicated that at least 44,000 people, and perhaps as many as 98,000 people, die in hospitals each year as a result of preventable medical errors. The report described medical errors as an epidemic and concluded that it was not acceptable for patients to be harmed by a health care system that is supposed to offer healing and comfort.[34]

Since the IOM report, a series of organizations and commissions have provided safety goals for health care organizations and identified a number of safety competencies for health professionals. By implementing various procedures and systems to improve communication and health care delivery to meet safety goals, health care systems are creating a culture of safety that minimizes the risk of harm to the patient. Because you have the greatest amount of interaction with patients, you are a vital part of promoting this culture of safety by providing care in a manner that reduces errors and actively promotes patient safety.

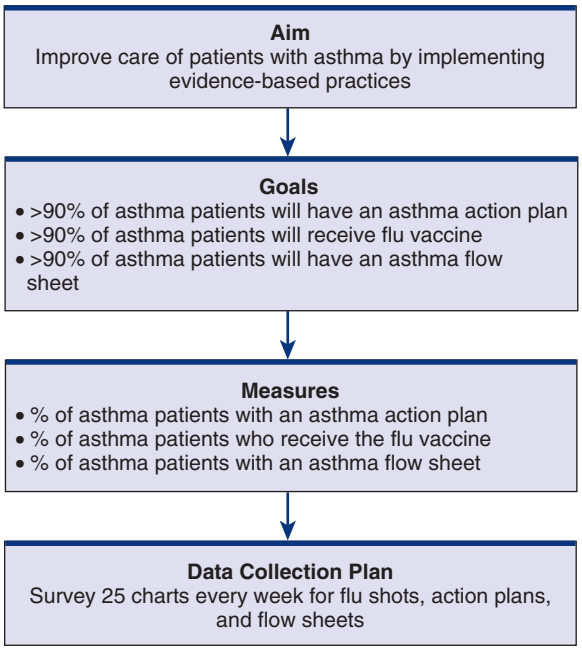

FIG. 1-7 Quality improvement system.

Patient-centered care is interrelated with both quality and safety—the higher the culture of safety, the better the quality of care. Health care systems focused on quality outcomes use practice standards and protocols based on best evidence while considering the patient's unique preferences and needs at the moment. Your role is to coordinate and integrate the complex aspects of patient care, including the care delivered by others, and identify issues that are associated with poor quality and unsafe care.

As part of professional nursing practice, you are responsible for collecting data, using data to monitor patient outcomes, and implementing interventions to improve quality of care. An example of a quality improvement system is shown in Fig. 1-7. You need to be able to assess current practices and compare them with relevant better practices elsewhere as a means of identifying areas for improving care and formulating clinical questions for EBP.

National Patient Safety Goals

The Joint Commission (TJC), the accrediting agency for health care organizations, issues National Patient Safety Goals (NPSGs) for each of its accreditation programs.[35] The NPSGs promote specific improvements in patient safety by providing health care organizations with evidence-based solutions to persistent safety problems. The 2013 goals are listed in Table 1-5. Safety alerts that highlight safety information related to patient care and the NPSGs are integrated throughout the textbook.

TEAMWORK AND COLLABORATION

Interdisciplinary Team Members

To deliver high-quality care, you need to establish effective working relationships with members of the health care team. A

TABLE 1-5 NATIONAL PATIENT SAFETY GOALS*

Safety Goal	Examples
1. Improve the accuracy of patient identification.	• Use at least two ways to identify patients (e.g., have them state full name and date of birth).
2. Improve the effectiveness of communication among caregivers.	• Use SBAR (see Table 1-7) for communication among health care professionals. • Verify telephone or verbal orders by "write down and read back" procedure. • Quickly get important test results to the right staff person.
3. Improve the safety of using medications.	• Label all medicines that are not already labeled. Discard any found unlabeled. • Take extra care with patients who take anticoagulant drugs.
4. Reduce the risk of health care–associated infections.	• Use soap, water, and hand sanitizer before and after every patient contact. • Use evidence-based practices to prevent infections caused by multidrug-resistant organisms.
5. Accurately and completely reconcile medications across the continuum of care.	• Find out what medications each patient is taking. Make certain that it is safe for the patient to take any new medicines with his or her current medicines. • Give a list of the patient's medicines to his or her next caregiver. Give the list to the patient's regular physician before the patient goes home. • Give a list of the patient's medicines to the patient and caregiver before they go home. Explain the list.
6. Reduce the risk of patient harm resulting from falls.	• Evaluate patients for fall risk. • Take action to reduce risk of injury.
7. Prevent health care–related pressure ulcers (decubitus ulcers).	• Assess patients at risk for pressure ulcers on admission and on a regular basis throughout their care.
8. The organization identifies safety risks inherent in its patient population.	• Assess patients at risk for suicide. • Assess any risks for patients who are getting home oxygen therapy, such as fires.
Universal Protocol (UP)	
• Preprocedure verification • Mark procedure site • Performance of time-out	• Conduct a time-out before the start of any invasive or surgical procedure, • Confirm correct patient, procedure, and site.

Adapted from The Joint Commission (TJC): 2013 National patient safety goals, Oakbrook Terrace, Ill. Retrieved from www.jointcommission.org/PatientSafety/NationalPatientSafetyGoals.
*The numbering system is correct and resulted from renumbering by TJC.

health care team may consist of physicians, nurses, pharmacists, occupational and physical therapists, social workers, and others (Table 1-6). As part of your interdisciplinary nursing practice, you will collaborate in many ways by exchanging knowledge, sharing responsibility for problem solving, and making patient care decisions. You may be responsible for coordinating care among the team members and initiating appropriate referrals when you anticipate that expertise in specialized areas is needed to help the patient. To do so, you need to be aware of the knowledge and skills of other team members and be able to communicate effectively among them.

TABLE 1-6 INTERDISCIPLINARY TEAM MEMBERS

Team Member	Description of Services Provided
Dietitian	Provides general nutrition services, including dietary consultation regarding health promotion or specialized diets
Home health aide	Assists patients with their personal care needs, such as bathing, dressing, and hair washing, or with some homemaking activities (e.g., meal preparation or light housekeeping)
Occupational therapist (OT)	May assist patient with fine motor coordination, performance of activities of daily living, cognitive-perceptual skills, sensory testing, and the construction or use of assistive or adaptive equipment
Pastoral care	Offers spiritual support and guidance to patients and caregivers
Pharmacist	Prepares medications and infusion products
Physical therapist (PT)	Works with patients on improving strength and endurance, gait training, transfer training, and developing a patient education program
Physician (medical doctor [MD])	Practices medicine and treats illness and injury by prescribing medication, performing diagnostic tests and evaluations, performing surgery, and providing other medical services and advice
Respiratory therapist	May assist with oxygen therapy in the home, provide specialized respiratory treatments, and instruct patient or caregiver regarding the proper use of respiratory equipment
Social worker	Assists patients with developing coping skills, meeting caregiver concerns, securing adequate financial resources or housing assistance, or making referrals to social service or volunteer agencies
Speech therapist	Focuses on treatment of speech defects and disorders, especially through the use of physical exercises to strengthen muscles used in speech, speech drills, and audiovisual aids that develop new speech habits

Coordinating Care Among Health Care Team Members

Communication. Communication is a key component of facilitating teamwork and care across the care continuum, which is essential for fostering a culture of safety. There is evidence that the majority of patient safety issues result from breakdown in communication.[35] Enhancing communication among the health care team requires a systematic approach. One model used for reporting and hand-off communications is the **SBAR (Situation-Background-Assessment-Recommendation)** technique (Table 1-7). This technique provides a mechanism for framing critical communication about a patient's condition between members of the health care team.[36] Other ways to enhance communication include "time-outs" before surgical procedures or during a busy day on a nursing unit to identify risks and develop a plan for delivering care.

Case Management. **Case management** is a collaborative process that involves assessing, planning, facilitating, and advocating for health services to meet an individual's and/or caregiver's needs through communication and use of available resources to promote cost-effective quality outcomes. Although health care agencies define case management in various ways, the concept of case management involves managing the patient's

TABLE 1-7 GUIDELINES FOR COMMUNICATING USING SBAR

Purpose: SBAR is a model for effective transfer of information by providing a standardized structure for concise factual communications from nurse-to-nurse, nurse-to-physician, or nurse-to–other health professionals.

Steps to Use: Before speaking with a physician or other health care professional about a patient problem, assess the patient yourself, read the most recent physician progress and nursing notes, and have the patient chart available.

S **Situation**	What is the situation you want to discuss? What is happening at the present time? • Identify self, unit. **State:** I am calling about: *patient, room number.* • Briefly state the problem: what it is, when it happened or started, and how severe it is. **State:** I have just assessed the patient and I am concerned about: *identify why you are concerned.*
B **Background**	What is the background or circumstances leading up to the situation? **State** pertinent background information related to the situation that may include • Admitting diagnosis and date of admission • List of current medications, allergies, IV fluids • Most recent vital signs • Date and time of any laboratory testing and results of previous tests for comparison • Synopsis of treatment to date • Code status
A **Assessment**	What do you think the problem is? What is your assessment of the situation? **State** what you think the problem is: • Changes from prior assessments • Patient condition unstable or worsening
R **Recommendation/ Request**	What should we do to correct the problem? What is your recommendation or request? **State** your request. • Specific treatments • Tests needed • Patient needs to be seen now

Source: Kaiser Permanente of Colorado: SBAR technique for communication: a situational briefing model, Institute for Health Care Improvement. Retrieved from *www.ihi.org/knowledge/Pages/Tools/SBARTechniqueforCommunicationASituationalBriefingModel.aspx.*

care across multiple care settings and levels of care.[37] The goals of case management are to provide quality care along a continuum, decrease fragmentation of care across many settings, enhance the patient's quality of life, and contain costs.

A professional nurse often serves as the case manager. The nurse assesses the needs of an individual or caregiver, coordinates services for them, makes referrals as appropriate, and evaluates progress to ensure that short- and long-term goals are met. For example, a patient with severe coronary artery disease may be assigned a nurse as a case manager in an outpatient clinic. When the patient is hospitalized for coronary artery bypass graft surgery, the same case manager coordinates care so that all health care providers understand the patient's unique needs. When the patient is discharged, the case manager determines whether home health care or other services are necessary for the patient.

Clinical Pathways. Care related to common health problems experienced by many patients is delineated and documented using clinical (critical) pathways. A **clinical (critical) pathway** directs the entire health care team in the daily care goals for select health care problems. It includes an interdisciplinary care plan, and goals and interventions specific for each day of hospitalization. The case types selected for clinical pathways are usually those that occur in high volume and are highly predictable, such as myocardial infarction and surgical procedures, including joint replacements, cholecystectomies, and appendectomies.

The clinical pathway describes the patient care required at specific times. An interdisciplinary approach moves the patient toward desired outcomes within an estimated length of stay. The exact content and format of clinical pathways vary among institutions. If clinical pathways are used by an institution, they are usually evidence based and specifically developed by that institution. Nurse- and physician-initiated interventions designed to achieve the patient outcomes are identified throughout the pathway. The interdisciplinary approach can be seen in the referral to and consultation with other health professionals. If a nursing-specific care plan is included in the clinical pathway, it is usually documented with the use of nursing diagnoses and evaluation of patient outcomes. Many pathways are computerized, making them a permanent part of the patient's record.

Delegation and Assignment. As a registered nurse (RN), you will delegate nursing care and supervise others who are qualified to deliver care. **Delegation** is transferring the authority or responsibility to perform a selected nursing task in a selected situation to a competent individual.[38] The delegation and assignment of nursing activities from the professional nurse (the RN) to nonprofessional and/or unlicensed health care personnel is a process that, when used appropriately, can result in safe, effective, and efficient nursing care. Delegating can allow you more time to focus on complex patient care needs.

Delegation typically involves tasks and procedures that **unlicensed assistive personnel (UAP)** and licensed practical/vocational nurses (LPN/LVNs) perform. Nursing interventions that require independent nursing knowledge, skill, or judgment such as assessment, patient teaching, and evaluation of care are your responsibility and cannot be delegated. UAP are unlicensed individuals who assist the RN, the professional nurse. UAP may include nursing aides, orderlies, nursing assistants, attendants, or technicians. Professional nurses are responsible for supervising the education, training, and use of UAP in providing direct patient care. As a nurse, you use professional judgment to determine appropriate activities to delegate based on the patient's needs, the UAP's education and training, and extent of supervision required.[38] In addition, some state boards of nursing identify specific activities that may be delegated to UAP such as obtaining routine vital signs on stable patients, feeding and assisting patients at mealtimes, ambulating stable patients, and helping patients with bathing and hygiene. eFig. 1-2 (available on the website for this chapter) shows a decision tree for delegation to UAP.

Delegation may also involve the LPN/LVN, whose scope and standards of practice are defined by the state nursing practice act and regulated by state agencies. However, you may also delegate specific tasks to the LPN/LVN. You must know the legal scope of practical/vocational nursing practice and delegate and assign nursing functions appropriately. In most states, LPN/LVNs may administer medications, perform sterile

TABLE 1-8 FIVE RIGHTS OF NURSING DELEGATION

1. The *right* task
2. Under the *right* circumstances
3. To the *right* person
4. With the *right* direction and communication
5. Under the *right* supervision and evaluation

procedures, and provide a wide variety of interventions planned by the RN.

Assignment is different from delegation in that assignment is the distribution of work that each staff member is responsible for during a given work period. Therefore the term *assign* is used when you direct a person to do something that he or she is authorized to do. Assignments occur when an RN directs other RNs, LPN/LVNs, or UAP to perform care that is within their scope of practice. Whether you delegate or are working with staff to which you assign tasks, you are responsible for the patient's total care during your work period. You are responsible for the supervision of the UAP or LPN/LVN and remain accountable for ensuring that the delegated tasks are completed in a competent manner. This supervision includes guidance and direction, oversight, evaluation, and follow-up by the RN.[38]

Delegation is a skill that is learned and must be practiced for you to be proficient in managing patient care. You need to use critical thinking and professional judgment to ensure that the Five Rights of Nursing Delegation are implemented (Table 1-8). This book presents delegation decisions in boxes in appropriate chapters and provides delegation questions in case studies at the end of the management chapters.

DELEGATION DECISIONS

Delegation Decisions Boxes Throughout Book

Title	Chapter	Page
Assessment and Data Collection	3	38
Blood Transfusions	31	676
Cardiac Catheterization and Percutaneous Coronary Intervention (PCI)	34	758
Caring for the Incontinent Patient	46	1091
Caring for the Patient Receiving Bladder Irrigation	55	1320
Caring for the Patient Requiring Mechanical Ventilation	66	1625
Caring for the Patient With an Acute Stroke	58	1405
Caring for the Patient With Alzheimer's Disease	60	1455
Caring for the Patient With a Cast or Traction	63	1514
Caring for the Patient With Chronic Venous Insufficiency	38	858
Caring for the Patient With Diabetes Mellitus	49	1185
Caring for the Patient With Hypertension	33	724
Caring for the Patient With Neutropenia	31	661
Caring for the Patient With a Seizure Disorder	59	1426
Caring for the Patient With Venous Thromboembolism (VTE)	38	855
Corrective Lenses and Hearing Aids	22	411
Intravenous Therapy	17	309
Nasogastric and Gastric Tubes and Enteral Feedings	40	900
Ostomy Care	43	994
Oxygen Administration	29	592
Pain	9	134
Postoperative Patient	20	354
Skin Care	24	446
Suctioning and Tracheostomy Care	27	518
Urinary Catheters	46	1093
Wound Care	12	183

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. An example of a nursing activity that reflects the American Nurses Association's definition of nursing is
   - **a.** diagnosing a patient with a feeding tube as being at risk for aspiration.
   - **b.** establishing protocols for treating patients in the emergency department.
   - **c.** providing antianxiety drugs for a patient who has disturbed sleep patterns.
   - **d.** identifying and treating dysrhythmias that occur in a patient in the coronary care unit.
2. A nurse working on the medical-surgical unit at an urban hospital would like to become certified in a medical-surgical specialty. The nurse knows that this process would most likely require
   - **a.** a bachelor's degree in nursing.
   - **b.** formal education in advanced nursing practice.
   - **c.** experience for a specific period in medical-surgical nursing.
   - **d.** membership in a medical-surgical nursing specialty organization.
3. A nurse is providing care to a patient after right hip surgery. Within a pay-for-performance system, a critical role of the nurse is to
   - **a.** ensure that care is provided using a minimal amount of supplies.
   - **b.** discharge the patient at completion of the number of approved days of care.
   - **c.** implement measures to decrease the risk of the patient acquiring an infection.
   - **d.** assess the patient's ability to pay for health care services at the time of admission.
4. The nurse is assigned to care for a newly admitted patient. Number in order the steps for using the nursing process to prioritize care. (Number 1 is the first step, and number 5 is the last step.)
   - ___ Evaluate whether the plan was effective.
   - ___ Identify any health problems.
   - ___ Collect patient information.
   - ___ Carry out the plan.
   - ___ Determine a plan of action.

5. The linkages among NANDA-I nursing diagnoses, NOC patient outcomes, and NIC nursing interventions can be used to
   a. evaluate patient outcomes.
   b. provide guides for planning care.
   c. predict the results of nursing care.
   d. shorten written care plans for individual patients.
6. Advantages of the use of informatics in health care delivery are *(select all that apply)*
   a. reduced need for home care nurses in rural areas.
   b. increased patient anonymity and confidentiality.
   c. the ability to achieve and maintain high standards of care.
   d. improved communication of the patient's health status to the health care team.
   e. access to standardized plans of care that are available for most types of health problems.
7. When using evidence-based practice, the nurse
   a. must use clinical practice guidelines developed by national health agencies.
   b. should use findings from randomized controlled trials to plan care for all patient problems.
   c. uses clinical decision making and judgment to determine what evidence is appropriate for a specific clinical situation.
   d. statistically analyzes the relationship of nursing interventions to patient outcomes to establish evidence for the most appropriate patient interventions.
8. The nurse's role in addressing the National Patient Safety Goals established by The Joint Commission includes *(select all that apply)*
   a. using side rails and alarm systems as necessary to prevent patient falls.
   b. memorizing and implementing all the rules published by The Joint Commission.
   c. verifying telephone and verbal orders using the "write down and read back" procedure.
   d. encouraging patients to be actively involved in and question their own health care.
   e. obtaining a complete list of the patient's medications and monitoring their use throughout the continuum of care.
9. The nurse is caring for a diabetic patient in the ambulatory surgical unit who has just undergone debridement of an infected toe. Which task is most appropriate for the nurse to delegate to unlicensed assistive personnel (UAP)?
   a. Check the patient's vital signs.
   b. Evaluate the patient's awareness.
   c. Monitor the site of the patient's IV catheter.
   d. Evaluate the patient's tibial and pedal pulses.

1. a, 2. c, 3. c, 4. 5, 2, 1, 4, 3, 5. b, 6. c, d, e, 7. c, 8. a, c, e, 9. a.

LEARNING OUTCOMES

1. Identify the key determinants of health and equity.
2. Describe the primary factors that contribute to health disparities and health equity.
3. Define the terms *culture, values, acculturation, ethnicity, race, stereotyping, ethnocentrism, cultural imposition, transcultural nursing, cultural competency, folk healer,* and *culture-bound syndrome.*
4. Explain how culture and ethnicity may affect a person's physical and psychologic health.
5. Describe strategies for successfully communicating with a person who speaks a language that you do not understand.
6. Apply strategies for incorporating cultural information in the nursing process when providing care for patients from different cultural and ethnic groups.
7. Describe the role of nursing in reducing health disparities.
8. Examine ways that your own cultural background may influence nursing care when working with patients from different cultural and ethnic groups.

transcultural nursing, p. 24

This chapter addresses health disparities and cultural issues. Nursing has a key role in recognizing and reducing health disparities and providing culturally competent care.

DETERMINANTS OF HEALTH

Why are there differences in the health status of people in America? How do these differences occur? The **determinants of health** are factors that (1) influence the health of individuals and groups (Fig. 2-1) and (2) help explain why some people experience poorer health than others.[1] Where people are born, grow up, live, work, and age helps determine their health status, behaviors, and care.

Health status describes the health of a person or a community. Many measures make up the concept of health status. For individuals, this means the sum of their current health problems plus their coping resources (e.g., family, financial resources). For a community, health status is the combination of health measures for all individuals living in the community. Community health measures include birth and death rates, life expectancy, access to care, and morbidity and mortality rates related to disease and injury.

Reviewed by Michelle M. Byrne, RN, PhD, CNE, CNOR, Professor of Nursing, North Georgia College & State University, Dahlonega, Georgia; Doreen Mingo, RN, MSN, Assistant Professor, Coordinator, Office of Diversity Services, Nursing Workforce Diversity Grant Project Director, Allen College, Waterloo, Illinois; and Kathleen M. Barta, RN, EdD, Associate Professor, University of Arkansas, Eleanor Mann School of Nursing, Fayetteville, Arkansas.

Factors in a person's social and physical environment, including personal relationships, workplace, housing, transportation, and neighborhood violence, all contribute to health status.[1] For example, the risk of youth homicide is much higher in neighborhoods with gang activity and high crime rates. The physical environment in which one lives, works, and plays may expose a person to such risks as environmental hazards (workplace injuries), toxic agents (chemical spills, industrial pollution), unsafe traffic patterns (lack of sidewalks), or absence of fresh and healthy food choices.

An individual's behavior is influenced by his or her environment, education, and economic status. Behaviors such as tobacco and illicit drug use are strongly linked to a number of health conditions (e.g., lung cancer, liver disease). An individual's biologic makeup such as genetics and family history of disease (e.g., heart disease) can increase the risk for specific diseases.

The amount and quality of health care available also contribute to an individual's health. For example, in some states, health care organizations have reduced the number of Medicaid patients they will cover. Although the use of emergency departments (EDs) for health care is increasing, they are not usually set up to provide primary or long-term follow-up care. In addition, the number of EDs, particularly in rural areas, is decreasing.[2] These determinants of health can either improve a person's health status or put an individual at risk for disease, injury, and mental illness.

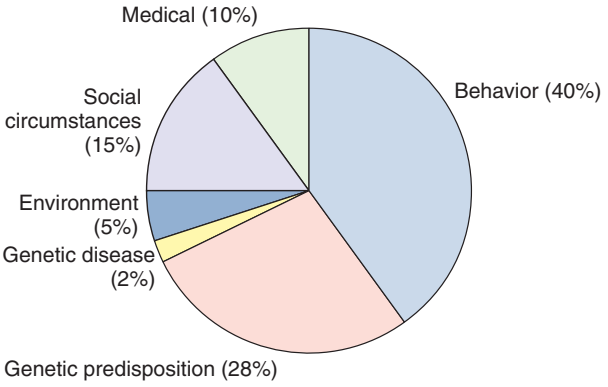

FIG. 2-1 Determinants of health.

HEALTHY PEOPLE

Access to Health Services

- Increase the proportion of people
  - With health insurance.
  - With a usual primary care provider.
  - Who receive appropriate evidence-based clinical preventive services.
- Increase the proportion of insured people with coverage for clinical preventive services.
- Ensure that all people have access to rapidly responding, prehospital emergency medical services.
- Reduce the proportion of individuals who are unable to obtain or delay in obtaining necessary medical care, dental care, or prescription medicines.
- Decrease the time people
  - Spend waiting in physicians' offices and emergency departments.
  - Wait between identifying a need for specific tests and treatments and actually receiving those services.

The vision of the government's *Healthy People 2020* is to create a society in which all people live long, healthy lives (see Table 1-1). This report (discussed in Chapter 1 on p. 5) includes measures that can be used to reflect the health status of the U.S. population.[3]

HEALTH DISPARITIES AND HEALTH EQUITY

Health disparities are differences in the incidence, prevalence, mortality rate, and burden of diseases that exist among specific population groups in the United States because of social, economic, or environmental disadvantages. Health disparities can affect population groups based on gender, age, ethnicity, socioeconomic status, geography, sexual orientation, disability, or special health care needs.[4,5] **Health equity** is achieved when every person has the opportunity to attain his or her health potential and no one is disadvantaged.

Factors and Conditions Leading to Health Disparities

Many factors and conditions can lead to the development of health disparities (Table 2-1). Awareness of these factors will assist you in providing optimal care for your patients.

ETHICAL/LEGAL DILEMMAS

Health Disparities

Situation

E.M., a 47-year-old Mexican American woman with type 2 diabetes mellitus, comes to the clinic to have her blood glucose measured. It has been 12 months since her last visit. At that time the nurse requested that she bring along her glucometer and strips to demonstrate how she checks her blood glucose because her glucose values were high at her previous visits.

When you check E.M.'s equipment and glucose strips, it is clear that the strips are for a different machine and they expired more than 2 years ago. When you inquire about the situation, E.M. explains that she cannot afford to come to the clinic or to buy new equipment and supplies to check her blood glucose level. During the day E.M. cares for her three grandchildren so her daughter can work. E.M. spends most of her income on food for her family, so little money is left over for her own health care.

Ethical/Legal Points for Consideration

- Ethnic minorities and other vulnerable or disadvantaged groups experience certain chronic illnesses at higher rates. Limited access to high-quality, accessible, and affordable health care services is clearly associated with an increased incidence of illness and complications, as well as a reduced life span.
- People with certain health problems such as diabetes may have difficulty obtaining health care insurance. These issues must be considered in the broader context of social justice.
- In many states the legal definition of the role of the professional nurse includes patient advocacy. Advocacy includes the obligation to provide adequate follow-up care for all patients, especially those who are experiencing health care disparities.
- When disparities are observed in an individual patient and family, as a nurse you must consider the possibilities of discrimination and abuse. Professional nurses are legally and ethically responsible for patient advocacy. When failure to fulfill this obligation results in harm to the patient, the nurse may incur legal liability.

Discussion Questions

1. How would you work with E.M. to help her obtain the necessary resources and knowledge to care for her diabetes?
2. What can you do to begin working on the problems of health disparities in your community?

TABLE 2-1 FACTORS AND CONDITIONS LEADING TO HEALTH DISPARITIES

- Ethnicity and race
- Place

- Education
- Occupation or unemployment
- Health literacy
- Gender
- Age
- Sexual orientation
- Disability status
- Health care provider attitudes
- Lack of health care services access
- Language barrier

Ethnicity and Race. The terms **ethnicity** and **race** are subjective and based on self-report. These terms are used interchangeably in conversation and cannot be defined by genetic markers. Social context and lived experiences influence people's decision about the ethnic and race category to which they belong. For example, ethnic and race categories may differ on a person's birth and death certificates.

People are asked to identify their own ethnicity and race for the purpose of health data collection (e.g., for birth and death certificates). Collection of health data based on self-reported ethnic and race categories is important for research, to inform policy, and to understand and eliminate disparities. For example, federal agencies are required to list a minimum of two ethnicities for people who self-identify as either *Hispanic or Latino* and *Not Hispanic or Latino.* A Hispanic or Latino is typically a person of Cuban, Mexican, Puerto Rican, South or Central American, or other Spanish descent, regardless of race.

In addition, federal agencies are required to list a minimum of five race categories: white, black or African American, American Indian or Alaska Native, Asian, and Native Hawaiian or other Pacific Islander.[6] People are asked to identify their race using one or more categories. In this book the terms *ethnicity* and *race* are used interchangeably or together.

Despite dramatic improvements in treatments to prolong life and improve quality of life for most individuals, racial and ethnic minorities have benefited far less from these advances. Disparities are generally determined by comparing population groups. Currently in the United States, based on the latest census, racial and ethnic minority groups include Hispanics/Latinos 16.3%, African Americans 12.6%, Asian Americans 4.8%, Native Hawaiians and other Pacific Islanders 0.2%, Native Americans and Native Alaskans 0.9%, and two or more races 2.9% of the U.S. population.[7] The percentages for most of these groups are expected to increase in the coming decades.

Obesity and chronic illness rates for diabetes, hypertension, chronic obstructive pulmonary diseases, cancer, and stroke are higher among minority people. Racial, ethnic, and cultural differences exist in health services, treatments provided, and access to health care providers. For example, African American men are less likely to be offered intervention procedures for cardiovascular disease and stroke.[8,9] African American and Hispanic women are less likely to have mammography for breast cancer screening.[6] Differences in access to screening and treatment exist even when minority groups are insured at the same level as whites. When patient groups are given the same care, the treatment outcomes are similar across racial and ethnic groups.[8,9]

Disease risk and outcomes are also influenced by race and ethnicity. For example, compared with U.S. white and African American populations, Native Americans have a higher incidence of stroke and are more likely to die as a consequence.[9]

Breast and cervical cancer mortality rates are higher in Hispanic and African American women than in other American women.[10-12] African Americans are three times more likely to die from heart disease compared with whites. Fortunately, numerous strategies are underway to promote health equity and reduce disparities.

Place and Health. **Place** refers to the geographic and environmental location where a person is born, grows, lives, works, and ages. Place affects the use of health services, health status, and health behaviors.

Approximately 25% of Americans live in nonurban or rural areas.[7] Three percent of Americans live in designated frontier counties. Differences in access to health care services among frontier, rural, and urban settings can create geographic health disparities. For example, rural populations and Native Americans living on reservations may need to travel long distances to receive health care. This can result in inadequate or less frequent access to health care services. Some parts of the rural United States are considered "medically underserved" because of decreased numbers of health care providers per population.

People living in rural areas have higher rates of cancer, heart disease, diabetes, depression, and injury-related deaths than people living in urban areas. For example, in rural Appalachia the rates of lung, colon, cervical, and rectal cancer are higher than the national average.[13] Rural populations tend to be older than urban populations. Many rural areas have higher rates of obesity and chronic disease. Rural Americans are less likely to work for employers who provide health insurance.[12,13] As a group, rural populations have lower literacy rates and poorer health behaviors (e.g., increased smoking rates, increased substance abuse, higher rates of obesity, lower rates of physical

activity). Generally, smaller and more isolated rural communities with low economic resources experience greater difficulties accessing high-quality health care.

Living in urban centers may also predispose a person to health disparities. Concerns about personal safety (e.g., clinics located in high-crime neighborhoods) can make patients reluctant to visit health care providers. At the same time, health care providers such as home health nurses working in high-risk areas may experience distress when they witness crime, drug use, or other illegal activities.[14] Among the most obvious health behaviors affected by place are physical activity and nutrition. Safe, walkable neighborhoods with playgrounds and sources of healthy foods promote physical activity and healthy eating. Social support and networks are related to health and coping with illness. Social networks are more likely to be found in communities where neighbors interact and rely on one another. Place may have more influence on the incidence of hypertension, diabetes, and obesity for women than race or ethnicity.[15]

Income, Education, and Occupation. People of lower income, education, or occupational status experience worse health. In addition, they die at a younger age than those who are more affluent. In fact, adults without a high school diploma or equivalent are three times more likely to die before age 65 than those with a college degree.[16] Health care costs are one of the important factors that contribute to health disparities. Individuals who have no insurance, are underinsured, or lack financial resources to pay for treatment of diseases may forgo health care visits and treatments (Fig. 2-2). Patients who lack the knowledge to apply for government assistance programs (e.g., Medicaid) are also at risk. The number of uninsured Americans has increased over the past decade.[17] Hazardous work environments and high-risk occupations of laborers also increase health risk and contribute to higher rates of illness, injury, and death.

Health literacy is defined as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions. This includes the ability to read, comprehend, and analyze information; understand instructions; weigh risks and benefits; and ultimately make decisions and take action. Approximately 80 million Americans have limited healthy literacy.[16,18] Low health literacy is associated with more hospitalizations, greater use of emergency department care, decreased use of cancer screening and influenza vaccine, decreased ability to use medications correctly, and higher mortality rates among older adults. On a daily basis, patients need to self-manage conditions such as diabetes and asthma. For example, patients with diabetes may not be able to maintain adequate blood glucose levels if they cannot read or understand the numbers on the home glucose monitoring system. The inability to read and understand medication labels can result in taking medications at the wrong time or in the wrong dose. Health literacy is discussed further in Chapter 4.

Gender. Health disparities exist between men and women. Adult women use health care services more than men. At the same time, women are less likely than men to have medical insurance. Women may not receive the same quality of care (Fig. 2-3). For example, women are less likely than men to receive procedures (e.g., coronary angiography) for cardiovascular disease.[19] When gender is combined with racial and ethnic differences, the disparities are even greater. (Gender Differences boxes are presented throughout this book that highlight gender differences in disease risk, manifestations, and treatment.)

Age. Older adults are at risk for experiencing health disparities in the number of diagnostic tests performed and aggressiveness of treatments used. Biases toward older adults that affect their care, or *ageism,* are discussed in Chapter 5. Older women are less likely to be offered mammograms. Older people of low socioeconomic status experience greater disability, more limitations in activities of daily living, and more frequent and rapid cognitive decline.[20] Older adults who belong to minority groups are less likely than their white counterparts to receive screening for prostate and colorectal cancer.[21]

Sexual Orientation. Sexuality is defined as a person's romantic, emotional, or sexual attraction to another person. Gay, lesbian, and bisexual orientation places an individual at risk for health disparities due to their social, economic, or environmental disadvantages. With the repeal of the military's "don't ask, don't tell" legislation in 2010, the focus on the rights and specific health care needs of lesbian, gay, bisexual, and transgender (LGBT) individuals has increased.

Lesbian women are more likely to be obese when compared with their heterosexual counterparts. Lesbian and bisexual

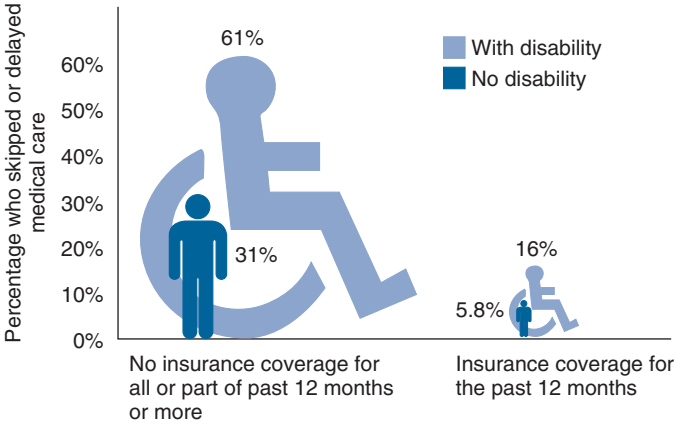

FIG. 2-2 Percentage of adults ages 18 to 64 years old who skipped or delayed medical care because of cost. The data are displayed by disability and insurance coverage status.

FIG. 2-3 Older Asian women are especially at risk for health disparities. (iStockphoto/Thinkstock)

women have increased risk factors for cardiovascular disease.[22] Gay men have higher rates of human immunodeficiency virus and hepatitis infections than other groups. Gay men and lesbian women have higher smoking rates than heterosexuals.

Understanding the cause of these disparities among LGBT individuals is essential to providing safe and high-quality care. One of the barriers to accessing high-quality health care by LGBT adults is the current lack of providers who are knowledgeable about their health needs. LGBT patients may also experience fear of discrimination in health care settings.[23] Within many, but not all, health care settings, LGBT health care issues are now more visible. The Joint Commission requires that patients be allowed the presence of the support individual of their choice. In addition, hospitals need to adopt policies that bar discrimination based on factors such as sexual orientation and gender identification and expression. *Healthy People 2020* has added an objective on LGBT health *(www.healthypeople.gov/2020/topicsobjectives2020/overview.aspx?topicid=25*).

Health Care Provider Attitudes. Certain behaviors and biases of the health care provider can contribute to health disparities. Factors such as bias and prejudice can affect health care–seeking behavior in minority populations.[24] The health care system itself may also contribute to the problem of health disparities. For example, a clinic located in an area with a large Vietnamese immigrant population that does not provide translators or educational materials and financial forms in Vietnamese may limit these families' ability to understand how to access health care.

Discrimination and *bias* based on a patient's race, ethnicity, gender, age, sexual orientation, or ability to pay are likely to result in less aggressive or negative treatment practices. Sometimes discrimination is difficult to identify, especially when it occurs at the institutional level. Because a health care provider's overt discriminatory behavior may not be immediately evident to the patient or yourself, it may be difficult to confront. Even well-intentioned providers who try to eliminate bias in their care can demonstrate their prior beliefs or prejudices through nonverbal communication. Many policies are in place to eliminate discrimination, but it still exists.[25]

CULTURE

Culture is a way of life for a group of people. It includes the behaviors, beliefs, values, traditions, and symbols that the group accepts, generally without thinking about them. This way of life is passed along by communication and imitation from one generation to the next. You can also think of culture as cultivated behavior that is acquired through social learning. It is the totality of a person's learned, accumulated experience that is socially transmitted. The four classic characteristics of culture are described in Table 2-2.

Values are the sets of rules by which individuals, families, groups, and communities live. They are the principles and standards that serve as the basis for beliefs, attitudes, and behaviors. Although all cultures have values, the types and expressions of those values differ from one culture to another. These cultural values develop over time, guide decision making and actions, and may affect a person's self-esteem. Cultural values are often unconsciously developed early in life as a child learns about acceptable and unacceptable behaviors. The extent to which a person's cultural values are internalized influences that person's tendency toward judging other cultures, while usually using his or her own culture as the accepted standard. Table 2-3 provides some examples of cultural characteristics of different ethnic groups in the United States.

Although individuals within a cultural group have many similarities through their shared values, beliefs, and practices, there is also diversity within groups (Fig. 2-4). Each person is culturally unique. Such diversity may result from different perspectives and interpretations of situations. These differences may be based on age, gender, marital status, family structure, income, education level, religious views, and life experiences. Within any cultural group, there are smaller groups that may not hold all of the values of the dominant culture. These smaller cultural groups have experiences that differ from those of the dominant group. These differences may be related to ethnic background, residence, religion, occupation, health, age, gender,

TABLE 2-2 BASIC CHARACTERISTICS OF CULTURE

- *Dynamic* and ever-changing
- *Not always shared* by all members of a cultural group
- *Adapted* to specific conditions such as environmental factors
- *Learned* through oral and written histories, as well as socialization

TABLE 2-3 DISTINCT CULTURAL CHARACTERISTICS OF DIFFERENT ETHNIC GROUPS IN THE UNITED STATES

Native American
- Folk healing
- Living in harmony with people and nature
- Respect for all things living
- Returning what is taken from nature
- Doing the honorable thing
- Respect for tribal elders and children
- Spiritual guidance

Hispanic/Latino
- Cultural foods
- Folk healing
- Extended family valued
- Involvement of family in social activities
- Religion and spirituality highly valued
- Respect for elders and authority
- Interdependence and collectivism

African American
- Cultural foods
- Family networks
- Folk healing
- Importance of religion
- Interdependence within ethnic group
- Music and physical activities valued

European American
- Individualistic and competitive
- Equal rights of genders
- Independence and freedom
- Materialistic
- Self-reliance valued
- Technology dependent
- Youth and beauty valued

Asian American
- Cultural foods
- Folk healing
- Respect for one's parents and ancestors
- Family loyalty
- Respect for elders
- Harmonious relationships
- Harmony and balance within body vital for preservation of life energy

Pacific Islander American
- Kinship alliance among nuclear and extended family
- Natural order and balanced relationships
- Collective concern and involvement
- Knowledge is collective; belongs to group, not individual

Adapted from Andrews MM, Boyle JS: *Transcultural concepts in nursing care,* ed 5, Philadelphia, 2008, Wolters Kluwer-Lippincott Williams & Wilkins; and Giger JN, Davidhizar RE: *Transcultural nursing: assessment and intervention,* ed 6, St Louis, 2012, Mosby.

FIG. 2-4 Members of this family share a common heritage. (Jupiterimages/Photos.com/Thinkstock)

education, or other factors that unite the group. Members of a subculture share certain aspects of culture that are different from those of the overall cultural group. For example, among Hispanics, some seek professional health care immediately when symptoms appear, other Hispanics rely first on folk healers, and yet other Hispanics first seek the opinion of family and friends before seeking formal health care.

Cultural beliefs about symptom tolerance and health care–seeking behavior can contribute to health disparities. Some cultures consider pain something to be endured or ignored, and as a result, the patient does not seek help. Some cultures may view diseases or problems fatalistically; that is, people see no reason to seek treatment because they believe it is unlikely to have any benefit. Some cultures view the signs and symptoms of an illness as "God's will" or as a punishment for some prior behavior.[26]

Fatalism is higher in individuals with lower socioeconomic status. Fatalistic beliefs are associated with reduced cancer prevention activities such as exercising, not smoking, and following a healthy diet.[27] In some cultures it may not be acceptable to see a health care provider who is not of the same gender or ethnic group. Such beliefs can result in delays in seeking health care or inadequate treatment.

Acculturation is the life-long process of incorporating cultural aspects of the contexts in which a person grows, lives, works, and ages.[28,29] Acculturation is often bidirectional. In other words, the context also changes as it is influenced by a person's culture. Change may be in attitudes, behaviors, and values. For example, a sedentary person who loves to cook may change his or her attitude toward exercise when living with athletic roommates, who in turn also change as they begin to appreciate cooking. Behaviors change when an immigrant child learns the local language while also influencing the conduct of classmates. Lastly, a deeply held value such as self-sufficiency may change for a person exposed to a culture where reliance on others dominates.

Newcomers may adopt both the strengths and the limitations of the dominant culture. This is relevant when considering health behaviors of individuals and the quality of health care delivered by professionals. For example, an immigrant may be negatively influenced by a dominant cultural context in which unhealthy eating habits prevail. As a new nurse, you may be negatively or positively influenced by the culture of care that is most prevalent in the workplace.[30]

The result of acculturation for the individual may be new cultural variations in attitudes, behaviors, and values. All people participate in this process over their lives. People who move to a new cultural context are more aware of the acculturation experience than people who are not exposed to new experiences. Exposure to new cultural contexts increases the cultural competency of nurses.

Stereotyping refers to an over-generalized viewpoint that members of a specific culture, race, or ethnic group are alike and share the same values and beliefs. This oversimplified approach does not take into account the individual differences that exist within a culture. Being a member of a particular cultural, ethnic, or racial group does not make the person an expert on other members of that same group. Such stereotyping can lead to false assumptions and affect a patient's care. For example, it would be inappropriate for you to assume that just because a nurse is Mexican American, he would know how a Mexican American patient's beliefs might affect that patient's health care practices. A young nurse born and raised in a large city has experienced a different culture than the older patient who was born and raised in a rural area of Mexico.

Ethnocentrism refers to the belief that one's own culture and worldview are superior to those of others from different cultural, ethnic, or racial backgrounds.[31] Comparing others' ways to your own can lead to seeing others as different or inferior. Health care providers' ethnocentrism can result in poor communication, patient alienation, and potentially inadequate treatment. To avoid ethnocentrism, you need to remain open to a variety of perspectives and maintain a nonjudgmental view of the values, beliefs, and practices of others. Failure to do this can result in ethnic stereotyping or cultural imposition.

Cultural imposition occurs when one's own cultural beliefs and practices are imposed on another person or group of people. In health care it can result in disregarding or trivializing a patient's health care beliefs or practices. Cultural imposition may happen when a health care provider is unaware of the patient's cultural beliefs and plans and implements care without taking them into account.

Cultural safety describes care and advocacy that prevent cultural imposition. Culturally safe practice requires cultural competency and action to ensure that cultural histories, experiences, and traditions of patients, their families, and communities are valued and shape health care approaches and policies.[29,31]

The term **transcultural nursing** was coined by Madeleine Leininger in the 1950s. Transcultural nursing is a specialty that focuses on the comparative study and analysis of cultures and subcultures. The goal of transcultural nursing is the discovery of culturally relevant facts that can guide the nurse in providing culturally appropriate care.[31]

CULTURAL COMPETENCE

Cultural competence is the ability to understand, appreciate, and work with individuals from cultures other than your own. It involves an awareness and acceptance of cultural differences, self-awareness, knowledge of the patient's culture, and adaptation of skills to meet the patient's needs. The four components of cultural competence are (1) cultural awareness, (2) cultural

knowledge, (3) cultural skill, and (4) cultural encounter[31] (Table 2-4).

Specific information is presented throughout this book to assist you in developing an awareness of cultural differences and learning assessment skills for different cultural groups. Table 2-7 (later in this chapter) presents a cultural assessment guide. Review cultural characteristics associated with a group when preparing to interview a patient. However, it is essential to seek information from patients about their culture because they may not exhibit the typical cultural characteristics.

Providing culturally competent care increases patient satisfaction, reduces health disparities, increases patient safety, and prevents misunderstandings between you and your patients. It also involves integrating cultural practices into Western medicine. For example, before some diagnostic procedures and interventions, it is typical to have patients remove personal objects that are worn on the body. Ask patients whether they wear personal objects and the significance of their removal, since they may have cultural or spiritual significance. You also need to know whether wearing these objects will compromise patient safety, test results, or outcomes of the intervention.

TABLE 2-4 HOW TO DEVELOP CULTURAL COMPETENCE

Description	Role of Nurse
Cultural Awareness	
• Ability to understand patients' unique cultural needs	• Identify your own cultural background, values, and beliefs, especially as related to health and health care. • Examine your own cultural biases toward people whose cultures differ from your own culture.
Cultural Knowledge	
• Process of learning key aspects of a group's culture, especially as it relates to health and health care practices • Patients as the best source of information about their culture	• Learn basic general information about predominant cultural groups in your geographic area. Cultural pocket guides can be a good resource. • Assess patients for presence or absence of cultural traits based on an understanding of generalizations about a cultural group. • Do not make assumptions based on cultural background because the degree of acculturation varies among individuals. • Read research studies that describe cultural differences. • Read ethnic newspaper articles and books. • View documentaries about cultural groups.
Cultural Skill	
• Ability to collect relevant cultural data • Performance of a cultural assessment	• Be alert for unexpected responses with patients, especially as related to cultural issues. • Become aware of cultural differences in predominant ethnic groups. • Develop assessment skills to do a competent cultural assessment for any patient.* • Learn assessment skills for different cultural groups, including cultural beliefs and practices.
Cultural Encounter	
• Direct cross-cultural interactions between people from culturally diverse backgrounds • Extended contact with a cultural group to enhance understanding of its values and beliefs	• Create opportunities to interact with predominant cultural groups. • Attend cultural events, such as religious ceremonies, significant life passage rituals, social events, and demonstrations of cultural practices. • Visit markets and restaurants in ethnic neighborhoods. • Explore ethnic neighborhoods, listen to different types of ethnic music, and learn games of various ethnic groups. • Visit or volunteer at health fairs in local ethnic neighborhoods. • Learn about prominent cultural beliefs and practices, and incorporate this knowledge into planning nursing care.

*See Table 2-7 later in the chapter.

CULTURAL DIVERSITY IN THE HEALTH CARE WORKPLACE

Poorer health outcomes for minorities are linked to the shortage of culturally and ethnically diverse health care providers, who have historically been underrepresented in the health professions.[32] A diversity gap exists between the ethnic composition of the health care workforce and the overall population in the United States (Fig. 2-5). The diversity of nurses in the United States is increasing but still lags behind that of the population. African Americans, Hispanic/Latino Americans, and Native Americans make up more than 27% of the population but only 17% of the nation's nurses.

Cultural differences exist in how well patients believe they can communicate with their health care provider. Communication issues include not understanding the health care provider, feeling that they are not listened to, and having questions but not asking them. In the United States approximately 25% to 33% of minority patients have difficulty communicating with their health care provider, compared with 16% of white patients. Similarly, minority patients are less likely than whites to have a regular health care provider. African Americans are more likely to receive outpatient care in the emergency department (ED) and have fewer physician visits.[33]

When health care providers from different cultures work together as members of the health care team, opportunities for miscommunication and conflict can occur. This is termed *cultural conflict.* The cultural origins of miscommunication and

FIG. 2-5 Nurses working together in a multicultural health care environment. (Fuse/Thinkstock)

conflict in the workplace are often interconnected with cultural beliefs, values, and etiquette. Seeking clarification about misperceptions and misunderstandings is a communication strategy to foster effective teamwork among a multicultural health care team. To ensure the recruitment and retention of nurses from minority populations, all members of the health care team and leadership must create an environment that promotes effective cross-cultural communication and reduces bias and discrimination.

CULTURAL FACTORS AFFECTING HEALTH AND HEALTH CARE

Many cultural factors affect the patient's health and health care. Several potential factors are presented in Table 2-5.

Folk Healers

Many cultures have **folk healers,** who are also known as *traditional healers.* Most folk healers speak the person's native language and cost less than conventional health care providers. Among the many folk healers found worldwide, Hispanics may turn to a *curandero* (or *curandera*), African Americans may visit a *hougan,* Native Americans may seek help from a medicine man or *shaman,* and Asian Americans may use the services of a Chinese herbal therapist. In addition to folk healers, some cultures involve lay midwives (e.g., *parteras* for Hispanic women) in the care of pregnant women.

Folk medicine is a form of prevention and treatment that is culturally based and traditionally relies on oral transmission of healing techniques from one generation to the next. The patient may not use the term *folk medicine* but thinks of these as cultural home remedies or treatment practices. Folk medicine may be practiced in the home without the guidance of a folk healer. It is important to assess whether the patient is practicing traditional or folk healing.

Spirituality and Religion

Spirituality and religion are aspects of culture that may affect a person's beliefs about health, illness, and end-of-life care. They may also play a role in nutrition and decisions related to health, wellness, and how to respond to or treat an illness.

Spirituality refers to a person's effort to find purpose and meaning in life. It is influenced by a person's unique life experiences and reflects one's personal understanding of life's mysteries. Spirituality relates to the soul or spirit more than to the body, and it may provide hope and strength for an individual during an illness.

Religion is a more formal and organized system of beliefs, including belief in or worship of God or gods. Religious beliefs include the cause, nature, and purpose of the universe and involve prayer and rituals. Religion is based on beliefs about life, death, good, and evil. You can use several interventions to meet a patient's religious and spiritual needs, including prayer, scripture reading, listening, and referral to a chaplain, rabbi, or priest.[34]

Many patients find that rituals help them during times of illness. Rituals help a person make sense of life experiences and may take the form of prayer, meditation, or other rituals that the patient may create. With appropriate training, you may

TABLE 2-5 CULTURAL FACTORS AFFECTING HEALTH AND HEALTH CARE

Time Orientation
- For some cultures it is more important to attend to a social role than to arrive on time for an appointment with a health care provider.
- Some cultures are future oriented; others are past or present oriented.

Language and Communication
- Patients may not speak English and may not be able to communicate with the health care provider.
- Even with interpreters, communication may be difficult.

Economic Factors
- Patients may not get health care because they cannot pay for it or because of the costs associated with travel for health care.
- Refugee or undocumented immigrant status may deter some patients from using the health care system.
- Immigrant women who are heads of households or single mothers may not seek health care for themselves because of child care costs.
- Patients may lack health insurance.

Health Care System
- Patients may not make or keep appointments because of the time lag between the onset of an illness and an available appointment.
- Hours of operation of health care facilities may not accommodate patients' need to work or use public transportation.
- Requirements to access some types of care may discourage some patients from taking the steps to qualify for health care or health care payment assistance.
- Some patients have a general distrust of health care professionals and health care systems.
- Lack of ethnic-specific health care programs may deter some individuals from seeking health care.
- Transportation may be a problem for patients who have to travel long distances for health care.
- Adequate interpreter services may be unavailable.
- Patients may not have a primary health care provider and may use emergency departments or urgent care centers for health care.
- Shortages of health care providers from specific ethnic groups may deter some people from seeking health care.
- Patients may lack knowledge about the availability of existing health care resources.
- Facility policies may not be culturally competent (e.g., hospital policy may limit the number of visitors, which is problematic for cultures that value having many family members present).

Beliefs and Practices
- Care provided in established health care programs may not be perceived as culturally relevant.
- Religious reasons, beliefs, or practices may affect a person's decision to seek (or not seek) health care.
- Patients may delay seeking health care because of fear or dependence on folk medicine and herbal remedies.
- Patients may stop treatment or discontinue visits for health care because the symptoms are no longer present, and they believe that further care is not required.
- Some patients associate hospitals and extended care facilities with death.
- The patient may have had a previous negative experience with culturally incompetent health care providers or discriminatory practices.
- Some people mistrust the majority population and institutions dominated by them.
- Some patients may feel apprehensive about unfamiliar diagnostic procedures and treatment options.

include spiritual questions in the complete assessment of the patient and plan care based accordingly. (Table 10-5 has a spiritual assessment guide that may be used with patients.) Table 2-6 summarizes health-related beliefs and practices of selected religious groups.

Cross-Cultural Communication

Communication refers to an organized, patterned system of behavior that may be verbal or nonverbal (Fig. 2-6). *Verbal communication* includes not only one's language or dialect, but also voice tone, volume, timing, and ability to share thoughts and feelings. More than 45 million people in the United States speak a language other than English in their home, with Spanish being the most common. Hispanics who do not speak English at home are less likely to receive a variety of health care services regardless of whether they are comfortable speaking English.[35]

Nonverbal communication may take the form of writing, gestures, body movements, posture, and facial expressions. Nonverbal communication also includes eye contact, use of touch, body language, style of greeting, and spatial distancing. Eye

FIG. 2-6 Co-workers from different cultures communicate with verbal and nonverbal cues. (BananaStock/Thinkstock)

TABLE 2-6 HEALTH-RELATED BELIEFS AND PRACTICES OF SELECTED RELIGIOUS GROUPS

Amish
- Alcoholic beverages and drugs are prohibited unless prescribed by health care professional.
- Abortion, artificial insemination, and stem cell use are prohibited.
- Amish seldom purchase commercial health insurance.

Catholicism
- Many fast and abstain from meat and meat products on Ash Wednesday and the Fridays of Lent.
- Artificial contraception and direct abortion are prohibited. Indirect abortion (e.g., treatment of uterine cancer in a pregnant woman) may be morally justified.
- Sacrament of the Sick includes anointing of sick with oil, blessing by a priest, and communion (unleavened wafer made of flour and water).

Church of Jesus Christ of Latter-Day Saints (Mormons)
- Strict dietary code called Word of Wisdom prohibits all alcoholic beverages, hot drinks (nonherbal teas and coffee), tobacco, and illegal or recreational drugs.
- Fasting for 24-hour period occurs monthly on "Fast Sunday."
- During hospitalization or serious illness, an elder anoints the ill person with oil while a second elder seals the anointing with a prayer and blessing (laying on of hands).
- Abortion is prohibited except when the mother's life is in danger.

Hinduism
- Eating meat is prohibited because it involves harming a living creature.
- Cremation is most common form of body disposal, but fetuses or newborns are sometimes buried.

Islam
- Fasting during daytime hours occurs during a month-long period called Ramadan.
- Ritual cleansing with water before eating and before prayer is practiced.
- Eating pork or taking medicines with pork derivatives is prohibited.
- Drinking alcoholic beverages is prohibited.
- Artificial insemination is permissible only if from the husband to his own wife.

Jehovah's Witness
- Transfusions of blood in any form or agents in which blood is an ingredient are not acceptable. Blood volume expanders are acceptable if they are not derivatives of blood.
- Transplants that involve bodily mutilation are prohibited.
- Therapeutic and on-demand abortions are prohibited.
- Artificial insemination is prohibited for both donors and recipients.

Judaism
- Strictly observant Jews never eat pork, shellfish, or predatory fowl and never mix milk dishes and meat dishes in preparing foods. Fish with fins and scales are permissible.
- Certain foods and drink are designated as kosher, which means "proper." All animals must be ritually slaughtered.
- On the eighth day after birth, boys are circumcised in a ritual called Brit Milah, and girls are given a dedication ceremony involving prayers and blessings.
- Abortion is morally unacceptable except when the mother's life is in danger.
- Organized support system for the sick includes a visit from the rabbi. The rabbi may pray with the sick person alone or in a minyan, a group of 10 adults over age 13.
- If an autopsy is performed, all body parts must be returned for burial.

Seventh-Day Adventism
- Vegetarian diet encouraged.
- Nonvegetarian members refrain from eating foods derived from any animal having a cloven hoof that chews its cud (e.g., pigs, goats). Eating fish with fins and scales is acceptable, but consuming shellfish is prohibited.
- Consumption of alcoholic beverages is prohibited.
- Fasting is practiced and involves abstaining from food or liquids by healthy members of the church.

Buddhism*
- Consumption of alcoholic beverages and illicit drugs is prohibited.
- Moderation in diet and avoidance of extremes are practiced.
- Central tenets are maintaining right views, intentions, speech, actions, livelihood, effort, mindfulness, and concentration.

*Data from Andrews MM: Religion, culture, and nursing. In MM Andrews, JS Boyle, editors: *Transcultural concepts in nursing care,* ed 6, Philadelphia, 2012, Lippincott Williams & Wilkins.

contact varies greatly among cultural groups. Patients who are Asian, Arab, or Native American may avoid direct eye contact and consider it disrespectful or aggressive. Hispanic patients may expect you to look directly at them, but may not return that direct gaze. Other variables to consider include the role of gender, age, acculturation, status, or position on what is considered appropriate eye contact. For example, Muslim-Arab women exhibit modesty when avoiding eye contact with men other than their husbands and when in public situations.

Silence has many meanings, and it is important to understand the meaning of silence for different cultural groups. Some people are comfortable with silence, whereas others become uncomfortable and may speak to decrease the silent times. It is important to clarify what silence means in an interaction with a patient. Patients sometimes nod their head or say "yes" as if agreeing with you or to indicate they understand. Actually, they may be doing this because it is a culturally acceptable manner of showing respect, not because they understand or agree.

Many Native Americans are comfortable with silence and interpret silence as essential for thinking and carefully considering a response. In these interactions, silence shows respect for the other person and demonstrates the importance of the remarks. In traditional Japanese and Chinese cultures, the speaker may stop talking and leave a period of silence for the listener to think about what has been said before continuing. Silence may be intended to show respect for the speaker's privacy, whereas in some cultures (e.g., French, Spanish, Russian) the person may interpret silence as meaning agreement. Asian Americans may use silence to demonstrate respect for elders, whereas African Americans may use silence as a response to what is perceived to be an inappropriate question.

Family Roles and Relationships

Family roles differ from one culture to another (Fig. 2-7). It is important for you to determine who should be involved in communication and decision making related to health care. Some cultural groups emphasize interdependence rather than independence. In the United States many in the mainstream culture have strong beliefs related to autonomy. An individual is expected to sign consent forms when receiving health care. In other cultural groups a family member may be expected to make health care decisions. When you encounter a family that values interdependence over independence, the health care system may have difficulty adapting to how decisions are made. Treatment may need to be delayed while the patient waits for significant family members to arrive before giving consent for a procedure or treatment. In other instances the patient may make a decision that is best for the family despite adverse outcomes for the patient. Being aware of such values will better prepare you to advocate for the patient.

FIG. 2-7 Family roles and relationships differ from one culture to another. (Jack Hollingsworth/Photodisc/Thinkstock)

Some cultural differences relate to expectations of family members in providing care. In some cultures, family members expect to provide care for the patient even in the hospital. The patient may expect that the family, along with the health care providers, will provide all care. This view is the opposite of the predominant Western expectation that the patient will assume self-care as quickly as possible.

Ask about culturally relevant gender relationships. For example, in some cultures, such as many Arab groups, it is not appropriate for a man to be alone with a woman other than his wife. Nor is it appropriate for a woman other than a man's wife to provide physical care for him. The clinical implication of this cultural belief is that for many patients from Arab cultures, nurses cannot provide direct physical care for patients of the opposite gender. In some instances, procedures or treatments may be carried out for patients from the opposite gender but only if a third party is present.

Personal Space

Personal space zones refer to the preferred distances between two individuals. Personal space distances vary from culture to culture, as well as within a culture. For European Americans in the United States, the *intimate distance* ranges from 0 to 18 inches, and the *personal distance* ranges from 18 inches to 4 feet. The personal distance is the one experienced with friends. Social distance ranges from 4 to 12 feet, and public distance is 12 feet or more.[36] As a nurse, you often interact with patients in the intimate or personal zones, which might be uncomfortable for the patient.

Cultural groups have wide variations in their perception of appropriate distances. Whereas an American nurse of European descent may be comfortable with a certain distance, a person from a Hispanic or Middle Eastern background may believe that the distance is too far and will move closer, perhaps causing you to feel uncomfortable. If you then move away to a more comfortable distance, this may cause the other person to think that you are unfriendly, or the person may be offended. Personal space distance also varies within cultures.

Touch

Physical contact with patients conveys various meanings depending on the culture. To do a comprehensive assessment, touching a patient is necessary. Many people of Asian and Hispanic heritage believe that touching a person's head is a sign of disrespect, especially because the head is believed to be the source of one's strength and/or soul. Numerous people in the world believe in the evil eye, or *mal ojo.* In one culture-bound syndrome the illness, usually in a child or a woman, is believed to result from excessive admiration by another person. In some cultures the proper way to ward off the evil eye is to touch the area of admiration. For example, if the person admires the hair, the top of the head may be touched. It is important for you to ask permission before touching anyone, particularly if it is necessary to touch the person's head.

Nutrition

An important part of cultural practices is food, including both the foods that are eaten and rituals and practices associated with food. Muslims fast during the daytime during the Islamic month of Ramadan. Such practices may affect when and how medications are taken. Patients may be asked to make major changes in their diets because of health problems, or alternatively food may be used to cope with life changes such as homesickness. Specific foods may be considered essential to good health during pregnancy or other life stages. It is important that the health care provider take into account food-related cultural beliefs, practices, and habits when discussing nutrition with patients and planning their diets.

When individuals and families immigrate to an area that is very different from their country of origin, they may experience unfamiliar foods, food-storage systems, and food-buying habits. They also may come from countries that have limited food supplies because of poverty, wars, and poor sanitation. They may arrive with conditions such as general poor nutrition, hypertension, diarrhea, and dental caries. Other problems may develop after the person arrives in the new country. For example, second-generation Hispanic immigrants have a greater chance of becoming overweight than their first-generation counterparts. The increase in weight is related to the degree of acculturation experienced by the immigrant.[37]

Immigrants and Immigration

Migration is driven by a number of conditions, such as overcrowding, natural disasters, geopolitical conflict, persecution, and economic forces. Because of these migrations, a rich diversity of cultures exists in many communities and countries today (Fig. 2-8).

Recent immigrants may be at risk for physical and mental health problems for many reasons. Conditions in their countries of origin (e.g., malnutrition, poor sanitation, civil war) may have resulted in chronic health problems. In addition, recent immigrants are at increased risk for health problems after arriving in a new area. Relocation is associated with many losses and can cause economic hardship, physical stress, and mental distress.

As new immigrants go through the acculturation process, many experience cultural stress as they adjust to their new environment, especially if they have left relatives behind or are unable to return to their home country. Older immigrants are especially affected by changes in role and social position. This may result in depression. Posttraumatic stress disorder is seen in immigrants who have survived wars and violence. Immigrants may face barriers to social acceptance, such as prejudice or discrimination, and experience a lack of ethnic and cultural resources. For some, it may mean loss of the social status that they experienced in their countries of origin.

FIG. 2-8 Recently arrived immigrants join a neighbor for a barbecue, a common American tradition. (Jack Hollingsworth/Photodisc/Thinkstock)

Another potential problem is tuberculosis (TB). More than half of the TB cases in the United States occur in individuals born outside the country. Individuals who have recently immigrated from areas that have a high endemic rate of TB are more likely to have TB.[38] Foreign-born Hispanics and Asians combined account for 48% of the nation's TB cases. The top five countries of origin of foreign-born people with TB were Mexico, Philippines, Vietnam, India, and China. The *Refugee Health Guidelines* from the Centers for Disease Control and Prevention supports early identification and treatment.[39]

During the past 40 years, the migration pattern of North America has shifted. Whereas once most immigrants came from Europe, now most immigrants originate from Asia, Latin America, and Africa. Additionally, an increased number of first- and second-generation immigrants enter the United States after visiting friends and relatives. These individuals have a higher risk for malaria, typhoid fever, cholera, and hepatitis A than native-born Americans. Many immigrants lack health insurance and may primarily obtain their health care in emergency departments and urgent care clinics. Therefore nurses in all settings need to be aware of refugee health screening, treatment recommendations, and resources for access to health care.

Medications

Genetic differences among people from diverse ethnic or racial groups may explain differences in medication selection, dosage, or administration. For example, some medicines are more effective in certain ethnic groups than others. Side effects may vary among individuals from diverse backgrounds. eTable 2-1 on the website for this chapter highlights some ethnic differences in reaction to medications.

Genetic variations can affect how the body processes a drug and the overall effect of selected drugs on the body. Although race and ethnicity are imprecise indicators of genetic differences, they can be helpful in anticipating variations in the response to medications. (Genetics and drug metabolism are discussed in Chapter 13.)

Regardless of their cultural origins, many people use both cultural remedies and prescription drugs to treat their illnesses. Problems can result from interactions of these substances. For example, Chinese Americans who take ginseng as a stimulant and an antihypertensive drug may suffer adverse effects. Some Mexican Americans may treat gastrointestinal problems with preparations that contain lead. Individuals may self-treat their depression with St. John's wort, which can result in adverse effects if prescription antidepressants are also taken.

Patients may avoid standard Western medicine until herbal and other remedies become ineffective or the illness becomes acute. The challenge for you is to try to accommodate the patient's desire for traditional aspects of care while also using evidence-based approaches as appropriate and as acceptable to the patient. Evaluate the safety and appropriateness of the patient's traditional cultural healing therapies.

Develop a collaborative, trusting relationship with patients and encourage them to discuss their traditional approaches to healing. Seek out information on potential drug and herbal product interaction from the pharmacist. Honor the patient's choices, if safe and effective, since this will enhance collaboration and may have a positive impact on health outcomes.

Psychologic Factors

Symptoms are interpreted through a person's cultural norms and may vary from the recognized interpretations of Western medicine. All symptoms have meaning, and the meanings may vary from one culture to another. It is important to ask patients what their illness means to them, what they believe is the cause, and what they think is the best treatment (Table 2-7).

Culture-bound syndromes are illnesses or afflictions that are recognized only within a cultural group (Table 2-8). The symptoms, course of the illness, and people's reactions to the illness are limited to specific cultures. Culture-bound syndromes are expressed through psychologic or physical symptoms.

TABLE 2-7 CULTURAL ASSESSMENT*

A cultural assessment should include the following:

- Brief history of the cultural group with which person identifies
- Values orientation
- Cultural sanctions and restrictions
- Communication
- Health-related beliefs and practices
- Nutrition
- Socioeconomic considerations
- Organizations providing cultural support
- Educational background
- Religious affiliation
- Spiritual considerations

Adapted from Jarvis C: *Physical examination and health assessment*, ed 6, Philadelphia, 2012, Saunders.
*A comprehensive cultural assessment guide is available (eTable 2-2) on the website for this chapter.

NURSING MANAGEMENT
REDUCING HEALTH DISPARITIES AND INCREASING CULTURAL COMPETENCY

NURSE'S SELF-ASSESSMENT

The first step in reducing health disparities and providing culturally competent care is for you to assess your own cultural background, values, and beliefs, especially those that are related to health and health care. Many tools are available to assist you with this process (*http://nccc.georgetown.edu*).

Table 2-4 suggests ways for you to improve your cultural competence. This information can help you better understand patients and provide culturally competent care. It is important to understand that cultures evolve and change over time. Culturally competent care requires continual learning and self-reflection.[40] Many other important aspects of culture related to

TABLE 2-8 CULTURE-BOUND SYNDROMES

Syndrome	Description
Hispanics/Latinos	
Bilis* or *colera	Caused by strong anger or rage. Many Hispanic/Latino groups believe that anger affects the body balance of hot and cold. Symptoms include acute nervous tension, headache, trembling, screaming, stomach disturbances, and, in severe cases, loss of consciousness.
Ataque de nervios	Brought on by a stressful family event (e.g., death, divorce). Symptoms may include uncontrollable shouting, crying and trembling, and verbal or physical aggression.
Empacho	Condition described as food forming into a ball that clings to the stomach or intestines, causing pain and cramping.
Susto	Sometimes referred to as "fright sickness" or "soul loss." A traumatic anxiety-depressive state that may result from a frightening experience, such as a loud sound or some threat. Can cause anxiety, insomnia, listlessness, loss of appetite, and social withdrawal. One treatment is to have the affected person lie on the floor. The healer then sweeps indigenous herbs over the person's body while praying to release the evil wind.
Native Americans	
Ghost sickness	Condition sometimes associated with witchcraft and a preoccupation with death. Symptoms include general weakness, loss of appetite, a feeling of suffocation, recurring nightmares, and a pervasive feeling of terror.
Chinese	
Shenjing shuairuo	Characterized by physical and mental fatigue, headaches and other pains, dizziness, sleep disturbances, and concentration difficulties.
European Americans (Appalachians)	
States of blood	Blood can exist in four states that are arranged into two sets of extremes: high and low blood, and thick and thin blood. The healthy person has blood that is balanced among these four states. A person with an imbalance lacks vitality; symptoms are fatigue, dizziness, pale complexion, and listlessness.
African Americans	
Brain fag	Term describing brain "fatigue" caused by the challenges of school. Symptoms include difficulties concentrating, remembering, and thinking.
Thin blood	Affects older adults, women, and children. Generally weakens an individual and increases susceptibility to illness.
Caribbean and Southern United States	
Falling out	Characterized by a sudden collapse, which may sometimes be preceded by dizziness or "swimming" in the head. The person can hear but is unable to move.
Cambodians	
Koucharang* or *Kit chroeun	Translates as "thinking too much," brought about by having witnessed or experienced a horrific trauma. Characterized by physical and emotional exhaustion, immobilization, and constant preoccupation with past suffering and loss.
Koreans	
Hwa-byung	Ailment characterized by resentment that is brought about by bitterness and discontent.

health care are included in the Culturally Competent Care sections throughout this book.

In today's increasingly multicultural environment, you will meet patients, families, significant others, and members of the health care team from many different cultures. You will find yourself in patient care situations that require an understanding of the patient's cultural beliefs and practices. Even when you provide care for patients from your own cultural background, you may be from a different subculture than the patient. For example, there are more than 550 federally recognized Native American tribes in the United States, so it would be inappropriate for you to assume that a Native American nurse can give culturally appropriate care to a Native American patient when both may be from different tribes. A white nurse from an urban upbringing may find cultural differences with a white patient from a rural community.

PATIENT ASSESSMENT

Health care providers play an important role in reducing health disparities. However, the causes of health disparities are not always easy to identify. Assess patients for their risk for reduced health care services because of limited access, inadequate resources, age, or low health literacy.

A cultural assessment should be included in the nursing process. Table 2-7 lists important components of the assessment. A comprehensive cultural assessment guide is available in eTable 2-2, which is available on the website for this chapter. Determine (1) the patient's health beliefs and health care practices; and (2) the patient's perspective of the meaning, cause, and preferred treatment of illness.[41] Ask questions that you are comfortable with based on your own culture.

How can you be aware of the differences among ethnic groups? Using guides to cultural assessment will facilitate the nursing process when working with patients, families, or other groups who are from different cultures. Although guides can assist in this process, you need to be careful not to stereotype or assume that common cultural characteristics pertain to each individual patient. Use guides to explore the degree to which patients share commonalities with the traits generally attributed to their cultural group. You need to be informed about traditional characteristics of cultural groups while recognizing that culture is constantly evolving and unique for each individual.

NURSING IMPLEMENTATION

Although the issues associated with health disparities can seem overwhelming, a number of strategies are available to reduce and ultimately eliminate health disparities. Table 2-9 presents nursing interventions to reduce health disparities.

ADVOCACY. The solutions to reduce health disparities often rest with the policy makers. Economic issues often determine health care delivery. Access and public policy decisions determine who is eligible for federal and state health insurance coverage. You, along with the social worker, can help by identifying key resources in the community, including transportation services, reduced-fee screening programs, and appropriate federal and state offices for Medicaid and Medicare.

You can be an advocate by finding and evaluating information on appropriate and individualized treatment and in navigating the health care system. One powerful strategy for reducing health disparities is to increase the number of underrepresented populations in the health care professions (Fig. 2-9).

TABLE 2-9 NURSING INTERVENTIONS TO REDUCE HEALTH DISPARITIES

- Treat all patients equally.
- Be aware of your own biases or prejudices and work toward eliminating them.
- Learn about services and programs that focus on specific cultural/ethnic groups.
- Inform patients about health care services available for their specific cultural/ethnic group.
- Make sure the same standards of care are followed for all patients regardless of culture or ethnicity.
- Identify health care practices and cultural practices that are important to cultural and ethnic identity.
- Participate in research focused on understanding and improving care to culturally and ethnically diverse populations.
- Identify stereotypic attitudes toward a culture/ethnic group that may interfere with getting appropriate health care.
- Support patients of specific cultural/ethnic groups who are fearful about traveling outside the accepted neighborhood for health care services.
- Advocate for patients of specific cultural/ethnic groups to receive health care services that pay special attention to English-language limitations and cultural health practices.
- Learn advocacy and interpersonal strategies from leaders of specific cultural/ethnic groups. For example, African Americans may respond to themes such as "do it for your loved ones." Asian Americans may respond to fear of dependency themes.
- Ensure availability of culturally appropriate patient educational resources.

FIG. 2-9 A Navajo nurse instructs a Navajo patient.

STANDARDIZED GUIDELINES. The use of standardized evidence-based care guidelines can reduce disparities in diagnosis and treatments. For example, guidelines for the management of hypertension are based on the patient's blood pressure, symptoms, history, and laboratory values rather than other characteristics such as gender, age, or culture. Racial or cultural differences in outcomes are reduced when the guidelines are followed. In addition, recommendations related to cultural competency will guide you in your learning and practice.[41]

The National Standards for Culturally and Linguistically Appropriate Services in Health Care (CLAS standards) are guidelines that improve the quality of health care. The CLAS standards provide practical guidance for care of people with limited English proficiency and of diverse cultural backgrounds. These recommendations and resources for health care providers

and organizations are available at the Think Cultural Health website listed in the Resources at the end of this chapter.

COMMUNICATION. Improving interpersonal skills is an important first step in reducing health disparities and providing culturally competent care. Effective communication between you and your patient is most likely to occur when both parties understand the meaning of that communication, whether it is through gestures, spoken words, or voice tones. To show respect for the patient, you should take into account the patient's usual communication style. For instance, a health history should start out in an unhurried manner and in a way that is appropriate for the culture. In some cultures it is best to start with general rather than direct questions. For some cultures it is most effective to engage in "small talk," with the discussion including answers that may seem to be unrelated to the questions. If you appear to be "too busy," communication may be impaired.

When meeting a patient or family member, introduce yourself and indicate how you would like them to address you—whether they should use first names; Mr., Ms., or Mrs.; or a title, such as nurse. Also ask the patient how he or she prefers to be addressed. This shows respect and will help you begin the relationship in a culturally appropriate manner.

If you need to gather personal information, it is important to understand the most effective approach to use. For instance, when talking with people from some cultural groups, it is imperative that you take time to establish trust and listen to the patient's responses to questions. There may be long silences as the person thinks about the question, showing respect by giving the question appropriate consideration before answering. Take time to listen and help establish trust.

TABLE 2-10 USING A MEDICAL INTERPRETER

Choosing an Interpreter

- Use an agency interpreter if possible.
- Use a trained medical interpreter who knows how to interpret, has a health care background, understands patients' rights, and can help with advice about the cultural relevance or appropriateness of the health care plan and instructions.
- Use a family member only if necessary. Be aware of limitations if the family member does not understand medical terms, is younger or a different gender than the patient, or is not aware of the health care procedures or medical ethics.
- Interpreter should be able to do the following:
  - Translate the patient's nonverbal as well as verbal communication.
  - Translate the message into understandable terms.
  - Act as a patient advocate to represent the patient's needs to the health care team.
  - Be culturally competent and understand how to provide teaching instructions.

Strategies for Working With an Interpreter

- If possible, have the interpreter meet with the patient ahead of time to establish rapport before the interpreting begins.
- Speak slowly.
- Maintain eye contact with the patient.
- Talk to the patient, not the interpreter.
- Use simple language with as few medical terms as possible.
- Speak one or two sentences at a time to allow for easier translation.
- Avoid raising your voice during the interaction.
- Obtain feedback to be certain the patient understands.
- Plan on taking twice as long to complete the interaction.

Some cultures, such as the Hmong, rely on oral communication. When working with patients who are from an oral culture, it is important to include oral instructions during the teaching-learning process.

Do not try to serve as an interpreter if your patient does not understand English because this could lead to misunderstandings. Get the assistance of a person who is qualified to do medical interpretation when you cannot speak the patient's primary language (Table 2-10). Interpreters are available by phone anywhere in the United States through a fee-based service and should be used rather than a family member. Table 2-11 provides guidelines for communicating when no interpreter is available. With the large number of immigrants and the many

TABLE 2-11 GUIDELINES FOR COMMUNICATING WHEN NO INTERPRETER IS AVAILABLE

1. Be polite and formal.
2. Pronounce name correctly. If unsure, ask about the correct pronunciation of the name. Use proper titles of respect, such as "Mr.," "Mrs.," "Ms.," "Dr." Greet the person using the last or complete name.
   Gesture to yourself and say your name.
   Offer a handshake or nod. Smile.
3. Proceed in an unhurried manner. Pay attention to any effort by the patient or family to communicate.
4. Speak in a low, moderate voice and avoid excessive hand gestures. Remember that there is a tendency to raise the volume and pitch of your voice when the listener appears not to understand. The listener may perceive that you are shouting or angry.
5. Use any words that you might know in the person's language. This indicates that you are aware of and respect his or her culture.
6. Use simple words, such as "pain" instead of "discomfort." Avoid medical jargon, idioms, and slang. Avoid using contractions (e.g., don't, can't, won't). Use nouns repeatedly instead of pronouns.
   Example:
   Do not say: "He has been taking his medicine, hasn't he?"
   Do say: "Does Juan take medicine?"
7. Pantomime words and simple actions while you verbalize them.
8. Give instructions in the proper sequence.
   Example:
   Do not say: "Before you rinse the bottle, sterilize it."
   Do say: "First, wash the bottle. Second, rinse the bottle."
9. Discuss one topic at a time. Avoid using conjunctions.
   Example:
   Do not say: "Are you cold and in pain?"
   Do say: "Are you cold [while pantomiming]? Are you in pain?"
10. Validate whether the person understands by having him or her repeat instructions, demonstrate the procedure, or act out the meaning.
11. Write out several short sentences in English and determine the person's ability to read them.
12. Try a third language. Many Indochinese people speak French. Europeans often know two or more languages. Try Latin words or phrases. Use English words that have Latin roots (e.g., use precipitation instead of rain).
13. Ask the person's family and friends who could serve as an interpreter.
14. Use websites that translate words from one language to another. Some of them also have audio to help you know how to say the word correctly.
15. Obtain phrase books from a library or bookstore, make or purchase flash cards, contact hospitals for a list of interpreters, and use both a formal and an informal network to locate a suitable interpreter.

Source: Jarvis C: *Physical examination and health assessment,* ed 6, Philadelphia, 2012, Saunders.

different cultural groups, it is highly likely that you will encounter patients who do not speak English.

A dictionary that translates from both your language and the patient's language (e.g., Spanish-English and English-Spanish dictionary) is helpful. You can look up questions and potential answers in several languages using these types of dictionaries. Many websites translate words and documents from one language into another (see Informatics in Practice box).

It is helpful to have resources for those cultural groups who frequently use the health care facility. This is especially beneficial when a qualified medical interpreter is not readily available and you need to learn important phrases in another language.

INFORMATICS IN PRACTICE

Use of Translation Applications

- Communication barriers can negatively affect the type of care received by non–English-speaking patients.
- Use a language translation app to help you translate one language into another language.
- Some apps allow you to speak critical phrases and have the translation immediately spoken back to you or the patient in a natural human voice with the proper accent.
- Check the policy of the health care institution on the use of medical interpreters or translators, including the use of apps for translation.

CASE STUDY

Health Disparities

Patient Profile

A.Z. is a 75-year-old woman who came to the United States from Russia 10 years ago with her daughter, her son-in-law, and their five children. She has a number of health problems, including coronary artery disease, osteoarthritis in her left hip, and diabetes. Her daughter is the primary caregiver and frequently brings her to the urban community health clinic for a variety of health-related complaints. Recently A.Z. has been experiencing memory problems.

The visits to the clinic tend to be chaotic and time consuming for the clinic staff. The entire family comes to the health clinic with A.Z. Because English is a second language for all of the adult family members, the staff relies on the oldest granddaughter to translate.

At this clinic visit A.Z. is complaining of shortness of breath. Through her granddaughter's translation, she tells the nurse that she is having trouble walking up the stairs in the apartment building and can no longer attend her Russian Orthodox church. The nurse does the history and assessment; checks her blood glucose, which is within normal limits; and advises that she get more exercise. Given A.Z.'s memory problems and limited English, the nurse does not complete a 24-hour dietary recall or counsel her or the family about diabetes management. A.Z. is scheduled for an appointment with the cardiologist for an evaluation of her cardiac disease. Two weeks later, when she is seen by the cardiologist, her shortness of breath is much worse and she is having chest pain. She is hospitalized immediately.

Meanwhile, the clinic supervisor is completing a chart audit for the clinic's quality review program. She is reviewing A.Z.'s chart and notices that, although she has been a patient in the clinic for 3 years, she has never received instructions on blood glucose monitoring or general diabetes management. The clinic has a nurse diabetes educator who teaches individual patients and groups of patients with diabetes. The clinic manager reviews these findings with the nurse and asks why she has not recommended that A.Z. see the diabetes educator. The nurse states that with all of the chaos in the family, A.Z.'s memory problems, and the language barrier, she just assumed that A.Z. would not benefit from the consultation.

Discussion Questions

1. What type of health disparity has A.Z. experienced?
2. What factors led to her not receiving the standard of care?
3. What additional assessment should have been done at the initial visit?
4. What strategies might have worked to enhance patient education?
5. How would you assess A.Z.'s religious and spiritual needs?
6. If you were the clinic manager, how would you recommend that the nurse improve her practice?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg.*

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. What is the leading determinant of a patient's health?
   - a. Behavior
   - b. Family history of disease
   - c. Home and work environment
   - d. Type and quality of medical care received
2. In identifying patients at the greatest risk for health disparities, the nurse would note that
   - a. patients who live in urban areas have readily available access to health care services.
   - b. cultural differences exist in patients' ability to communicate with their health care provider.
   - c. a patient receiving care from a health care provider of a different culture would have decreased quality of care.
   - d. men are more likely than women to have their cardiovascular disease symptoms ignored by their health care provider.
3. Forcing one's own cultural beliefs and practices on another person is an example of
   - a. stereotyping.
   - b. ethnocentrism.
   - c. cultural relativity.
   - d. cultural imposition.
4. Which statement most accurately describes cultural factors that may affect health?
   - a. Diabetes and cancer rates differ by cultural/ethnic groups.
   - b. Most patients find that religious rituals help them during times of illness.
   - c. There are limited ethnic variations in physiologic responses to medications.
   - d. Silence during a nurse-patient interaction usually means that the patient understands the instructions.

5. When communicating with a patient who speaks a language that the nurse does not understand, it is important to first attempt to
   a. have a family member translate.
   b. use a trained medical interpreter.
   c. use specific medical terminology so there will be no mistakes.
   d. focus on the translation rather than nonverbal communication.
6. As part of the nursing process, cultural assessment is best accomplished by
   a. judging the patient's cultural values based on observations.
   b. using a cultural assessment guide as part of the nursing process.
   c. seeking guidance from a nurse from the patient's cultural background.
   d. relying on the nurse's previous experience with patients from that cultural group.
7. Nurses play an important role in reducing health disparities. One important mechanism to do this is to
   a. discourage use of evidence-based practice guidelines.
   b. insist that patients adhere to the *Healthy People 2020* guidelines.
   c. teach patients to use the Internet to find resources related to their health.
   d. engage in active listening and establish relationships with patients and families.
8. What is the first step in developing cultural competence?
   a. Create opportunities to interact with a variety of cultural groups.
   b. Examine the nurse's own cultural background, values, and beliefs about health and health care.
   c. Learn about a multitude of folk medicines and herbal substances that different cultures use for self-care.
   d. Learn assessment skills for different cultural groups, including cultural beliefs and practices and physical assessments.

1. a, 2. b, 3. d, 4. a, 5. b, 6. b, 7. d, 8. b.

LEARNING OUTCOMES

1. Explain the purpose, components, and techniques related to a patient's health history and physical examination.
2. Obtain a nursing history using a functional health pattern format.
3. Select appropriate techniques of inspection, palpation, percussion, and auscultation for physical examination of a patient.
4. Differentiate among comprehensive, focused, and emergency types of assessment in terms of indications, purposes, and components.

KEY TERMS

auscultation, p. 42
database, p. 36
functional health patterns, p. 38
inspection, p. 41
nursing history, p. 37
objective data, p. 37
palpation, p. 41
percussion, p. 41
subjective data, p. 37

You will obtain a patient's health history and perform a physical examination during the assessment phase of the nursing process. The findings of your assessment (1) contribute to a database that identifies the patient's current and past health status and (2) provide a baseline against which future changes can be evaluated. The purpose of the nursing assessment is to enable you to make clinical judgments or diagnoses about your patient's health status.[1] Assessment is identified as the first step of the nursing process, but it is performed continually throughout the nursing process to validate nursing diagnoses, evaluate nursing interventions, and determine whether patient outcomes and goals have been met.

The language of assessment is complex, with many overlapping and confusing terms. In this text, *assessment* describes a hands-on data collection process, whereas a *database* identifies a specific list of information (data) to be collected. For example, a *comprehensive database* would be completed for a patient who is being admitted to a hospital by doing a physical examination, a health history, and a psychosocial assessment.

DATA COLLECTION

In the broadest sense, the **database** is all the health information about a patient. This includes the nursing history and physical examination, the medical history and physical examination, results of laboratory and diagnostic tests, and information contributed by other health professionals. The nurse and physician both perform a patient history and a physical examination, but they use different formats and analyze the data based on their discipline's focus.

Medical Focus

A *medical history* is designed to collect data to be used primarily by the physician to determine risk for disease and diagnose medical conditions. The medical history is usually collected by a member of the health care team (e.g., physician, advanced practice nurse [APN], resident, physician's assistant, medical student). The health care provider's physical examination and laboratory and diagnostic tests assist in establishing medical

Reviewed by Misty Hobart, RN, MSN, ARNP, Department Chair, Nursing, Spokane Community College, Spokane, Washington; and Vera Kunte, RN-BC, MSN, Nurse Educator, Thomas Edison State College, Cary Edwards School of Nursing, Trenton, New Jersey.

diagnoses and evaluating treatments. The information collected and reported by the health care provider is also used by nurses and other members of the health care team (e.g., pharmacist, physical therapist, dietitian, social worker) within the focus of their care. For example, the abnormal results of a neurologic examination by an APN may assist in the diagnosis of a stroke. You may use the same results of the neurologic examination to identify a nursing diagnosis of risk for falls. A physical therapist may also use this information to plan therapy involving exercise and ambulatory aids.

Nursing Focus

The focus of nursing care is the diagnosis and treatment of human responses to actual or potential health problems or life processes. The information obtained from the **nursing history** and physical examination is used to determine the patient's strengths and responses to a health problem. For example, for the patient with a medical diagnosis of diabetes mellitus, the patient's responses may include anxiety or a lack of knowledge about self-management of the condition. This patient may also experience the physical response of fluid volume deficit because of the abnormal fluid loss caused by hyperglycemia. These human responses to the condition of diabetes are diagnosed and treated by nurses. During the nursing history interview and physical examination, you will obtain and record the necessary data to support the identification of nursing diagnoses (Fig. 3-1).

Types of Data

The database includes both subjective and objective data. **Subjective data,** also known as *symptoms,* are collected by interviewing the patient and/or caregiver during the nursing history. This type of data includes information that can be described or verified only by the patient or caregiver. It is what the person tells you either spontaneously or in response to direct questioning.

Objective data, also known as *signs,* are data that can be observed or measured. You obtain this type of data using inspection, palpation, percussion, and auscultation during the physical examination. Objective data are also acquired by diagnostic testing. Usually subjective data are obtained by interview, and objective data are obtained by physical examination.

FIG. 3-1 Obtaining and recording data from a nursing history and physical examination using a computer.

However, patients often provide subjective data while you are performing the physical examination. You will also observe objective signs while interviewing the patient. All of the findings related to a specific problem, whether subjective or objective, are known as *clinical manifestations* of that problem.

Interview Considerations

The purpose of the patient interview is to obtain a health history (i.e., subjective data) about the patient's past and present health state. Effective communication is a key factor in the interview process. Creating a climate of trust and respect is critical to establishing a therapeutic relationship.[2] You need to communicate acceptance of the patient as an individual by using an open, responsive, nonjudgmental approach. You communicate not only through language but also in your manner of dress, gestures, and body language. Modes of communication are learned through one's culture, influencing not only the words, gestures, and postures one uses, but also the nature of information that is shared with others (see Chapter 2). In addition to understanding the principles of effective communication, you need to develop a personal style of relating to patients. Although no single style fits all people, your wording of questions can increase the probability of eliciting the needed information. The ease of asking questions, particularly those related to sensitive areas such as sexual functioning, comes with experience.

The amount of time you need to complete a nursing history varies with the format used and your experience. The nursing history may be completed in one or several sessions, depending on the setting and the patient. For example, you may need to plan several short sessions for an older adult patient with a low energy level to allow time for the patient to provide the needed information. You must also make a judgment about the amount of information collected on initial contact with the patient. In interviews with patients with chronic disease, patients in pain, and patients in emergency situations, ask only those questions that are pertinent to a specific problem. You can complete the health history interview at a more appropriate time.

Judge the reliability of the patient as a historian. An older adult may give a false impression about his or her mental status because of a prolonged response time or visual and hearing impairments. The complexity and long duration of health problems may make it difficult for an older adult or a chronically ill younger patient to be an accurate historian.

It is important for you to determine the patient's priority concerns and expectations, since your priorities may be different from the patient's. For example, your priority may be to complete the health history, whereas the patient is interested only in relief from symptoms. Until the patient's priority need is met, you will probably be unsuccessful in obtaining complete and accurate data.

Symptom Investigation

At any time during the assessment the patient may report a symptom such as pain, fatigue, or weakness. Symptoms experienced by the patient are not necessarily observed, so the symptom must be investigated. Table 3-1 shows a mnemonic (PQRST) to help you remember the areas to investigate if a symptom is reported. The information you receive may help determine the cause of the symptom. A common symptom that you will assess is pain (see Chapter 9). For example, if a patient states that he has "pain in his leg," you would assess and record the data using PQRST.

TABLE 3-1 INVESTIGATION OF PATIENT-REPORTED SYMPTOM

	Factor	Questions for Patient and Caregiver	Record
P	Precipitating and Palliative	Were there any events that came before the symptom? What makes it better? Worse? What have you done for the symptom? Did this help?	Influence of physical and emotional activities. Patient's attempts to alleviate (or treat) the symptom.
Q	Quality	Tell me what the symptom feels like (e.g., aching, dull, pressure, burning, stabbing).	Patient's own words (e.g., "Like a pinch or stabbing feeling").
R	Radiation	Where do you feel the symptom? Does it move to other areas?	Region of the body. Local or radiating, superficial or deep.
S	Severity	On a scale of 0-10, with 0 meaning no pain and 10 being the worst pain you could imagine, what number would you give your symptom?	Pain rating number (e.g., 5/0-10 scale).
T	Timing	When did the symptom start? Any particular time of day, week, month, or year? Has the symptom changed over time? Where are you and what are you doing when the symptom occurs?	Time of onset, duration, periodicity, and frequency. Course of symptoms. Where patient is and what patient is doing when the symptom occurs.

Has right midcalf pain that usually occurs at work when climbing stairs after lunch **(P).** Pain is alleviated by stopping and resting for 2 to 3 minutes. Patient states he has been "eating a banana every day for extra potassium" but "it hasn't helped" **(P).** Pain is described as "stabbing" and is non-radiating **(Q, R).** Pain is so severe (rating 9 on 0-10 scale) that patient cannot continue activity **(S).** Onset is abrupt, occurring once or twice daily. It last occurred yesterday while cutting the lawn **(T).**

Data Organization

Assessment data must be systematically obtained and organized so you can readily analyze and make judgments about the patient's health status and any health problems. Some assessment forms are organized using body systems. Although helpful, these types of forms may be incomplete because they omit areas such as health promotion behaviors, sleep, coping, and values.

Functional health patterns, developed by Gordon,[3] provide the framework used throughout this textbook for obtaining a nursing history. This format includes an initial collection of important health information followed by assessment of 11 areas of health status or function (see Table 3-2). Data organized in this format promote the identification of areas of wellness (or positive function), as well as health problems.[2]

CULTURALLY COMPETENT CARE

ASSESSMENT

The process of obtaining a health history and performing a physical examination is an intimate experience for both you and the patient. As noted earlier in the chapter, one's culture influences patterns of communication and what information is shared with others. During the interview and physical examination, be sensitive to issues of eye contact, space, modesty, and touching, as discussed in Chapter 2. Adhering to cultural practices related to male-female relationships and gender identification is especially important during the physical examination. To avoid violating any culturally based practices, ask the patient about cultural values and whether the patient would like to have someone present during the history or physical examination.[1]

NURSING HISTORY: SUBJECTIVE DATA

Important Health Information

Important health information provides an overview of past and present medical conditions and treatments. Past health history, medications, allergies, and surgery or other treatments are included in this part of the history.

DELEGATION DECISIONS

Assessment and Data Collection

Ongoing data collection is expected of all members of the health care team. In acute care the initial (admission) nursing assessment must be completed by the registered nurse (RN).

Role of Registered Nurse (RN)

- On admission, do a comprehensive assessment (see Table 3-6).
- Obtain patient's health history by interviewing patient and/or caregiver.
- Perform physical examination using inspection, palpation, percussion, and auscultation as appropriate.
- Document findings from the health history and physical examination in the patient's record.
- Organize patient data into functional health patterns.
- Develop and prioritize nursing diagnoses and collaborative problems for the patient.
- Throughout hospitalization, perform focused assessments based on patient's history or clinical manifestations (see Table 3-6).

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Collect and document specific patient data as delegated by the RN (after the RN has developed the plan of care based on the admission assessment).
- Perform focused assessment based on patient's history, clinical manifestations, or as instructed by the RN (see Table 3-6).

Role of Unlicensed Assistive Personnel (UAP)

- Take and document vital signs.
- Measure and document patient's height and weight.
- Report abnormal vital signs to RN.
- Report patient's subjective complaints to RN.

Past Health History. The past health history provides information about the patient's prior state of health. Ask the patient about major childhood and adult illnesses, injuries, hospitalizations, and surgeries. Specific questions are more effective than simply asking whether the patient has had any illness or health problems in the past. For example, "Do you have a history of diabetes?" will elicit better information than "Do you have any chronic illnesses?"

Medications. Ask the patient for specific details related to past and current medications, including prescription drugs, over-the-counter drugs, vitamins, herbal products, and dietary supplements. Patients frequently do not consider herbal products and dietary supplements as drugs. It is important to specifically ask about their use because they can interact adversely with existing or newly prescribed medications (Complementary & Alternative Therapies box).

COMPLEMENTARY & ALTERNATIVE THERAPIES

Assessment of Use of Herbs and Dietary Supplements

Why Assessment Is Important

- Herbal products and dietary supplements may have side effects or may interact adversely with prescription or OTC medications.
- Patients at high risk for drug-herb interactions include those taking anticoagulant, antihypertensive, antidepressant-psychotic, or immune-regulating therapy and patients undergoing anesthesia.
- Many patients do not tell health care providers that they are using herbal products and dietary supplements. They may fear health care professionals will disapprove of their use.
- Many herbal preparations contain a variety of ingredients. Ask the patient or caregiver to bring labeled containers to the health care site to determine the composition of the products.

Nurse's Role

- Patients typically share this information with you if they are specifically asked.
- Create an accepting and nonjudgmental attitude when assessing use of or interest in herbal products or dietary supplements.
- Use open-ended questions such as, "What types of herbs, vitamins, or supplements do you take?" and "What effects have you noticed from using them?"
- Respond to patients with comments that invite an open-minded discussion.
- Document the use of any herbal product(s) or dietary supplements in the patient record.

Question older adult and chronically ill patients about medication routines. Polypharmacy; changes in absorption, metabolism, reaction to drugs, and elimination of drugs; and surgery and concurrent disease can pose serious potential problems for these patients.[4]

Allergies. Fully explore the patient's history of allergies to medications, contrast media, food, and the environment (e.g., latex, pollen). Include a detailed description of any allergic reaction(s) reported by the patient.

Surgery or Other Treatments. Record all surgeries along with the date of the event, the reason for the surgery, and the outcome. The outcome includes whether the problem was completely resolved or has residual effects. Be sure to ask about and record any blood products the patient received.

Functional Health Patterns

Assess the patient's functional health patterns to identify positive, dysfunctional, and potential dysfunctional health patterns. Dysfunctional health patterns result in nursing diagnoses, and potential dysfunctional patterns identify risk conditions for problems. In addition, you may identify patients with effective health function who express a desire for a higher level of wellness. Examples of specific questions to ask the patient related to the functional health patterns are presented in Table 3-2.

Health Perception–Health Management Pattern. Assessment of the health perception–health management functional health pattern focuses on the patient's perceived level of health and well-being and on personal practices for maintaining health. Ask the patient to describe his or her personal health and any concerns about it. Explore the patient's feelings of effectiveness at staying healthy by asking what helps and what hinders his or her well-being. Ask the patient to rate his or her health as excellent, good, fair, or poor. Be sure to record this information in the patient's own words.

Next, while being culturally sensitive, ask about the type of health care provider the patient uses. For example, if the patient is Native American, a medicine man may be considered the primary health care provider. If the patient is of Hispanic origin, a *curandero* (Hispanic healer who uses folk medicine, herbal products, or magic to treat patients) may be the primary health care provider (see Chapter 2).

The questions for this pattern also seek to identify risk factors by obtaining a thorough family history (e.g., cardiac disease, cancer, genetic disorders), history of personal health habits (e.g., tobacco, alcohol, drug use), and history of exposure to environmental hazards (e.g., asbestos). If the patient is hospitalized, ask about the expectations for this experience. Have the patient describe his or her understanding of the current health problem, including its onset, course, and treatment. These questions obtain information about a patient's knowledge of the health problem and ability to use appropriate resources to manage the problem.

Nutritional-Metabolic Pattern. The processes of ingestion, digestion, absorption, and metabolism are assessed in this pattern. Obtain a 24-hour diet recall from the patient to evaluate the quantity and quality of foods and fluids consumed. If a problem is identified, ask the patient to keep a 3-day food diary for a more careful analysis of dietary intake. Assess the impact of psychologic factors such as depression, anxiety, stress, and self-concept on nutrition. Additionally, determine socioeconomic and cultural factors such as food budget, who prepares the meals, and food preferences. Determine whether the patient's present condition has interfered with eating and appetite by exploring any symptoms of nausea, intestinal gas, or pain. Food allergies should be differentiated from food intolerances, such as lactose or gluten intolerance.

Elimination Pattern. Assess bowel, bladder, and skin function in this pattern. Ask the patient about the frequency of bowel and bladder activity, including laxative and diuretic use. The skin is assessed in the elimination pattern in terms of its excretory function.

Activity-Exercise Pattern. Assess the patient's usual pattern of exercise, work activity, leisure, and recreation. Question the patient about his or her ability to perform activities of daily living and note any specific problems. Table 3-2 includes a scale for rating the functional levels of common activities.

Sleep-Rest Pattern. This pattern describes the patient's perception of his or her pattern of sleep, rest, and relaxation in a 24-hour period. This information can be elicited by asking, "Do you feel rested when you wake up?"

Cognitive-Perceptual Pattern. Assessment of this pattern involves a description of all of the senses and cognitive functions. In addition, assess pain as a sensory perception in this pattern. (See Chapter 9 for details on pain assessment.) Ask the patient about any sensory deficits that affect the ability to perform activities of daily living. Discuss and record ways in which the patient compensates for any sensory-perceptual problems. To plan for patient teaching, ask the patient how he or she communicates best and what he or she understands about the illness and treatment plan. (See Chapter 4 for details on patient teaching.)

Self-Perception–Self-Concept Pattern. This pattern describes the patient's self-concept, which is critical in determining the way the person interacts with others. Included are attitudes about self, perception of personal abilities, body image, and general sense of worth. Ask the patient for a self-description

TABLE 3-2 HEALTH HISTORY

Functional Health Pattern Format

Demographic Data
Name, address, age, occupation, gender
Race, ethnicity, culture

Important Health Information
Past health history
Medications, supplements
Allergies
Surgery or other treatments

Health Perception–Health Management Pattern
1. Reason for visit?
2. General state of health?
3. Number of colds in past year?
4. Most important things done to keep healthy? Testicular self-examination? Colorectal cancer, hypertension, and cardiac disease risk screening? Papanicolaou (Pap) test? Immunizations such as tetanus, pneumonia, hepatitis, and flu vaccines?
5. Who is your primary care physician or health care provider?
6. Health compliance problems?
7. Cause of illness? Action taken? Results?
8. Things important to you while here?
9. Family health history (e.g., cardiovascular disease, hypertension, cancer, diabetes mellitus, psychiatric illness, genetic disorders)?
10. Illness and injury risk factors (e.g., sexual abuse, intimate partner abuse, violence, use of cigarettes or alcohol, substance abuse)?

Nutritional-Metabolic Pattern
1. Typical daily food intake (describe)? Supplements?
2. Typical daily fluid intake (describe)?
3. Weight loss or gain (amount, time span)?
4. Desired weight?
5. Appetite?
6. Food or eating: Discomfort? Diet restrictions?
7. Change in appetite with anxiety?
8. Heal well or poorly?
9. Skin problems: Lesions? Dryness?
10. Dentition: Dental problems? Well-fitting dentures?
11. Food preferences?
12. Food allergies?

Elimination Pattern
1. Bowel elimination pattern (describe): Frequency? Character? Discomfort? Laxatives? Enemas?
2. Urinary elimination pattern (describe): Frequency? Problem in control? Diuretics?
3. Any external devices?
4. Excess perspiration? Odor problems? Itching?

Activity-Exercise Pattern
1. Sufficient energy for desired or required activities?
2. Exercise pattern? Type? Regularity?
3. Spare time (leisure) activities?
4. Dyspnea? Chest pain? Palpitations? Stiffness? Aching? Weakness?
5. Perceived ability for (rate Functional Level 0-III for each):
   Feeding __ Cooking __ Grooming __
   Bed mobility __ Bathing __ Dressing __
   Toileting __ Shopping __ General mobility __

   Functional Levels
   Level 0: Full self-care
   Level I: Requires use of equipment or device
   Level II: Requires assistance or supervision from another person
   Level III: Is dependent and does not participate

Sleep-Rest Pattern
1. Generally rested and ready for daily activities after sleep?
2. Sleep onset problems? Aids? Dreams (nightmares)? Early awakening?
3. Usual sleep rituals?
4. Usual sleep pattern?

Cognitive-Perceptual Pattern
1. Hearing difficulty? Hearing aids?
2. Vision? Wear glasses? Last checked?
3. Any change in taste? Any change in smell?
4. Any recent change in memory?
5. Easiest way to learn things?
6. Any discomfort? Pain (rating on scale of 0-10)? How managed?
7. Ability to communicate?
8. Understanding of illness?
9. Understanding of treatments?

Self-Perception–Self-Concept Pattern
1. Self-description? Self-perception?
2. Effect of illness on self-image?
3. Relieving factors?

Role-Relationship Pattern
1. Live alone? Family/caregiver? Family structure diagram?
2. Difficult family problems?
3. Family problem solving?
4. Family dependence on you for things? How managing?
5. Family's and others' feelings about illness or hospitalization?*
6. Problems with children? Difficulty handling?*
7. Belong to social groups? Have close friends? Feel lonely (frequency)?
8. Work (school) satisfaction? Income sufficient for needs?*
9. Feel part of or isolated from neighborhood where living?

Sexuality-Reproductive Pattern
1. Any changes or problems in sexual relations?*
2. Effect of illness?
3. Use of contraceptives? Problems?
4. When menstruation started? Last menstrual period? Menstrual problems? Gravida? Para?†
5. Effect of present condition or treatment on sexuality?
6. Sexually transmitted infections?

Coping–Stress Tolerance Pattern
1. Tense a lot of the time? What helps? Use any medications, drugs, alcohol?
2. Have someone to confide in? Available to you now?
3. Recent life changes?
4. Problem-solving techniques? Effective?

Value-Belief Pattern
1. Satisfied with life?
2. Religion important in your life?
3. Conflict between treatment and beliefs?

Other
1. Other important issues?
2. Questions?

Modified from Gordon M: *Manual of nursing diagnosis,* ed 12, Boston, 2010, Jones & Bartlett.
*If appropriate.
†For women.

and about how his or her health condition affects self-concept. Patients' expressions of hopelessness or loss of control frequently reflect an inability to care for oneself.

Role-Relationship Pattern. This pattern reveals the patient's roles and relationships, including major responsibilities. Ask the patient to describe family, social, and work roles and relationships and to rate his or her performance of the expected behaviors related to these. Determine whether patterns in these roles and relationships are satisfactory or whether strain is evident. Note the patient's feelings about how the present condition affects his or her roles and relationships.

Sexuality-Reproductive Pattern. This pattern describes satisfaction or dissatisfaction with personal sexuality and describes reproductive issues. Assessing this pattern is important because many illnesses, surgical procedures, and medications affect sexual function. A patient's sexual and reproductive concerns may be expressed, teaching needs and treatable problems may be identified, and normal growth and development may be monitored through information obtained in this pattern.

Obtaining information related to sexuality may be difficult for you. However, it is important to take a health history and screen for sexual function and dysfunction in order to provide information or refer the patient to a more experienced professional.

Coping–Stress Tolerance Pattern. This pattern describes the patient's general coping pattern and the effectiveness of the coping mechanisms. Assessment of this pattern involves analyzing the specific stressors or problems that confront the patient, the patient's perception of the stressors, and the patient's response to the stressors. Document any major losses or stressors experienced by the patient in the previous year. Note strategies used by the patient to deal with stressors and relieve tension, as well as individuals and groups that make up the patient's social support networks.

Value-Belief Pattern. This pattern describes the values, goals, and beliefs (including spiritual) that guide health-related choices. Document the patient's ethnic background and the effects of culture and beliefs on health practices. Note and honor the patient's wishes about continuation of religious or spiritual practices and the use of religious articles.

PHYSICAL EXAMINATION: OBJECTIVE DATA

General Survey

After the nursing history, make a *general survey statement.* This is your general impression of a patient, including behavioral observations. This initial survey is considered a scanning procedure that begins with your first encounter with the patient and continues during the health history interview.

Although you may include other data that seem pertinent, the major areas included in the general survey statement are (1) body features, (2) mental state, (3) speech, (4) body movements, (5) obvious physical signs, (6) nutritional status, and (7) behavior. Vital signs and body mass index (BMI) (calculated from height and weight [kg/m^2]) may be included. The following is a sample of a general survey statement:

> A.H. is a 34-year-old Hispanic woman, BP 130/84, P 88, R 18. No distinguishing body features. Alert but anxious. Speech rapid with trailing thoughts. Wringing hands and shuffling feet during interview. Skin flushed, hands clammy. Overweight relative to height (BMI = 28.3 kg/m^2). Sits with eyes downcast and shoulders slumped and avoids eye contact.

Physical Examination

The *physical examination* is the systematic assessment of a patient's physical status. Throughout the physical examination, explore any positive findings using the same criteria used during the investigation of a symptom in the nursing history (see Table 3-1). A *positive finding* indicates that the patient has or has had the particular problem or sign under discussion (e.g., if the patient with jaundice has an enlarged liver, it is a positive finding). Relevant information about this problem should then be gathered.

Negative findings may also be significant. A *pertinent negative* is the absence of a sign or symptom usually associated with a problem. For example, peripheral edema is common with advanced liver disease. If edema is not present in a patient with advanced liver disease, this should be specifically noted as "no peripheral edema."

Techniques. Four major techniques are used in performing the physical examination: inspection, palpation, percussion, and auscultation. The techniques are usually performed in this sequence, except for the abdominal examination (inspection, auscultation, percussion, and palpation). Performing percussion and palpation of the abdomen before auscultation can alter bowel sounds and produce false findings. Not every assessment area requires the use of all four assessment techniques (e.g., musculoskeletal system requires only inspection and palpation).

Inspection. **Inspection** is the visual examination of a part or region of the body to assess normal conditions or deviations. Inspection is more than just looking. This technique is deliberate, systematic, and focused. Compare what is seen with the known, generally visible characteristics of the body part that you are inspecting. For example, most 30-year-old men have hair on their legs. Absence of hair may indicate a vascular problem and the need for further investigation, or it may be normal for a patient of a particular ethnicity (e.g., Filipino men have little body hair). Always compare one side of the patient's body to the other to assess bilaterally for any abnormal findings.

Palpation. **Palpation** is the examination of the body using touch. Using light and deep palpation can yield information related to masses, pulsations, organ enlargement, tenderness or pain, swelling, muscular spasm or rigidity, elasticity, vibration of voice sounds, crepitus, moisture, and texture. Different parts of the hand are more sensitive for specific assessments. For example, use the palmar surface (base of fingers) to feel vibrations, the dorsa (backs) of your hands and fingers to assess temperature, and tips of your fingers to palpate the abdomen[1] (Fig. 3-2).

Percussion. **Percussion** is a technique that produces a sound and vibration to obtain information about the underlying area (Fig. 3-3). Evaluate the sounds and vibrations relative to the underlying structures. Deviation from an expected sound may indicate a problem. For example, the usual percussion sound in the right lower quadrant of the abdomen is tympany. Dullness in this area may indicate a problem that should be investigated. (Specific percussion sounds of various body parts and regions are discussed in the appropriate assessment chapters.)

Auscultation. **Auscultation** is listening to sounds produced by the body with a stethoscope to assess normal conditions and deviations from normal. This technique is particularly useful in evaluating sounds from the heart, lungs, abdomen, and vascular

FIG. 3-2 Palpation is the examination of the body using touch. (From Jarvis C: *Physical examination and health assessment,* ed 6, St Louis, 2012, Saunders.)

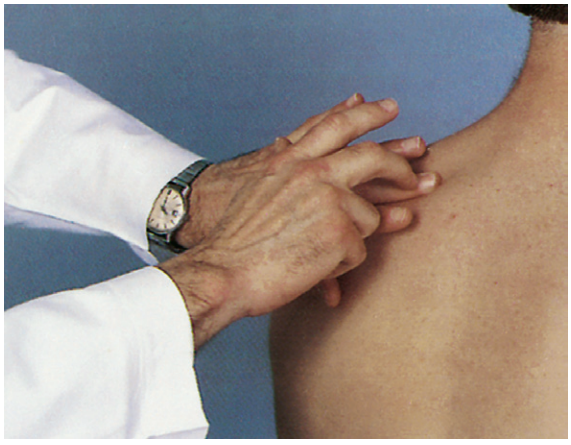

FIG. 3-3 Percussion technique. Tapping the interphalangeal joint. Only the middle finger of the nondominant hand should be in contact with the skin surface.

system. The bell of the stethoscope is more sensitive to low-pitched sounds (e.g., heart murmurs). The diaphragm of the stethoscope is more sensitive to high-pitched sounds (e.g., bowel sounds). Some stethoscopes have only a diaphragm, designed to transmit low- and high-pitched sounds. To listen for low-pitched sounds, hold the diaphragm lightly on the skin. For high-pitched sounds, press the diaphragm firmly on the skin[1] (Fig. 3-4). (Specific auscultatory sounds and techniques are discussed in the appropriate assessment chapters.)

Equipment. The equipment needed for the physical examination should be easily accessible (Table 3-3). Organizing equipment before the examination saves time and energy for you and the patient. (The uses of specific equipment are discussed in the appropriate assessment chapters.)

Organization of Examination. Perform the physical examination systematically and efficiently. Provide explanations to the patient as the examination proceeds, and consider the patient's comfort, safety, and privacy. You are less likely to forget a procedure, a step in the sequence, or a portion of the body if you follow the same sequence every time. Table 3-4 presents an outline for a physical examination that is organized and complete.

FIG. 3-4 Auscultation is listening to sounds produced by the body to assess normal conditions and deviations from normal.

TABLE 3-3 EQUIPMENT FOR PHYSICAL EXAMINATION*

- Stethoscope (with bell and diaphragm or a dual-purpose diaphragm; tubing 15-18 inches [38-46 cm])
- Watch (with second hand or digital)
- Blood pressure cuff
- Eye chart (wall chart or Snellen pocket eye card)
- Pocket flashlight
- Tongue blades
- Cotton balls
- Percussion hammer
- Alcohol swabs
- Patient gown
- Paper cup with water
- Examining table or bed

*These are examples of commonly used equipment; other equipment may be used depending on the situation.

Adaptations of the physical examination are often useful for the older adult patient, who may have age-related problems such as decreased mobility, limited energy, and perceptual changes.[5] An outline listing some of the useful adaptations is found in Table 3-5.

Recording Physical Examination. Only record abnormal findings during the actual examination. At the conclusion of the examination, combine the normal and abnormal findings in a carefully compiled record. An example of how to record findings of a physical examination of a healthy adult can be found in eTable 3-1 on the website for this chapter. See Table 5-6 to locate age-related assessment findings in the book.

TYPES OF ASSESSMENT

Various types of assessment are used to obtain information about a patient. These approaches can be divided into three types: comprehensive, focused, and emergency (Table 3-6 on p. 45). You need to decide what type of assessment to perform based on the clinical situation (e.g., admission history and physical examination, start of shift, throughout shift). Sometimes the health care agency provides guidelines, and other times it is a nursing judgment.

Comprehensive Assessment

A *comprehensive assessment* includes a detailed health history and physical examination of one body system or many body systems (see Table 3-6). This is typically done on admission to the hospital or onset of care in a primary care setting.

TABLE 3-4 OUTLINE FOR PHYSICAL EXAMINATION

1. General Survey

Observe general state of health (patient is seated).

- Body features
- Level of consciousness and orientation
- Speech
- Body movements and carriage
- Physical appearance
- Nutritional status
- Stature

2. Vital Signs

Record vital signs.

- Blood pressure—both arms for comparison
- Apical/radial pulse
- Respiration
- Temperature
- Record height and weight; calculate body mass index (BMI)

3. Integument

Inspect and palpate skin for the following:

- Color
- Breakdown, lacerations, lesions
- Scars, tattoos, piercings
- Bruises, rash
- Edema
- Moisture
- Texture
- Temperature
- Turgor
- Vascularity

Inspect and palpate nails for the following:

- Color
- Lesions
- Size
- Flexibility
- Shape
- Angle
- Capillary refill time

4. Head and Neck

Inspect and palpate head for the following:

- Shape and symmetry of skull
- Masses
- Tenderness
- Hair
- Scalp
- Skin
- Temporal arteries
- Temporomandibular joint
- Sensory (CN V, light touch, pain)
- Motor (CN VII, shows teeth, purses lips, raises eyebrows)
- Looks up, wrinkles forehead (CN VII)
- Raises shoulders against resistance (CN XI)

Inspect and palpate (occasionally auscultate) neck for the following:

- Skin (vascularity and visible pulsations)
- Symmetry
- Range of motion
- Pulses and bruits (carotid)
- Midline structure (trachea, thyroid gland, cartilage)
- Lymph nodes (preauricular, postauricular, occipital, mandibular, tonsillar, submental, anterior and posterior cervical, infraclavicular, supraclavicular)

Inspect and lightly palpate eyes for the following:

- Visual acuity
- Eyebrows
- Position and movement of eyelids (CN VII)
- Visual fields
- Extraocular movements (CN III, IV, VI)
- Cornea, sclera, conjunctiva
- Pupillary response (CN III)
- Red reflex

Inspect and palpate nose and sinuses for the following:

- External nose: shape, blockage
- Internal nose: patency of nasal passages, shape, turbinates or polyps, discharge
- Frontal and maxillary sinuses

Inspect and palpate ears for the following:

- Placement
- Pinna
- Auditory acuity (whispered voice, ticking watch) (CN VIII)
- Mastoid process
- Auditory canal
- Tympanic membrane

Inspect and palpate mouth for the following:

- Lips (symmetry, lesions, color)
- Buccal mucosa (Stensen's and Wharton's ducts)
- Teeth (absence, state of repair, color)
- Gums (color, receding from teeth)
- Tongue for strength (asymmetry, ability to stick out tongue, side to side, fasciculations) (CN XII)
- Palates
- Tonsils and pillars
- Uvular elevation (CN IX)
- Posterior pharynx
- Gag reflex (CN IX and X)
- Jaw strength (CN V)
- Moisture
- Color
- Floor of mouth

5. Extremities

Observe size and shape, symmetry and deformity, involuntary movements. Inspect and palpate arms, fingers, wrists, elbows, shoulders for the following:

- Strength
- Range of motion
- Joint pain
- Swelling
- Pulses (radial, brachial)
- Sensation (light touch, pain, temperature)
- Test reflexes: triceps, biceps, brachioradialis

Inspect and palpate legs for the following:

- Strength
- Range of motion
- Joint pain
- Swelling, edema
- Hair distribution
- Sensation (light touch, pain, temperature)
- Pulses (dorsalis pedis, posterior tibialis)
- Test reflexes: patellar, achilles, plantar

6. Posterior Thorax

Inspect for muscular development, scoliosis, respiratory movement, approximation of AP diameter.

- Palpate for symmetry of respiratory movement, tenderness of CVA, spinous processes, tumors or swelling, tactile fremitus
- Percuss for pulmonary resonance
- Auscultate for breath sounds
- Auscultate for egophony, bronchophony, and whispered pectoriloquy

7. Anterior Thorax

- Assess breasts for configuration, symmetry, dimpling of skin
- Assess nipples for rash, direction, inversion, retraction
- Inspect for apical impulse, other precordial pulsations
- Palpate the apical impulse and the precordium for thrills, lifts, heaves, tenderness
- Inspect neck for venous distention, pulsations, waves
- Palpate lymph nodes in the subclavian, axillary, and brachial areas
- Palpate breasts
- Auscultate for rate and rhythm; character of S_1 and S_2 in the aortic, pulmonic, Erb's point, tricuspid, mitral areas; bruits at carotid, epigastrium

AP, Anteroposterior; *CN*, cranial nerve; *CVA*, costovertebral angle.

Continued

TABLE 3-4 OUTLINE FOR PHYSICAL EXAMINATION—cont'd

8. Abdomen
- Inspect for scars, shape, symmetry, bulging, muscular position and condition of umbilicus, movements (respiratory, pulsations, presence of peristaltic waves)
- Auscultate for peristalsis (i.e., bowel sounds), bruits
- Percuss then palpate to confirm positive findings; check liver (size, tenderness), spleen, kidney (size, tenderness), urinary bladder (distention)
- Palpate femoral pulses, inguinofemoral nodes, and abdominal aorta

9. Neurologic

Observe motor status.
- Gait
- Toe walk
- Heel walk
- Drift

Observe coordination:
- Finger to nose
- Romberg sign
- Heel to opposite shin

Observe the following:
- Proprioception (position sense of great toe)

10. Genitalia*

Male External Genitalia
- Inspect penis, noting hair distribution, prepuce, glans, urethral meatus, scars, ulcers, eruptions, structural alterations, discharge
- Inspect epidermis of perineum, rectum
- Inspect skin of scrotum; palpate for descended testes, masses, pain

Female External Genitalia
- Inspect hair distribution; mons pubis, labia (minora and majora); urethral meatus; Bartholin's, urethral, Skene's glands (may also be palpated, if indicated); introitus; any discharge
- Assess for presence of cystocele, prolapse
- Inspect perineum, rectum

*If the nurse has the appropriate education, the speculum and bimanual examination of women and the prostate gland examination of men would be performed after this inspection.

TABLE 3-5 GERONTOLOGIC ASSESSMENT DIFFERENCES

Adaptations in Physical Assessment Techniques

General Approach
Keep patient warm and comfortable because loss of subcutaneous fat decreases ability to stay warm. Adapt positioning to physical limitations. Avoid unnecessary changes in position. Perform as many activities as possible in the position of comfort for the patient.

Skin
Handle with care because of fragility and loss of subcutaneous fat.

Head and Neck
Provide a quiet environment free from distraction because of possible sensory impairments (e.g., decreased vision, hearing).

Extremities
Use gentle movements and reinforcement techniques. Avoid having patient hop on one foot or perform deep knee bends because of patient's limited range of motion of the extremities, decreased reflexes, and diminished sense of balance.

Thorax
Adapt examination for changes related to decreased force of expiration, weakened cough reflex, and shortness of breath.

Abdomen
Use caution in palpating patient's liver because it is readily accessible because of a thinner, softer abdominal wall. The older adult patient may have diminished pain perception in the abdominal wall.

Focused Assessment

A *focused assessment* is a more abbreviated history and examination. It is used to evaluate the status of previously identified problems and monitor for signs of new problems. It can be done when a specific problem (e.g., pneumonia) is identified. The patient's clinical manifestations should alert you to the appropriate focused assessment. For example, abdominal pain indicates the need for a focused assessment of the abdomen. Some problems necessitate a focused assessment of more than one body system. A complaint of headache may indicate the need to do musculoskeletal, neurologic, and head and neck examinations. Examples of focused assessments for various body systems can be found in eTable 3-3 on the website for this chapter.

Emergency Assessment

In an emergency or critical situation an *emergency assessment* may be done. This involves the rapid examination and specific questioning of a patient while maintaining vital functions.

Using Assessment Approaches

Assessment in a hospital inpatient setting, particularly in acute care, is markedly different from assessment in other settings. Focused assessment of the hospitalized patient is frequent and performed by many different people. Such a team approach demands a high degree of consistency among different health care professionals.

As you provide ongoing care for a patient, you will be constantly refining your mental image of the patient. As you gain experience, you will form a mental image of a patient's status from a few basic details, such as "85-year-old woman admitted for COPD [chronic obstructive pulmonary disease] exacerbation." Your picture of her becomes clearer as you receive a more complete verbal report, such as length of stay, recent laboratory results, physical findings, and vital signs. Next, perform your own assessment using a focused approach. During your assessment, you will confirm or revise the findings that you read in the medical record and what you heard from other health care professionals.

Keep in mind that the process does not end once you have done your first assessment on a patient during your rounds. You will continue to gather information about all your patients throughout your shift. Everything that you learned previously about each patient is considered in the light of new information. For example, when you are doing a respiratory assessment on your patient with COPD, you hear crackles in her lungs. This finding should lead you to do a cardiovascular assessment because cardiac problems (e.g., heart failure) can also cause crackles. As you gain experience, the importance of new findings will be more obvious to you. Assessment case

TABLE 3-6 TYPES OF ASSESSMENT

The following describes types of assessment that you may use in various situations.

Description	When and Where Performed	Where to Find in Book
Comprehensive		
• Detailed assessment of one body system or many body systems, including those not directly involved in presenting problem or admission diagnosis • Used for head-to-toe assessment	• Onset of care in primary or ambulatory care setting • On admission to hospital or long-term care setting • On initial home care visit	• Assessment chapters for each body system • Outline for physical examination (see Table 3-4) • Head-to-toe (total body) assessment checklist (see eTable 3-2, available on the website for this chapter)
Focused		
• Abbreviated assessment that focuses on one or more body systems that are the focus of care • Includes an assessment related to a specific problem (e.g., pneumonia, specific abnormal laboratory findings) • Monitors for signs of new problems	• Throughout hospital admission—at beginning of a shift and as needed throughout shift • Revisited in ambulatory care setting or home care setting	• Focused assessment boxes in each assessment chapter (all boxes available in eTable 3-3 on website) • Tables on nursing assessment of specific diseases throughout book
Emergency		
• Limited to assessing life-threatening conditions (e.g., inhalation injuries, anaphylaxis, myocardial infarction, shock, stroke) • Conducted to ensure survival; focuses on airway, breathing, circulation, and disability • After lifesaving interventions are initiated, perform brief systematic assessment to identify any and all other injuries or problems	• Performed in any setting when signs or symptoms of a life-threatening condition appear (e.g., emergency department, critical care unit, surgical setting)	• Chapter 69, Table 69-3 and Table 69-5 • Emergency management tables throughout the book and listed in Table 69-1

studies are integrated into all of the assessment chapters for this book to help you develop your assessment skills and knowledge.

Table 3-7 shows how you can perform different types of assessments based on a patient's progress through a given hospitalization. When a patient arrives at the emergency department in acute distress, you will perform an emergency assessment based on the principles of airway, breathing, circulation, disability, and exposure/environmental control (see Chapter 69, Table 69-3). Once the patient is stabilized, you can begin a focused assessment of the respiratory and related body systems. Once the patient is admitted, a comprehensive assessment of all body systems, whether or not they are involved in the current clinical problem, is obtained.

PROBLEM IDENTIFICATION AND NURSING DIAGNOSES

After completing the history and physical examination, analyze the data to develop a list of nursing diagnoses and collaborative problems. See Chapter 1 for a description of the nursing process, including the identification of nursing diagnoses and collaborative problems.

TABLE 3-7 CLINICAL APPLICATION OF VARIOUS TYPES OF ASSESSMENT

The following is an example of how various types of assessment would be used for a patient progressing from the emergency department to a clinical unit of a hospital.

Timeline	Type of Assessment
Emergency Department (ED)	
Patient arrives in acute respiratory distress.	Perform emergency assessment (see Table 69-3).
Problem is identified and critical interventions are performed; patient stabilizes.	Conduct a focused assessment of the respiratory and related body systems (e.g., cardiovascular). May begin comprehensive assessment of all body systems.
Clinical Unit	
Patient is admitted to a monitored clinical unit.	Complete comprehensive assessment of all body systems within proper timeframe.
Reassess throughout shift. New nurse arrives at change of shift.	Perform focused assessment of respiratory system and other related body systems (to determine if new problems have arisen).

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The patient health history and physical examination provide the nurse with information to primarily
   - **a.** diagnose a medical problem.
   - **b.** investigate a patient's signs and symptoms.
   - **c.** classify subjective and objective patient data.
   - **d.** identify nursing diagnoses and collaborative problems.
2. The nurse would place information about the patient's concern that his illness is threatening his job security in which functional health pattern?
   - **a.** Role-relationship
   - **b.** Cognitive-perceptual
   - **c.** Coping–stress tolerance
   - **d.** Health perception–health management
3. The nurse is preparing to examine a patient's abdomen. Identify the proper order of the steps in the assessment of the abdomen, using the numbers 1-4 with 1 = the first technique and 4 = the last technique:
   ___Inspection
   ___Palpation
   ___Percussion
   ___Auscultation
4. Which situation would require the nurse to obtain a focused assessment *(select all that apply)*?
   - **a.** A patient denies a current health problem.
   - **b.** A patient reports a new symptom during rounds.
   - **c.** A previously identified problem needs reassessment.
   - **d.** A baseline health maintenance examination is required.
   - **e.** An emergency problem is identified during physical examination.

1. d, 2. a, 3. 1, 4, 3, 2, 4. b, c.

LEARNING OUTCOMES

1. Prioritize patient teaching goals for diverse patients and caregivers.
2. Analyze teaching implications related to the diverse needs of adult learners.
3. Apply strategies to manage challenges to nurse-teacher effectiveness.
4. Evaluate the role of the caregiver in patient teaching.
5. Apply the teaching-learning process to diverse patient populations.
6. Relate the physical, psychologic, and sociocultural characteristics of the patient and caregiver to the teaching-learning process.
7. Select appropriate teaching strategies for diverse patient populations.
8. Select appropriate methods to evaluate patient and caregiver teaching.

This chapter describes the process of patient and caregiver teaching. In addition, it discusses the strategies and methods that contribute to successful teaching and learning experiences.

ROLE OF PATIENT AND CAREGIVER TEACHING

Patient and caregiver (family member or significant other) teaching is an interactive and dynamic process that involves a change in a patient's knowledge, behavior, and/or attitude to maintain or improve health. You will find that teaching is one of your most challenging and rewarding roles. Teaching patients is a key nursing intervention that makes a difference in their lives.

General goals of patient teaching include health promotion, prevention of disease, management of illness, and appropriate selection and use of treatment options. In patients with acute and chronic health problems, teaching can prevent complications and promote recovery, self-care, and independence. Seventy percent of the deaths in the United States are due to chronic illnesses, illnesses with which patients often live for many years.[1] Whether patients adequately manage their health problems and maintain quality of life depends on what they learn about their conditions and what they choose to do with this knowledge. Patients who understand their discharge teaching, including how to take their medicines and when to follow-up with their health care providers, are 30% less likely to be readmitted or visit the emergency department than patients who did not receive this information.[2]

Teaching may occur wherever you work. Although institutions may employ advanced practice nurses and patient educators to establish and oversee patient teaching programs, you

Denise Neill, RN, PhD, CNE, Assistant Professor and RN-BSN and MSN Program Coordinator, University of Houston–Victoria, Victoria, Texas.

are always responsible for patient and caregiver teaching.[3-5] It is a responsibility that cannot be delegated to unlicensed assistive personnel.

Every interaction with a patient and a caregiver is a potential *teachable moment*. On any given day, more informal opportunities to teach will occur than formal opportunities. Take advantage of all of these moments. For example, when you teach a patient with asthma how to use a peak flow meter, you do not require a formal teaching plan. However, when your patient has a specific learning need about health promotion or management of a health problem, you should develop a teaching plan. A **teaching plan** includes (1) assessment of the patient's ability, need, and readiness to learn; and (2) identification of problems that can be resolved with teaching. Then develop goals with the patient, provide teaching interventions, and evaluate the effectiveness of the teaching.

TEACHING-LEARNING PROCESS

Teaching is not just imparting information. **Teaching** is a process of deliberately arranging conditions to promote learning that results in a change in behavior.[6] Teaching can be a planned or informal experience. It uses a combination of methods such as instruction, counseling, and behavior modification.

Learning is acquiring knowledge and/or skills. It can result in a permanent change in a person.[6] Observation of this change is an indication that learning has occurred. Learning may also result in a potential or capability to change behavior. This is seen in a patient who understands the instruction and is fully informed, but chooses not to change behavior. In this case, teaching gives the patient the capability to make a decision to change behavior, but the decision is the patient's.

Although learning may occur without teaching, teaching helps to organize information and skills to make learning more efficient. In patient teaching the teaching-learning process involves the patient, the patient's caregiver(s), and you.

Adult Learner

Adult Learning Principles. Understanding how and why adults learn is important for you to effectively teach patients and their caregivers. Many of the theories of adult learning have risen from the work of Malcolm Knowles, who identified six principles of *andragogy* (adult learning) that are important for you to consider when teaching adults[7] (Table 4-1).

Models to Promote Health. When a change in health behaviors is recommended, patients and their caregivers may progress through a series of steps before they are willing or able to accept the change. Prochaska and Velicer proposed six stages of change in their *Transtheoretical Model of Health Behavior Change*[8] (Table 4-2). This model is frequently used to help patients stop smoking, manage diabetes, and lose weight.

Motivational interviewing (see *www.motivationalinterview.org*) uses nonconfrontational interpersonal communication techniques to motivate patients to change behavior.[9] This strategy includes the use of any intervention that enhances the

TABLE 4-1 ADULT LEARNING PRINCIPLES APPLIED TO PATIENT AND CAREGIVER TEACHING

Principles	Teaching Implications for the Nurse	Examples
The learner's need to know	• Patients need to know why they should learn something, what they need to learn, and how it will benefit them. • Ask the patient questions such as, "What do you think you need to learn about this topic?"	Your patient and his caregiver have requested specific information on exercise guidelines after a heart attack.
The learner's readiness to learn	• Readiness and motivation to learn are high when facing new tasks. • Health crises provide opportunities for patients to learn and change behavior. • Stress and anxiety may interfere with learning, thus requiring frequent reinforcement of content.	While recovering from a transient ischemic attack, your patient tells you that she is ready to learn about the changes she needs to take to reduce her risk for stroke.
The learner's prior experiences	• Motivation is increased when patients already know something about the subject from past experiences. • Identification of past knowledge and experiences can help find familiar ground to increase patients' confidence.	Your patient needs to begin injections of enoxaparin (Lovenox). She tells you that she gives her father insulin injections and is ready to learn how to administer this medication.
The learner's motivation to learn	• Patients prefer to apply learning immediately. • Long-term goals may have less appeal than short-term goals. • Focus teaching on information that the patient views as being needed right now.	Your patient is scheduled to be discharged in the morning. Both she and her caregiver have received instruction on wound care and have watched the procedure. The caregiver tells you that he wants to perform the wound care this evening.
The learner's orientation to learning	• Patients seek out various resources for specific learning and prefer to have choices. • When the patient does not recognize the relevancy of the teaching, offer explanations of the value of the learning. • Teaching should target the specific problem or circumstance.	Your patient, who is newly diagnosed with diabetes mellitus, tells you that he is worried about the diet changes he will need to make. Share several options with him to learn about diet changes (e.g., cooking classes, Internet-based tutorials, individual sessions with the dietitian, brochures).
The learner's self-concept	• Patients need control and self-direction (sense of autonomy) to maintain their sense of self-worth. • Patients do not learn when they are treated like children and told what they must do.	Your patient has a temporary colostomy. She says she is not ready to look at the stoma. Work out a schedule with her for learning colostomy care that meets her need for control and prepares her for self-care.

TABLE 4-2 STAGES OF CHANGE IN TRANSTHEORETICAL MODEL

Stage	Patient Behavior	Nursing Implications
1. Precontemplation	Is not considering a change. Is not ready to learn.	Provide support, increase awareness of condition. Describe benefits of change and risks of not changing.
2. Contemplation	Thinks about a change. May verbalize recognition of need to change; says "I know I should," but identifies barriers.	Introduce what is involved in changing the behavior. Reinforce the stated need to change.
3. Preparation	Starts planning the change, gathers information, sets a date to initiate change, shares decision to change with others.	Reinforce the positive outcomes of change, provide information and encouragement, develop a plan, help set priorities, and identify sources of support.
4. Action	Begins to change behavior through practice. Tentative and may experience relapses.	Reinforce behavior with reward, encourage self-reward, discuss choices to help minimize relapses and regain focus. Help patient plan to deal with potential relapses.
5. Maintenance	Practices the behavior regularly. Able to sustain the change.	Continue to reinforce behavior. Provide additional teaching on the need to maintain change.
6. Termination	Change has become part of lifestyle. Behavior no longer considered a change.	Evaluate effectiveness of the new behavior. No further intervention needed.

Adapted from Prochaska J, Velicer W: The transtheoretical model of health behavior change, *Am J Health Promot* 12:38, 1997. (Classic)

patient's motivation for change (Table 4-3). The techniques used in motivational interviewing are linked to the stages of change as identified by Prochaska and Velicer.

During the process of change, relapse and recycling through the stages are expected. Sometimes patients do not change behaviors or return to previous behaviors after a period of change. This may indicate that the interventions used did not consider the patient's stage of change.[10] Identify the patient's current stage of readiness for change and the stage to which the patient is moving. Patients who are in the early stages of change need and use different kinds of motivational support than patients at later stages of change.

For example, a patient who smokes cigarettes who is hospitalized is often in the *precontemplation* or *contemplation* stage of change. In the precontemplation stage, patients are not concerned about their substance use and are not considering changing their behavior. During this stage, help the patient increase awareness of risks and problems related to smoking and create doubt about the use of cigarettes. Ask the patient what he or she thinks could happen if the behavior is continued, provide evidence of the problem (e.g., x-ray changes), and offer factual information about the risks of smoking. Although patients may not be ready to change behavior while experiencing an acute health problem, the seeds of doubt are sown. In other cases, such as when a patient experiences a life-threatening condition (e.g., heart attack), there may be an immediate awareness of the problem and motivation to change.

TABLE 4-3 KEY ASPECTS OF MOTIVATIONAL INTERVIEWING

- Listen rather than tell.
- Adjust to, rather than oppose, patient resistance.
- Express empathy through reflective listening.
- Focus on the positive. Do not criticize the patient.
- Gently persuade with the understanding that change is up to the patient.
- Focus on the patient's strengths to support the hope and optimism needed to make changes.
- Avoid argument and direct confrontation, which can cause defensiveness and a power struggle.
- Help the patient recognize the "gap" between where he or she is and where he or she hopes to be.

A patient in the *contemplation* stage of change often experiences ambivalence. The patient understands that the behavior is a problem and that change is necessary. However, he or she believes that change is too difficult or that the pleasures of the behavior are worth the risks. This is seen in the patient who says, "I know that I have to stop smoking. This heart attack really scared me. I know I need to lose weight and start exercising, but I can't change everything all at once. Smoking helps me control my eating—I can't stop until I lose some weight." During this stage of change, help the patient consider the positive and negative aspects of his or her behavior (e.g., substance use), gently trying to tip the balance in favor of positive behavior. Helping the patient discover internal motivators in addition to those external motivators (e.g., second heart attack, lung disease) that push the patient toward change can move the patient from contemplating change to preparation and action. Throughout this process, emphasize the patient's personal choices and responsibilities for change.

As the patient moves from contemplation to *preparation,* a commitment to change is strengthened by helping the patient develop **self-efficacy,** which is the belief that one can succeed in a given situation. In this case it is the patient's belief that substance-use behaviors can be changed. Support even the smallest effort to change. Movement through action and maintenance stages of change requires continued support to increase the patient's involvement and participation in treatment. A comprehensive discussion of motivational interviewing is presented in the Treatment Improvement Protocols available at *www.ncbi.nlm.nih.gov/books/NBK14856*.

The resolution of acute health problems or discharge from the hospital often occurs before the patient moves to the preparation and action stages of change. As the patient develops readiness to change in the contemplative stage of change, continue to support him or her with referral to appropriate community and outpatient resources.

Nurse as Teacher

Required Competencies

Knowledge of Subject Matter. Although it is impossible to be an expert in all subject areas, develop confidence as a teacher by becoming knowledgeable about the subject to be taught. Information can be obtained through reliable sources such as journals and books. For example, if you are teaching patients about the management of hypertension, you must be able to explain what hypertension is and why it is important to treat it. Also teach patients what they need to know about exercise, diet, and side effects of medications. Teach the patient and the caregiver how to use blood pressure (BP) equipment to monitor BP and to identify situations that need to be reported to health care providers. Finally, provide the patient with additional resources, such as written brochures, appropriate websites, and information about support organizations (e.g., American Heart Association).

Sometimes you will not be able to answer patients' or caregivers' questions. Clarifying their questions may help if you are unsure of what they are asking. When it is apparent that you do not have the knowledge to answer the question, admit this to the patient and caregiver and seek help from co-workers, patient educators, and other reliable sources.

Communication Skills. Patient teaching depends on effective communication between you and the patient or caregiver. *Medical jargon* is intimidating and frightening to most patients and their caregivers. Introduce medical words with definitions of their meaning. Consider carefully before using acronyms (e.g., CABG for coronary artery bypass graft) and abbreviations (e.g., IV) when talking with patients. Have the patient and caregiver clarify their understanding of the disease process. Have them explain what they know in their own words. For example, if a patient is told that he has leukopenia, explain this diagnosis in words that mean something to him. Use word roots, explaining that *leuko* refers to a leukocyte, a white blood cell that fights infections, and that *penia* means deficiency or shortage. To enhance learning, use a brief explanation such as, "You have a shortage of white blood cells, the cells that fight infection."

Nonverbal communication is critical when teaching. Nonverbal communication is often guided by cultural practices. For example, in Western culture, sitting in an open, relaxed position facing the patient with eyes at the same level delivers a positive, nonverbal message (Fig. 4-1). In a hospital setting this may require raising the patient's bed or sitting in a chair at the bedside. Open body gestures communicate interest and a willingness to share. With patients from Eastern cultures, you may need to avoid direct eye contact and provide health information to a family spokesperson rather than directly to the patient.

Also develop the art of *active listening* by paying attention to what is said, observing the patient's nonverbal cues, and not interrupting. Nod in response to the patient's statements and rephrase and reflect what the patient is saying to help clarify communication.

Empathy is the courage to enter into the world of another in a manner that does not judge or correct but where understanding is the goal. Empathy means putting aside your own self and stepping into the patient's shoes. When combined with the skill of empathy, active listening is a powerful way to communicate caring and prepare the patient to learn.

Challenges to Nurse-Teacher Effectiveness. Teaching patients and caregivers has many challenges, including (1) lack of time, (2) your own feelings as a teacher, (3) nurse-patient differences in learning goals, and (4) early discharge from the health care system.

FIG. 4-1 Open, relaxed positioning of patient, spouse, and nurse at eye level promotes communication in teaching and learning. (Jupiterimages/Photos.com/Thinkstock.)

Lack of time can be a barrier to effective teaching. For example, the patient's physical needs may compete for time that could be used for teaching. To make the most of limited time, it is critical to set learning priorities with the patient. Tell the patient at the beginning of the interaction how much time you can devote to the session. Teaching can be delivered or reinforced during every contact with the patient or caregiver. For example, when giving medications, explain the purpose and side effects of each drug. Reinforcing small pieces of information over time is an effective teaching strategy, especially if information is new or complex.

Additional barriers are your *own feelings as a teacher* and insecurity about your own knowledge and competence. Teaching is a skill that takes time to master. Become familiar with the various resources for patient teaching that are available at your agency. Consult with nurse educators for further help with developing your teaching skills.

Also, disagreements can arise among the patient, the caregiver, and you regarding the expectations or outcomes of teaching. Having realistic discussions about discharge plans, identifying timelines, and exploring home care options can bring urgency to the teaching situation. For example, after a diagnosis of chronic heart failure as a result of aortic valve insufficiency and subsequent emergent valve surgery, the patient and the caregiver may reject teaching efforts until they accept and realize the seriousness of the patient's health problem.

Finally, another important challenge to patient teaching relates to patients having early and quick discharges from the health care system. Shortened lengths of hospital stays and hurried outpatient clinic visits have resulted in patients only having basic teaching plans implemented.

Caregiver Support in the Teaching-Learning Process

The teaching and learning process is applicable to the caregiver as well as the patient. **Caregivers** are people who care for those who cannot care for themselves. Most common, caregivers are family members or significant others who (1) give or assist with direct patient care; (2) provide emotional, social, spiritual, and possibly financial support for the patient; and (3) manage and coordinate health care services.

Approximately one in four American adults provides care to someone on a daily basis. Caregivers are often categorized by their relationship to the patient. The most common types of caregivers are spouses, adult children, parents, grandparents, and life partners. Although older adult women are the most common family caregivers, other examples include husbands who care for wives with Alzheimer's disease, adult children who care for a parent with a stroke, grandparents who care for a grandchild with a developmental disorder, parents who care for an adult child with a spinal cord injury, and life partners who care for loved ones with a variety of health problems.[11]

Identify the key caregiver(s) for the patient. Assess the caregiver's roles and relationships to the patient. The patient's health problem affects family roles and functions. Identify the needs of caregivers, whether it is in the acute care setting, during the transition to home, or in a home setting[12] (Table 4-4).

Consider cultural differences when assessing the caregiver. In some cultures a male family member may be the designated spokesperson. This person would receive and communicate information among family members and the patient. In planning for discharge to home, it is important to include caregivers who will actually provide the care for the patient, along with the family spokesperson.[12]

As much as possible, teach the caregiver along with the patient. Explain the goals of the teaching plan clearly to both of them. Caregivers may need assistance to learn the physical and technical requirements of care, find resources for home care, locate equipment and supplies, and rearrange the home environment to accommodate the patient. Sources of support for the transition from hospital to home include community-based agencies, Medicare and Medicaid offices, and case managers at the hospital and insurance companies.[13] Patients and caregivers may have different teaching needs. For example, the first priority of an older diabetic patient with a large leg ulcer may be to learn how to transfer from a bed to a chair in the least painful manner. On the other hand, the caregiver may be most concerned about learning the technique for dressing changes. Both the patient's and the caregiver's learning needs are important. The patient and the caregiver may also have differing or conflicting views of the illness and treatment options. Developing a successful teaching plan requires you to view the patient's needs within the context of the caregiver's needs. For instance, you may teach a patient with right-sided *paresis* (weakness) self-feeding techniques with special implements, but at a home visit you find the patient being fed by the caregiver. On questioning, the caregiver reveals that it is too difficult to watch the patient struggle with feeding, it takes too long, and it is messy. As a result, the caregiver decides that it is easier to just feed the patient. This is an example of a situation in which both the patient and caregiver need additional teaching about the goals of self-care.

Finally, discuss the potential that support groups, networks of family and friends, and community resources have for providing ongoing support and continuing education. Support groups help by sharing experiences and information, offering understanding and acceptance, and suggesting solutions to common problems and concerns. Encourage the caregiver to seek help from the formal social support system on matters such as housing, health coverage, finances, and respite care. Respite care, which is planned temporary care for the patient, includes adult day care, in-home care, and assisted living services.

Caregiver Stress. Caregiver responsibilities are usually taken on gradually with the progression of the patient's illness. As the caregiving responsibilities become more demanding, caregivers often realize that their lives have changed because of this experience. Overwhelmingly, caregivers want to continue their usual activities (e.g., work) despite the hardships they face in caring for acute and chronically ill patients.[14,15]

Prolonged periods of caregiving coupled with a patient's life-limiting illness can contribute to stress and burnout. Some common caregiver stressors are listed in Table 4-5. As caregiving progresses, stressors may change. For example, a caregiver may initially need only to adjust work schedules to accommodate a patient's health care appointments. Later, as the patient's condition worsens, the caregiver may have to reduce work hours, incurring financial hardships.

Caregiving is an experience for which most people are not prepared. It is common for caregivers to become physically, emotionally, and economically overwhelmed by the responsibilities and demands of caring for a family member. The stress of caregiving may result in emotional problems such as depression, anger, and resentment. Signs of caregiver stress include irritability, inability to concentrate, fatigue, and sleeplessness. The caregiver often experiences decreased social interactions and may be at risk for social isolation. Multiple commitments, fatigue, and, at times, the patient's socially inappropriate behaviors contribute to the caregiver's social isolation. Stress can progress to burnout and result in negligence and abuse of the

TABLE 4-4 ASSESSMENT OF CAREGIVER NEEDS

Assess caregivers using the following questions:

1. How are you coping with your caregiver role?
2. Do you have any difficulties performing your caregiver responsibilities?
3. How much support do you get from outside sources (e.g., other family members, friends)?
4. Are you aware of and do you use community resources (e.g., disease-specific professional organizations [such as Alzheimer's Association, American Heart Association], adult day care centers, church, synagogue)?
5. Do you know about resources that are available for respite (someone caring for your loved one while you have time to yourself)?
6. What kind of help or services do you need now and in the near future?
7. How can I or other health care professionals help you in your caregiving role?

TABLE 4-5 CAREGIVER STRESSORS

- Change in roles and relationships within family unit
- Lack of respite or relief from caregiving responsibilities
- Need to juggle day-to-day activities, decisions, and caregiving
- Change in living conditions to accommodate family member
- Conflict in the family unit related to decisions about caregiving
- Other people's lack of understanding of the time and energy needed for caregiving
- Inability to meet personal self-care needs, such as socialization, sleep, eating, exercise, and rest
- Financial depletion of resources as a result of a caregiver's inability to work and the increased cost of health care
- Inadequate information or skills related to specific caregiving tasks, such as bathing, drug administration, wound care

patient by the caregiver. See Chapter 5 for information on elder mistreatment and abuse.

In the family system an illness experienced by one family member affects the entire family and alters family interactions. Often family members do not communicate with each other about the patient's needs, and this results in tension. Family conflicts regarding how patient care should be given can lead to disagreements and conflict within the family.

At the same time, many family members involved in direct caregiver activities also identify rewards associated with this role. Positive aspects of caregiving include (1) knowing that their loved one is receiving good care (often in a home environment), (2) learning and mastering new skills, and (3) finding opportunities for intimacy. The tasks involved in caregiving often provide opportunities for family members to gain greater insights into each other and strengthen their relationships.

Encourage caregivers to take care of themselves.[16] Suggest journaling or joining a support group (also available online) to help them share feelings that may be difficult to express. Remind caregivers that getting regular exercise and eating balanced meals at regular times will enhance their well-being. Encourage contact with others to provide emotional support. Finally, humor is important, and sometimes its use by caregivers can provide distraction and relieve stress-filled situations.

Regulatory Mandates for Patient Teaching

Several important agencies have provided specific mandates related to teaching hospitalized patients. The Joint Commission's (TJC's) accreditation standards, National Patient Safety Goals,[3] and the American Hospital Association's Patient Care Partnership[17] clearly state that patients have a fundamental right to receive written information about their care. This information includes their diagnosis, treatment, and prognosis in terms that they can reasonably be expected to understand. For example, this means that written materials must be appropriate for the patient's reading level. One program initiated by TJC, called Speak Up, was developed to encourage patients to become more involved and informed about their plan of care[18] (Table 4-6). Another program proposed by the National Patient Safety Foundation is called **Ask Me 3**.[19] A variety of resources that prompt patients to ask specific questions about their care are available as a part of these initiatives *(www.jointcommission.org/speakup.aspx, www.npsf.org/for-healthcare-professionals/programs/ask-me-3)*.

TABLE 4-6 THE JOINT COMMISSION'S SPEAK UP™ INITIATIVE

Speak up if you have questions or concerns. If you still do not understand, ask again. It is your body and you have a right to know.
Pay attention to the care you get. Always make sure you are getting the right treatments and medicines by the right health care professionals. Do not assume anything.
Educate yourself about your illness. Learn about the medical tests you get and your treatment plan.
Ask a trusted family member or friend to be your advocate (advisor or supporter).
Know what medicines you take and why you take them. Medicine errors are the most common health care mistakes.
Use a hospital, clinic, surgery center, or other type of health care organization that has been carefully checked out.
Participate in all decisions about your treatment. You are the center of the health care team.

Source: The Joint Commission: To prevent health care errors, patients are urged to Speak Up (poster). Retrieved from *http://www.jointcommission.org/assets/1/18/SpeakUp_Poster.pdf*.

PROCESS OF PATIENT TEACHING

Many different models and approaches are used in the process of patient teaching. However, the approach used most frequently by nurses parallels the nursing process. The **teaching process** and the nursing process both involve the development of a plan that includes assessment, setting of patient goals or outcomes, intervention, and evaluation. The teaching process, like the nursing process, may not always flow in sequential order, but the steps serve as checkpoints.

Assessment

During the general nursing assessment, gather data to determine if the patient has learning needs. For example, what does the patient know about the health problem? How does he or she perceive the problem? If a learning need is identified, a more detailed assessment is needed, and that problem is addressed with the teaching plan. Assessment also includes the caregivers to determine their role and ability to care for the patient at home.[12] Key questions to use in the assessment are included in Table 4-7.

Physical Factors. The patient's age is an important factor to consider in the teaching plan. Age affects the patient's experiences, rate of learning, and ability to retain information.[20] The effects of increased age may be obvious, but the inexperience of younger individuals can also affect learning. For example, a man in his twenties who has never thought about his own mortality may be unable to accept the long-term health implications of diabetes mellitus.

Sensory impairments (e.g., hearing or vision loss) decrease sensory input and can alter learning. Magnifying glasses, bright lighting, and materials printed in a large font may help the patient with impaired vision read teaching materials. Hearing loss can be helped with hearing aids and teaching techniques that use more visual stimuli. Cognitive function may be affected by disorders of the nervous system, such as stroke and head trauma, and also by other diseases, such as liver impairment and heart failure. Patients with alterations in cognitive function may have difficulty learning and may require greater caregiver involvement in the teaching process. Manual dexterity is needed to perform procedures such as self-administration of injections or BP monitoring. Problems performing manual procedures might be resolved by using adaptive equipment.

Pain, fatigue, and certain medications also influence the patient's ability to learn. No one can learn effectively when in pain. When the patient is experiencing pain, provide only brief explanations and follow up with more detailed instruction when the pain has been managed. A fatigued and weakened patient cannot learn effectively because of the inability to concentrate. Sleep disruption is common during hospitalization, and patients are frequently exhausted at the time of discharge. Drugs that cause central nervous system depression, such as opioids and sedatives, cause a general decrease in mental alertness and can affect the patient's ability to learn new information. Adjust the teaching plan to accommodate these factors by setting high-priority goals based on need-to-know information and realistic expectations. The patient may need a referral for follow-up teaching so that learning is continued and reinforced after discharge.

TABLE 4-7 ASSESSMENT OF FACTORS AFFECTING PATIENT TEACHING

Factors and Key Questions

Physical
- What is the patient's age and gender?
- Is the patient acutely ill?
- Is the patient fatigued or in pain?
- What is the primary diagnosis?
- Are there additional medical problems?
- What is the patient's current mental status?
- What is the patient's hearing ability? Visual ability? Motor ability?
- What drugs does the patient take that may affect learning?

Psychologic
- Does the patient appear anxious, afraid, depressed, defensive?
- Is the patient in a state of denial?
- What is the patient's level of motivation? Self-efficacy?

Sociocultural
- What are the patient's beliefs regarding his or her illness or treatment?
- Is proposed teaching consistent with the patient's cultural values?
- What is the patient's educational experience, reading ability, primary language?
- What is the patient's present or past occupation?
- How does the patient describe his or her financial status?
- What is the patient's living arrangement?
- Does the patient have family or close friends?

Learner
- What does the patient already know?
- What does the patient think is most important to learn first?
- What prior learning experiences establish a frame of reference for current learning needs?
- What has the patient's health care provider told the patient about the health problem?
- Is the patient ready to change behavior or learn?
- Can the patient identify behaviors and habits that would make the problem better or worse?
- How does the patient learn best? Through reading, listening, doing things?
- In what kind of environment does the patient learn best? Formal classroom? Informal setting, such as home or office? Alone or among peers?
- In what way should the caregiver(s) be involved in patient teaching?

Psychologic Factors. Psychologic factors have a major influence in the patient's ability to learn. Anxiety and depression are common reactions to illness. Although mild anxiety increases the learner's perceptual and learning abilities, moderate or severe anxiety limits learning. Both anxiety and depression can negatively affect the patient's motivation and readiness to learn. For instance, the patient newly diagnosed with diabetes mellitus who is depressed about the diagnosis may not listen or respond to instructions about blood glucose testing. Discussions with the patient about these concerns or referrals to an appropriate support group may enable the patient to learn that management of diabetes is possible.

Patients also respond to the stress of illness with a variety of defense mechanisms such as denial, rationalization, or even humor. A patient who denies having cancer will not be receptive to information related to treatment options. Similarly, a caregiver may have difficulty accepting a terminal diagnosis. A patient using rationalization will imagine any number of reasons for avoiding change or for rejecting instruction. For example, a patient with heart disease who does not want to change dietary habits will relate stories of people who have eaten bacon and eggs every morning and lived to be 100. Some patients also use humor to filter reality or decrease anxiety. They may use laughter to escape from the experience of facing threatening situations. Humor in the teaching process is important and useful, but determine when humor is used excessively or inappropriately to avoid reality.

One important determinant of successful adoption of new behaviors is the patient's sense of self-efficacy. There is a strong relationship between self-efficacy and outcomes of illness management.[21,22] Self-efficacy increases when a person gains new skills in managing a threatening situation, but decreases when the individual experiences repeated failure, especially early in the course of events. Plan easily attainable goals early in the teaching sessions. Proceed from simple to more complex content to establish a feeling of success.

Sociocultural Factors

Health Literacy. *Literacy* is the ability to use printed and written information to function in society. The recent focus on the literacy rates of the U.S. population and their effects on health and health care have major implications for patient and caregiver teaching. The most recent national literacy survey reported that 43% of the general population and 66% of people older than 60 have basic to below basic literacy skills, and another 5% are nonliterate in English.[4] Assessment of literacy is challenging, since patients rarely admit they have difficulty reading because of feelings of inadequacy and low self-esteem.[23]

Health literacy is the degree to which individuals have the capacity to obtain and understand basic health information needed to make appropriate health decisions.[3] Patients with limited literacy have trouble understanding and acting on health information, leading to health illiteracy. Even patients with higher general literacy can have low health literacy when trying to understand complex health information. Health illiteracy results in poor patient outcomes, nonadherence with treatment plans, limited self-management skills, and increased health disparities.[24]

Easy-to-use assessment tools are available to determine a patient's health literacy. The Single-Item Literacy Screener (SILS) uses one question to identify adults who need help with reading.[25] The question is, "How often do you need to have someone help you when you read instructions, pamphlets, or other written material from your doctor or pharmacy?"

Patient teaching materials should be written at the fifth-grade or lower reading level.[23-25] TJC has established that patient teaching should be tailored to the patient's literacy needs. For example, patients should be taught in their primary language. This is accomplished using medical interpreters (translators)[26] (Fig. 4-2). (Medical interpreters are discussed in Chapter 2 on pp. 32 to 33.) Many patient teaching materials are currently available in languages other than English.

Cultural Considerations. Learning is influenced by the wider culture to which a patient belongs. Health practices, beliefs, and behavior are influenced by one's cultural traditions. These traditions, which can affect patient teaching, can be identified in a cultural assessment (see Table 2-7). TJC requires that patient teaching be tailored to the patient's cultural needs.[26] To prevent stereotyping patients, it is important to simply ask if there is a cultural group with which the patient identifies. Ask patients to describe their beliefs regarding health and illness.

FIG. 4-2 Nurse communicating with a non-English-speaking patient using a translation phone service.

One cultural element that specifically affects the teaching-learning process is a conflict between the patient's cultural beliefs and values and the behaviors promoted by the health care team. For example, a patient who values a trim figure can be taught to use diet and exercise to retain that figure while at the same time improving BP control. However, in another patient's culture, being heavier may be valued as a sign of financial success and sexuality. This patient may have more difficulty accepting the need for diet and exercise unless the importance of BP control is understood.

Also assess the patient's use of cultural remedies and folk healers. For teaching to be effective, incorporate cultural health practices into the teaching plan. Also consider the cultural remedies that may interfere with or are contraindicated by the treatment plan.

In addition, it is important to know who has authority in the patient's culture. The patient may defer to the authority, such as an elder or a spiritual leader, for decisions. In this case, identify and work with the decision makers in the patient's cultural group. (See Chapter 2 for more information on cultural competence.)

Socioeconomic Considerations. A variety of socioeconomic factors are considered when preparing to teach patients. Knowing the patient's present or past occupation may assist you in determining the vocabulary to use during teaching. For example, an auto mechanic might understand the volume overload associated with heart failure as flooding an engine. An engineer may understand the principles of physics associated with gravity and pressures when discussing vascular problems.

Ask the patient about living arrangements. Whether the patient lives alone, with friends, or with family will influence who is included in the teaching process. You may need to modify the teaching plan if the patient does not have access to electricity or phones. If the patient has unmet learning needs by the time of discharge, arrange for continued teaching after discharge.

Learner Factors. Finally, assess learner factors, including the patient's learning needs, readiness to learn, and learning style.

Learning Needs. **Learning needs** are the new knowledge and skills that an individual must have to meet a goal. The assessment of learning needs should first determine what the patient already knows, whether the patient has misinformation, and any past experiences with health problems. Patients with long-standing health problems may have different learning needs from those patients with newly diagnosed health problems.

What a patient should learn about managing an illness or what behaviors need to be changed to promote health may seem obvious to you. However, what you think is important may be different from what patients want to know. Remember that adults learn best when the teaching provides information that they view as being needed immediately (see Table 4-1). Ask patients to prioritize what they see as the most critical information. For example, give the patient a list of the recommended topics to choose from. Also ask the patient to identify other topics not on the list. Having patients prioritize their own learning needs allows you to begin with the patient's most important needs. When information regarding life-threatening complications is needed, promote the priority of learning this content by explaining why the information is "need to know." Tailor your teaching to meet your patient's individual learning needs, especially when time is limited.

Readiness to Learn. Readiness to learn and motivation depend on multiple factors, such as perceived need, attitudes, and beliefs. When teaching adults, identify what information the person values. Readiness to learn is increased if the patient perceives a need for information, has a belief that a behavior change has value, or perceives the learning activities as new and stimulating.[27]

Before implementing the teaching plan, determine where the patient is in the stages of change process (see Table 4-2). If the patient is only in the precontemplation stage, just provide support and increase the patient's awareness of the problem until the patient is ready to consider a change in behavior. Nurses in outpatient settings and home health care can continue to evaluate the patient's readiness to learn and implement the teaching plan as the patient moves through the stages of change. Reinforcement is a strong motivational factor for achieving a desired behavior and needs to be incorporated throughout the change process. **Positive reinforcement** involves rewarding the target behavior with positive feedback or other rewards to maintain the behavior.[8]

Learning Style. Each person has a distinct style of learning that is as individual as his or her personality. The three general learning styles are (1) *visual* (reading, pictures), (2) *auditory* (listening), and (3) *physical* (doing things). People often use more than one learning style to acquire new information or skills. To assess a patient's learning style, ask how the patient prefers to learn and how the patient has learned in the past.[28] During assessment of the patient's learning style, identify the patient who does not read or who has limited health literacy. For example, the patient may tell you that he or she does not read much, but likes to learn from television programs. If possible, always use auditory and visual methods (e.g., CDs/DVDs) when patients specifically identify them as preferred methods of learning.

Planning

Prioritize the patient's learning needs and agree on learning goals. If the patient's physical or psychologic condition interferes with his or her participation, the patient's caregiver(s) can assist you in the planning phase.

Setting Goals. It is important to write clear, attainable, and measurable learning objectives or goals. Learning goals relate to the intended outcome of the learning process, guide the selection of teaching strategies, and help evaluate the patient's progress. Learning goals are parallel to patient outcomes in the nursing care plan (NCP). Many settings provide standardized NCPs that contain preset goals and interventions for specific learning needs. Modify these NCPs based on the patient's unique sociocultural and learner characteristics.

Standardized teaching plans are often included in care management guides and clinical practice guidelines. Standardized teaching plans frequently contain evidence-based information and skills that a patient and caregiver need to know concerning a specific health problem or procedure. However, as with NCPs, individualize these plans to meet the patient's specific needs. (See eFig. 4-1, eFig. 4-2, and eTable 4-1 on the website for this chapter for information on writing objectives or goals and examples of standardized teaching plans.)

EVIDENCE-BASED PRACTICE

Translating Research Into Practice

Are Decision Aids Helpful in Making Decisions About Health Care?

Clinical Question

For patients (P) with treatment and screening decisions, what is the effect of decision aids (I) versus usual teaching interventions (C) on outcomes associated with decisions about health care (O)?

Best Available Evidence

Systematic review of randomized controlled trials (RCTs).

Critical Appraisal and Synthesis of Evidence

- 86 RCTs ($n = 20,209$) of adults comparing use of decision aids versus usual care interventions on decision making attributes and behavioral outcomes.
- Decision aids provide information about treatment or screening options that may be valued differently by patients. Aids may be pamphlets, videos, or Internet-based tools.
- Knowledge, decisional conflict, patient-provider communication, and effect on behavior and health care system were measured.
- Decision aids significantly improved knowledge; reduced patient passivity and feelings of being uninformed; positively affected patient-provider communication; and reduced patient elective choices for invasive surgery, prostate specific antigen (PSA) screening, and menopausal hormone usage.

Conclusion

- Decision aids are valuable in helping patients decide among various treatments and screening options.

Implications for Nursing Practice

- Provide decision-making aids and collaboratively engage in communication with patients who face choices in treatment and screening.
- Involve patients in the decision-making process by sharing realistic perceptions of benefits and harms of options.
- Clarify with patients their personal values when exploring health care choices.

Reference for Evidence

Stacy D, Bennett C, Barry M, et al: Decision aids for people facing health treatment or screening decisions, *Cochrane Database Syst Rev* 10: CD00143, 2011.

P, Patient population of interest; *I,* intervention or area of interest; *C,* comparison of interest or comparison group; *O,* outcomes of interest; *T,* timing (see p. 12).

Selecting Teaching Strategies. Three factors that determine teaching strategies are (1) patient characteristics (e.g., age, educational background, culture, language skills), (2) subject matter, and (3) available resources. Table 4-8 provides a summary of the various learner characteristics and recommended teaching strategies based on the generation of the patient or caregiver.[29,30]

Various teaching strategies are used to enhance learning (Table 4-9). Frequently, several teaching strategies are used together (Fig. 4-3). Discussion is the most common type of interaction used in teaching patients and caregivers. Another type of group teaching involves *peer teaching*, as found in support groups. Patients dealing with common problems such as cancer, alcoholism, and eating disorders can benefit from peer teaching.

Learning Materials. Use learning materials that are provided in multiple formats (see Table 4-9). To use this strategy, know what materials are available within the facility, from support agencies, and from professional groups. The use of CDs/DVDs is extremely beneficial, particularly when teaching content that is largely visual, such as the steps of a procedure (e.g., suctioning a tracheostomy). The health care facility's television system may also deliver patient teaching programs (see Fig. 4-3). A

TABLE 4-8 LEARNER CHARACTERISTICS AND TEACHING STRATEGIES BY GENERATION

Birth Year	Learner Characteristics	Recommended Teaching Strategies
Millennials		
1981-2000	• Autonomous • Multitaskers • Prefer interactive and virtual environments • Technologically focused • Integrative thinking • Short attention span	• Provide access to Internet in patient's room. • Discuss reliable websites. • Download health information to cell phones, iPods, or similar devices. • Use video games and game systems to teach health behaviors (e.g., Wii Fit).
Generation X		
1965-1980	• Interaction with groups • Self-directed learning • Self-reliant	• Use group teaching sessions. • Recommend support groups. • Suggest role playing. • Provide Internet-based education materials.
Baby Boomers		
1946-1964	• Emphasis on self-knowledge • Acquisition of knowledge from authoritative sources	• Consider lecture or lecture-discussion (e.g., PowerPoint presentation). • Use patient education TV channels. • Provide printed materials.
Veterans		
Born before 1946	• Emphasis on rote learning • Memorization of knowledge	• Consider lecture or lecture-discussion. • Use pictures and printed materials such as books.

Compiled from Rose J: Designing training for Gen Y: learning style and values of Generation Y, 2007. Retrieved from *http://trainingpd.suite101.com/article.cfm/designing_training_for_gen_y;* and Educational strategies in generational designs, *Prog Transplant* 16(1):8, 2006.

TABLE 4-9 COMPARISON OF TEACHING STRATEGIES

Description	Advantages	Limitations
Discussion ("Teach Back") • Purpose is to exchange points of view about a topic or to arrive at a decision or conclusion. • Can be done with patient, with patient and caregiver, or with group. *Example:* Weight loss	• Allows for an active exchange of information and previous experiences among participants. • Good choice when patients have previous experience with subject and have information to share. • Nonthreatening format. • Can use peers (patients with common problems) to teach.	• May require additional time depending on topic and number of participants.
Lecture-Discussion • Commonly used when group of patients and caregivers can benefit from basic information. • Lecture portion is short (i.e., 15-20 minutes). • Discussion ("teach back") follows lecture. *Example:* Basic principles of cardiac rehabilitation (e.g., exercise, nutrition)	• Combines short lecture to present basic information with time for discussion. • Provision of printed material related to lecture content is useful and recommended.	• Need to limit number of lecture topics to 5-7. • May require additional time depending on topic and number of participants.
Demonstration/Return Demonstration ("Show Back") • Purpose is to teach patient and caregiver to perform a skill. • Through return demonstration ("show back") can evaluate patient's ability to perform skill (see Fig. 4-4). *Examples:* Dressing change, injection	• Provides for learning and practice of physical skills. • Dividing skill into series of smaller steps facilitates mastery and provides reinforcement.	• May require additional time for practice needed to master skill. • Patients with limited manual dexterity may have difficulty.
Role Play • Used when patients need to • Examine attitudes and behaviors • Understand viewpoints of others • Practice carrying out ideas or decisions *Example:* Wife who rehearses how to talk with husband about need to quit smoking	• Allows participants to rehearse variety of situations involving difficult decisions, attitudes, behaviors, etc. • Practicing ahead of time may increase self-efficacy.	• May not be appropriate for all learners, since a certain level of maturity, confidence, and flexibility is required. • Requires adequate time for feedback and evaluation.
Learning Materials • Use of audiovisual materials to supplement teaching including • Printed materials (e.g., brochures) • CDs/DVDs • Hospital-based TV • Internet-based programs	• Enhance the presentation through visual and/or auditory stimulation. • Best used in combination with other teaching strategies. • Use of the Internet for health information is the preferred choice for many. • Internet access in hospitals (including patient rooms) is increasing.	• Materials must be previewed and evaluated (e.g., accuracy, completeness, reading level) before using. • Sites must be previewed and evaluated for validity of information. • Problems include limited access and inaccurate information. • May not be appropriate for all learners (e.g., lack of interest, decreased mental capacity).

FIG. 4-3 Effective teaching using a variety of strategies (written materials, video-based patient education programs).

dedicated channel may be available and contain high-quality, professionally produced programs provided on demand or on a rotating schedule. Alternatively, education programs produced by the health care facility may be available on a hospital-based channel and provide content tailored to the patient experience.

Printed educational materials are widely used for teaching patients and caregivers. These materials are most often used in combination with previously discussed teaching strategies. For instance, after a discussion on the effects of smoking on heart disease, you might use a pamphlet from the American Cancer Society to reinforce the pathophysiologic effects of smoking. For a patient who has had surgery for breast cancer, you might provide a book or magazine article written by a woman who has had a mastectomy. Suggest that the patient read this material to prepare for other teaching sessions. Recommend written materials for patients whose preferred learning style is reading.

Before using written materials with patients, evaluate the readability level if it is not indicated on the materials. Several

word processing programs (e.g., Microsoft Word) can assess the readability level of written materials. The use of Internet-based programs (e.g., *www.wordscount.info*) also can help you determine the readability and grade level of printed materials.

When writing teaching materials, use several techniques to keep the reading level at a fifth-grade level, including the following: (1) give key information first using bold or italics; (2) use short, common words of one or two syllables; (3) define medical words in simple language if they must be used; (4) keep sentences under 10 words if possible, and 15 at the most; (5) use pictures or drawings; and (6) use an active voice in the manner you would normally say something.[31] Pictographs (simple line drawings) combined with simplified text are an effective tool to improve discharge education for older adults with low literacy.[32]

Major resources for acquiring relevant printed material include the hospital or care facility library, pharmacies, public libraries, federal and state agencies, universities, voluntary organizations, research centers, and websites. Review written materials, including computer-based programs, before using them. In addition to reading level, review the material to determine whether it (1) is accurate, (2) is complete, (3) meets specific learning goals, (4) uses pictures and diagrams to stimulate interest, (5) uses one main idea or concept per pamphlet or program, (6) contains information the patient would like to know, and (7) is culture and gender sensitive and appropriate.[4]

Patients' use of the Internet to obtain health information continues to increase. Patients can quickly do an Internet search and have access to information about their disease, medications, treatments, and surgeries. Your job is to help the patient sift through the wide variety of information to find information that is valid, reliable, and usable. Understanding the principles of web searching for medical information and instructing the patient in finding valid information are critical. An estimated 80% of the people who use the Internet use it to gather health information. Factors that predict use of the Internet for this purpose include access to high-speed connections, younger age, some college education, and confidence in using technology.[33,34] Patients who are chronically ill are more likely to base health decisions on information that they find on the Internet.[33] Encourage patients to use Internet sites established by the government, universities, or reputable health-related associations (e.g., American Diabetes Association, American Heart Association, National Institutes of Health, U.S. Food and Drug Administration). Resources at the end of the chapter identify selected reliable websites for you to review and use for patient teaching.

Although older adults are using the Internet in greater numbers, many may not have the mental capacity, patience, or technical skills to successfully find information. Organizations dedicated to improving the quality of life for older adults are promoting the development of user-friendly websites (available at *www.nlm.nih.gov/pubs/checklist.pdf*) and publishing guides to help older adults evaluate web-based health information.

Obstacles to successful use of the Internet by many patients include limited access, lack of interest, and inaccurate information.[35] The presence of Internet connections in many hospital rooms provide an opportunity for you to teach patients about their illness and how to use the Internet to find health-related information.

The quantity and complexity of health care technology that patients and you have access to for patient teaching are increasing. Telehealth, interactive video, wireless technology, and podcasting are just some of the current technologies that patients may use to manage their health care. *Telehealth* is the delivery of health-related services and information via telecommunications technologies. Telehealth is used to monitor patients' cardiac rhythms, weights, and vital signs and to provide education (see Fig. 35-6). Wireless technology also may be used to monitor patients' blood glucose levels. Always educate yourself about these technologies before teaching patients.

Implementation

During the implementation phase, use the planned teaching strategies to present information and teach new skills (see Table 4-9). Incorporate verbal and nonverbal communication skills, active listening, and empathy into the process. Based on the assessment of the patient's physical, psychologic, sociocultural, and learner characteristics, determine how much the patient can participate. Whenever possible and appropriate, involve the patient's caregiver(s) in the teaching-learning process.

In implementing the teaching plan, remember the principles and characteristics of the adult learner. Reinforcement and reward are important, but be aware that phrases such as "Aren't you doing well?" in a tone one would use with a child can be condescending to adult learners.

Evaluation

Evaluation, the final step in the learning process, is a measure of the degree to which the patient has achieved the learning goals. Various evaluation techniques can be used (Table 4-10). Use techniques such as "teach back" and "show back" to determine the knowledge and skill levels of the patient and/or caregiver throughout the teaching and learning process[27,36] (Fig. 4-4). If certain goals are not reached, reassess the patient and revise the teaching plan accordingly.

For example, an older man with diabetes mellitus entered the hospital with a blood glucose level of 550 mg/dL (30.53 mmol/L). When the student nurse began to prepare his insulin injection, the nurse asked, "Are you going to have him give his own insulin and observe his technique?" "Oh, no," replied the student nurse, "He has been diabetic for 20 years!" The assumption was that a patient with diabetes would know how to perform this task

FIG. 4-4 Teaching using demonstration and return demonstration ("show back") increases successful learning by the patient.

TABLE 4-10 TECHNIQUES TO EVALUATE PATIENT AND CAREGIVER LEARNING

Technique	Strategy and Examples
Observe patient or caregiver directly.	• Ask person to show you how to change the dressing. • Return demonstration ("show back") determines whether • Skill has been mastered. • Further instruction is needed. • Patient and caregiver are ready for new or additional content.
Observe verbal and nonverbal cues.	• Teaching may need to be delayed, further teaching is needed, or different strategy should be used if patient or caregiver • Asks you to repeat instructions • Loses eye contact • Begins to doze in chair or bed • Becomes restless or fidgety • Does not speak English
Ask open-ended questions ("teach back").	• Open-ended questions provide more information about understanding than close-ended questions that require only a "yes" or "no." • Ask questions such as • "How often do you need to change the dressing?" • "What will you do if you develop chest pain after returning home?"
Talk with caregiver ("teach back").	• Involve caregiver in the evaluation process. • Ask questions such as • "What medications is she taking?" • "How often does he use his oxygen?"
Seek the patient's self-evaluation of progress.	• Ask patient's opinion about his or her progress. • What evidence does the patient have that the goals are being met? • Is the patient ready to go forward with learning new material?

correctly. The nurse and the student nurse returned to the patient's room and asked him to prepare an insulin injection ("show back"). The patient filled the syringe with 30 units of insulin and 10 units of air, instead of 40 units of insulin. After correcting the dose and questioning the patient more fully ("teach back"), the nurses concluded that the patient knew his correct dosage of insulin but could not accurately see the markings on the syringe. The patient most likely had been administering insufficient insulin to himself for some time. The patient's vision was not as good as it had been 20 years ago, and special equipment was now necessary for him to safely and accurately administer the insulin. The lesson here is that assumptions regarding a patient's knowledge and skills are dangerous. Evaluate all past and new learning as well as present abilities.

Long-term evaluation of learning goals often requires follow-up after discharge. Provide a written schedule of visits and other appropriate referrals for the patient before he or she leaves the hospital or clinic. The patient's caregiver(s) also must be familiar with the follow-up plan, so that everyone involved in the patient's long-term progress is on the same page.[18,37]

Documentation is an essential and required component throughout the entire teaching-learning process. Record everything from the assessment through plans for evaluation and follow-up. Because various members of the health care team use these records in different settings and for different reasons, the teaching goals, strategies, and evaluation results need to be clear, complete, and available to all members of the health care team.

CASE STUDY

Patient and Caregiver Teaching

Thomas M Perkins/ Shutterstock.com

Patient Profile

M.L., a 60-year-old Asian woman, is admitted to the hospital with a diagnosis of exacerbation of chronic obstructive pulmonary disease (COPD).

Subjective Data

- History of COPD for 10 years; reports a chronic cough, and denies any recent change in color of sputum; states "I stopped smoking last year but my son-in-law smokes"
- Past medical history: gastroesophageal reflux disease; macular degeneration in right eye
- Social history: widowed 5 years ago and since then has lived with daughter and son-in-law who work full time; cares for two young grandchildren after school; English is M.L.'s second language

Objective Data

Physical Examination

- Alert, cognitively intact, anxious, thin woman with dyspnea on minimal exertion; speaking in short phases or sentences; states "I have no energy"
- Using oxygen via nasal cannula at 2 L/min
- Weight 100 lb, height 5 ft 2 in
- Wears glasses

Diagnostic Studies

- Chest x-ray negative for acute infection
- Arterial blood gases on room air: pH 7.35, $PaCO_2$ 47 mm Hg, PaO_2 75 mm Hg, HCO_3^- 30 mEq/L
- O_2 saturation (via pulse oximetry) during 6-minute walk test on room air = 83%
- Forced expiratory volume in 1 second of expiration (FEV_1) = 60% of predicted

Collaborative Care

- Medications: bronchodilator therapy (inpatient nebulizer therapy, inhalers on discharge), oral corticosteroids
- Long-term home O_2 therapy: O_2 at 2 L/min via nasal cannula
- Pulmonary rehabilitation: inpatient and outpatient

Discussion Questions

1. ***Priority Decision:*** Given M.L.'s history, what are the priority learning needs?
2. What factors (e.g., sociocultural, physical, psychologic) may influence M.L.'s response to teaching?
3. What potential challenges might you expect when planning to teach M.L.? How would you manage them?
4. ***Priority Decision:*** Identify two priority nursing diagnoses. Develop a teaching plan for M.L. based on these nursing diagnoses.

evolve Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. What would be the priority teaching goal for a middle-aged Hispanic woman regarding methods to relieve symptoms of menopause?
   a. Prevent the development of future disease.
   b. Maintain the patient's current state of health.
   c. Change the patient's cultural belief regarding the use of herbs.
   d. Provide information for selection and use of treatment options.
2. When planning teaching with consideration of the diverse learning needs of adults, the nurse's best approach would include
   a. presenting material in an efficient lecture format.
   b. recognizing that adults enjoy learning regardless of the relevance to their personal lives.
   c. providing opportunities for the patient to learn from other adults with similar experiences.
   d. postponing practice of new skills until the patient can independently practice the skill at home.
3. Which is the priority patient teaching strategy when limited time is available?
   a. Setting realistic goals that have high priority for the patient
   b. Referring the patient to a nurse educator in private practice for teaching
   c. Observing more experienced nurse-teachers to learn how to teach faster and more efficiently
   d. Providing reading materials for the patient instead of discussing information the patient needs to learn
4. The nurse needs to include caregivers in patient teaching primarily because *(select all that apply)*
   a. they provide most of the care for patients after discharge.
   b. they might feel rejected if they are not included in the teaching.
   c. patients have better outcomes when their caregivers are involved.
   d. the patient may be too ill or too stressed to fully understand the teaching.
   e. caregivers are responsible for the overall management of the patient's care.
5. Which technique is most appropriate when using motivational interviewing with a patient who tells you that he is ready to start a weight loss program?
   a. Confirm that the patient is serious about losing weight.
   b. Insist that the patient consider an organized group weight loss program.
   c. Focus on the patient's strengths to support his optimism that he can successfully lose weight.
   d. Ask a prescribed set of questions to increase the patient's awareness of his dietary behaviors.
6. Which patient characteristic enhances the teaching-learning process?
   a. Moderate anxiety
   b. High self-efficacy
   c. Being in the precontemplative stage of change
   d. Being able to laugh about the current health problem
7. A patient tells the nurse that she enjoys talking with others and sharing experiences, but easily falls asleep when reading. Which teaching strategy would be most effective with this patient?
   a. Role play
   b. Group teaching
   c. Lecture-discussion
   d. Discussion supplemented with computer programs
8. The nurse has taught a patient's caregiver how to administer insulin to her husband. Evaluation of the nurse's teaching effectiveness before discharge would include
   a. arranging for follow-up with a home care nurse.
   b. monitoring the patient's glucose readings before discharge.
   c. asking the caregiver to "show back" her ability to administer insulin.
   d. asking the caregiver what she found helpful about the teaching experience.

1. d, 2. c, 3. a, 4. c, d, 5. c, 6. b, 7. b, 8. c.

LEARNING OUTCOMES

1. Describe the prevention and major causes of chronic illness.
2. Explain the characteristics of a chronic illness.
3. Define *ageism*.
4. Explain the needs of special populations of older adults.
5. Describe nursing interventions to assist older adults with chronic conditions.
6. Describe common problems of older adults related to hospitalization and acute illness and the nurse's role in assisting them.
7. Differentiate among care alternatives to meet needs of older adults.
8. Describe the nurse's role in health promotion, disease prevention, and managing the special needs of older adults.

KEY TERMS

ageism, p. 65
chronic illness, Table 5-1, p. 61
elder mistreatment, p. 68
ethnogeriatric, p. 67
frail older adult, p. 64
gerontologic nursing, p. 71
Medicaid, p. 69
Medicare, p. 68
old-old adult, p. 64
young-old adult, p. 64

This chapter discusses issues related to chronic illness and aging. The population of older adults is growing quickly and they often have increased health care needs and problems that you need to consider.

CHRONIC ILLNESS

Illness can be categorized as either acute or chronic (Table 5-1). Today the U.S. health care system faces a growing burden of chronic illness as the population ages. Chronic diseases account for 70% of all deaths in the United States.[1] Chronic illness results in limitations in physical functioning, work productivity, and quality of life for nearly 1 out of 10 Americans, or about 31 million people. Older adults often live with more than one chronic illness. A significant portion of U.S. health care dollars go toward the treatment of chronic illnesses.[1] The management of a chronic illness can profoundly affect the lives and identities of the patient, family, and caregiver. Table 5-2 presents the impact of some chronic illnesses.

TABLE 5-1 CHARACTERISTICS OF ACUTE AND CHRONIC ILLNESS

Description	Characteristics
Acute Illness	
Diseases that have a rapid onset and short duration *Examples:* colds, influenza, acute gastroenteritis	• Usually self-limiting • Responds readily to treatment • Complications infrequent • After illness, return to previous level of functioning
Chronic Illness	
Diseases that are prolonged, do not resolve spontaneously, and are rarely cured completely *Examples:* see Table 5-2	• Permanent impairments or deviations from normal • Irreversible pathologic changes • Residual disability • Special rehabilitation required • Need for long-term medical and/or nursing management

Cox, RN, MS, Professor, Nursing, Sinclair Community College, Dayton, Ohio.

TABLE 5-2 IMPACT OF CHRONIC ILLNESSES

Chronic Illness	Impact	Content in Book: Chapter	Content in Book: Page
Alzheimer's disease	• Affects 5.4 million people • 6th leading cause of death	60	1445
Arthritis	• Affects 1 in 5 people • One of most common chronic illnesses	65	1562
Cancer	• 2nd leading cause of death	16	247
Chronic obstructive pulmonary disease	• Affects many older adults • 3rd leading cause of death	29	579
Coronary artery disease	• Affects about 17 million adults • Leading cause of death	34	731
Diabetes	• Affects >25.8 million Americans • 7.0 million do not know they have the disease • 7th leading cause of death	49	1153
Heart failure	• Most common reason older adults are hospitalized	35	766
Obesity	• Affects >35% of adults • Major contributor to other health problems	41	906
Stroke	• Affects about 7 million adults, 15%-30% disabled • 4th leading cause of death	58	1388

TABLE 5-3 CHRONIC ILLNESS TRAJECTORY

Phases	Description
Onset	• Signs and symptoms are present. • Disease diagnosed.
Stable	• Illness course and symptoms controlled by treatment regimen. • Person maintains everyday activities.
Acute	• Active illness with severe and unrelieved symptoms or complications. • Hospitalization may be required for management.
Comeback	• Gradual return to an acceptable way of life.
Crisis	• Life-threatening situation occurs. • Emergency services are necessary.
Unstable	• Unable to keep symptoms or disease course under control. • Life becomes disrupted while patient works to regain stability. • Hospitalization not required.
Downward	• Gradual and progressive deterioration in physical or mental status. • Accompanied by increasing disability and symptoms. • Continuous alterations in everyday life activities.
Dying	• Patient has to relinquish everyday life interests and activities, let go, and die peacefully. • Immediate weeks, days, hours preceding death.

Source: Woog P: *The chronic illness trajectory framework: the Corbin and Strauss nursing model,* New York, 1992, Springer.

In addition to people living longer, other societal changes have contributed to the increase in chronic illnesses, including insufficient physical activity, lack of access to fresh fruits and vegetables, tobacco use, and alcohol consumption.[1]

Trajectory of Chronic Illness

Chronic illnesses may have acute exacerbations in which an individual moves from a level of optimum functioning, with the illness well controlled, to a period of instability during which the individual may need assistance. Corbin and Strauss proposed a view of chronic illness as a trajectory (Fig. 5-1) with overlapping phases[2] (Table 5-3). This trajectory characterizes the common course of most chronic illnesses. In addition,

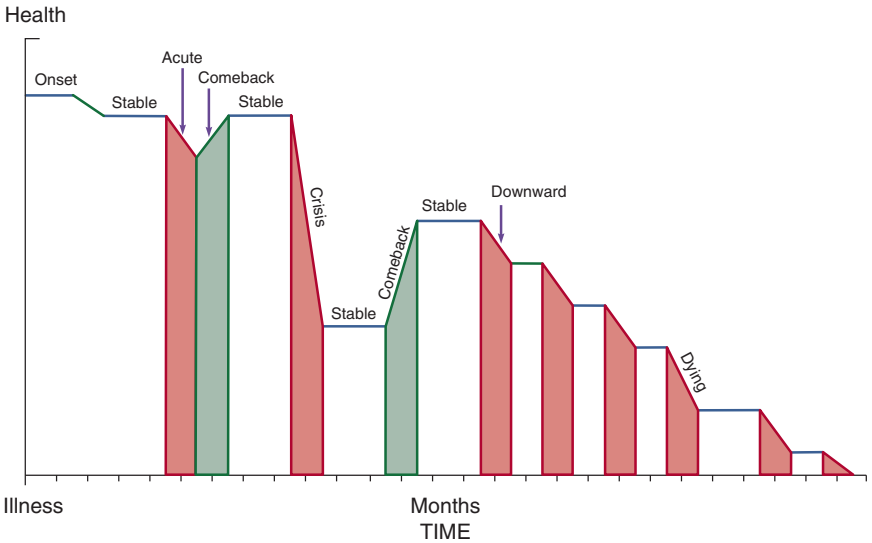

FIG. 5-1 The Chronic Illness Trajectory is a theoretical model of chronic illness. The trajectory model of chronic illness recognizes that chronic illness will have many phases (see Table 5-3).

TABLE 5-4 SEVEN TASKS OF PEOPLE WITH CHRONIC ILLNESS

1. Prevent and manage a crisis.
2. Carry out prescribed treatment regimen.
3. Control symptoms.
4. Reorder time.
5. Adjust to changes in course of disease.
6. Prevent social isolation.
7. Attempt to normalize interactions with others.

Source: Corbin JM, Strauss A: A nursing model for chronic illness management based upon the trajectory framework, *Sch Inq Nurs Pract* 5:155, 1991.

TABLE 5-5 CHARACTERISTICS OF TREATMENT REGIMENS

Characteristic	Example
Difficult	Managing a home hemodialysis unit
Time consuming	Dressing changes done four times daily
Painful or uncomfortable	Injecting heparin daily in the abdomen
Unsightly appearance	Tracheostomy
Slow rate of effectiveness	Lowering blood cholesterol level with medication or diet

Corbin and Strauss identified the seven tasks of those who are chronically ill[2] (Table 5-4). These tasks are discussed in the following sections.

Preventing and Managing a Crisis. Most chronic illnesses have the potential for an acute exacerbation of symptoms, which may result in further disability or death. Examples include the patient with heart disease who has another myocardial infarction or the patient with asthma who has a severe attack. A major task for both the patient and the caregiver is to learn to prevent or manage the crisis. First, the patient and caregiver need to understand the potential for the crisis to occur. Second, they need to know ways to prevent or modify the threat. This often involves adherence to a prescribed medical regimen. Patients also need to know the signs and symptoms of the onset of a crisis. Depending on the chronic illness, signs and symptoms may occur suddenly (e.g., seizure in a patient with seizure disorder) or slowly (e.g., heart failure in a patient with untreated hypertension). It is important for the patient and caregiver to develop a plan to manage a crisis that is likely to occur.

Carrying Out Prescribed Treatment Regimens. Treatment regimens vary in degree of difficulty and the impact that they have on the person's lifestyle. Characteristics of treatment regimens are included in Table 5-5.

Controlling Symptoms. An important task for those with chronic illnesses is to learn to control symptoms so that desired activities may be continued. Some individuals redesign their lifestyle by learning to plan ahead, such as the person with irritable bowel syndrome choosing to go only to events where there are restrooms near the seating area. Others may redesign their living space. Patients and their families or caregivers need to learn about the pattern of symptoms, such as typical onset, duration, and severity, so that lifestyle can be changed accordingly.

Reordering Time. Patients with chronic illness often report having too much or too little time. Treatment plans that require large amounts of time for the patient, as well as caregivers, may necessitate changing schedules or eliminating other activities.

Adjusting to Changes in Course of Disease. Some diseases, such as multiple sclerosis, have unpredictable courses that make planning activities difficult. Part of the patient's task is to develop a personal identity that includes the chronic illness and adjust to the lifestyle changes it necessitates.

Preventing Social Isolation. Social isolation may occur with chronic illness because the individual chooses to withdraw from previous activities or because others withdraw from the chronically ill person. An example is a man who has aphasia secondary to a stroke who may be unwilling to go out in public because he is embarrassed because of communication problems.

Attempting to Normalize Interactions With Others. Most individuals with chronic illness attempt to manage symptoms so that they can hide their disabilities or disfigurement. This may involve wearing a prosthesis or demonstrating that they can function the same as a person without a disability or chronic illness. An example of this is the man with chronic lung problems who stops walking to catch his breath, but appears to be inspecting a plant or looking in a store window.

Prevention of Chronic Illness

Chronic illnesses are often preventable. *Primary prevention* refers to measures such as proper diet, proper exercise, and immunizations that prevent the occurrence of a specific disease. *Secondary prevention* refers to actions aimed at early detection of disease that can lead to interventions to prevent disease progression. *Tertiary prevention* refers to activities that limit disease progression, such as rehabilitation.[3]

NURSING MANAGEMENT CHRONIC ILLNESS

Diagnosis and treatment of the acute phase or acute exacerbations of a chronic illness are sometimes done in a hospital. Other phases of a chronic illness are managed in an ambulatory care setting, at home, in an assisted living facility, or in a skilled nursing facility. The course of chronic illness is often unpredictable. The management of a chronic illness can profoundly affect the lives of the patient, caregiver, and family.

An assessment of health status includes an individual's level of daily functioning and his or her perception of relative health or illness. This health assessment includes activities of daily living (ADLs), such as bathing, dressing, eating, toileting, and transfer. It also includes instrumental ADLs (IADLs), such as using a phone, shopping, preparing food, housekeeping, doing laundry, arranging transportation, taking medications, and handling finances.

Because the majority of chronic illnesses are treated in an ambulatory care setting, it is increasingly important for patients and caregivers to understand and manage their own health. The term *self-management* refers to the individual's ability to manage his or her symptoms, treatment, physical and psychosocial consequences, and lifestyle changes in response to living with a long-term disorder.[4]

You play an important role in the management of individuals with chronic illness. This begins with planning care, teaching the patient and caregiver regarding the treatment plan, implementing strategies for symptom management, and assessing patient outcomes.

Family caregivers (e.g., spouses, adult children, partners) often have important roles in the life of the chronically ill person. The ideal situation is one in which family caregivers

work together with the patient to manage the illness. This collaboration begins under the direction of the health care team at the time of diagnosis. When the caregiver is a spouse who is also older, he or she may have a chronic illness as well, which complicates the situation.[5] The stresses and needs of family caregivers are discussed in Chapter 4 and Table 4-5.

OLDER ADULTS

DEMOGRAPHICS OF AGING

In the past three decades the older adult population (those 65 years of age and older) has grown twice as fast as the rest of the population. Almost 40 million people, or 13% of the population, are age 65 or older.[6] Nearly one in five U.S. residents is expected to be 65 or older by 2030. The number of Americans age 85 or older is expected to more than triple, from 5.8 million to 19 million, between 2010 and 2050.[6] This dramatic increase is in part due to aging of the *Baby Boomers* (those born between 1946 and 1964) who began to turn 65 in 2011.

Upcoming cohorts of older adults will be better educated than previous cohorts and have greater access to technology and resources. In the United States 13% of people over age 65 are people of color, including 8% African Americans; 3% Asian/Pacific Islanders; and less than 1% American Indians, Eskimos, and Aleuts. People of Hispanic/Latino ethnicity (who may be of any race) represent 7% of the older population.[1] By 2030 the proportion of older adults who are people of color will increase 160% (Latinos 202%; African Americans 114%; American Indians, Eskimos, and Aleuts 145%; and Asian/Pacific Islanders 145%), while growth in the European-American population will increase by only 59%.[6]

Other factors add to the overall increase in the older population. Common diseases of the early to mid-twentieth century that killed many people before they reached older age, such as influenza and diarrhea, are now less common. Declining infant mortality, new drug therapies, mechanical devices, improved surgical interventions, health promotion, and earlier detection and treatment of diseases have contributed to the increase in life span.

The U.S. Census Bureau predicts life expectancy to continue to increase for both men and women. Men and women born in 1950 who reach age 65 can expect, on average, another 12.8 and 15.8 years of life, respectively.[1,7] Whether this gender difference is due to differences in health behaviors (e.g., smoking, alcohol use) or occupation is not known.[8]

The fastest-growing segment of older Americans is people ages 85 or older. Since the 1960s, this group has increased 250%. The terms **young-old adult** (65 to 74 years of age) and **old-old adult** (85 years of age and older) describe two groups of older adults with different characteristics and needs. The old-old adult is often a woman who is widowed, divorced, or single and dependent on family for support. Many have outlived children, spouses or partners, and siblings. Old-old adults are often characterized as hardy, elite survivors. Because old-old adults have lived so long, they may have become the family icon, the symbol of family tradition and legacy.

Nearly 6% of individuals age 65 to 74 and 25% of those 85 and older live in nursing homes.[8] The **frail older adult** is usually over age 75 and has physical, cognitive, or mental dysfunctions that may interfere with independently performing ADLs.[9] (Older frail adults are discussed later in this chapter.)

EVIDENCE-BASED PRACTICE

Translating Research Into Practice

What Is the Effectiveness of Chronic Illness Strategies for Asian/Pacific Islanders?

Clinical Question

What is the effectiveness (O) of self-management interventions (I) on chronic illness in Asian/Pacific Islanders (P)?

Best Available Evidence

Systematic review of randomized controlled trials (RCTs)

Critical Appraisal and Synthesis of Evidence

- 21 RCTs (n = 4446) related to chronic illness self-management and self-care in male and female Asian/Pacific Islanders, including Asians from Far East, Southeast Asia, or Indian subcontinent, and Pacific Islanders from Hawaii, Guam, and Samoa.
- Many chronic health conditions were examined, with diabetes mellitus being the most common.
- Alternative therapies (exercise and body-mind-spirit), cognitive-behavioral interventions (CBI), and health education programs lasting from 1 month to 2 years were included.
- All interventions, especially CBI, resulted in positive and significant health outcomes, including improvements in mood and quality of life.

Conclusion

- Self-management interventions assist Asian/Pacific Islanders in restoring and maintaining health while preventing disease.

Implications for Nursing Practice

- Tailor self-management interventions for ethnically diverse groups and monitor outcomes.
- Teach and assist patients in caring for themselves.
- Support patient self-management strategies that promote health.

Reference for Evidence

P, Patient population of interest; *I*, intervention or area of interest; *O*, outcomes of interest (see p. 12).

ATTITUDES TOWARD AGING

Who is old? The answer to this question often depends on the respondent's age and attitude. It is important to understand that aging is normal and is not related to pathology or disease. Age is established by a date in time and is influenced by many factors, including emotional and physical health, developmental stage, socioeconomic status, culture, and ethnicity.[10]

As people age, they are exposed to new and different life experiences. The accumulation of these differences makes older adults more diverse than any other age-group. As you assess older adults, consider and value their diversity and life history. Also assess their own perceptions of what it means to be an older adult. Older adults with poor health report a higher perceived age and lower sense of well-being when compared with healthy older adults. The majority of older adults report having good-to-excellent health despite having a chronic illness. Age is important, but it may not be the most relevant factor in determining appropriate care of an individual older adult patient.

Myths and stereotypes about aging are often supported by media reports of older adults who are "problematic." These commonly held misconceptions may lead to errors in assessment and unnecessary limitations or interventions. For example, if you think that all older people are rigid in their thinking, you

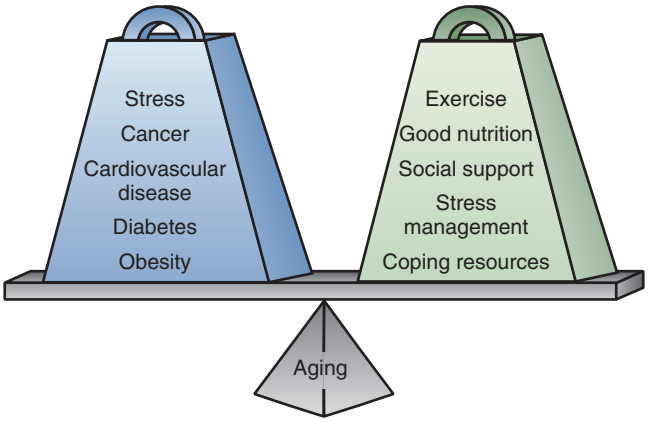

FIG. 5-2 The aging process can be viewed as a balance between negative and positive factors.

may not present new ideas to a patient.[11] **Ageism** is a negative attitude based on age. Ageism leads to discrimination and disparities in the care given to older adults. If you demonstrate negative attitudes, it may be because you fear your own aging process or you are not knowledgeable about aging and the health care needs of the older adult. Therefore it is important to gain knowledge about normal aging and have increased contact with older adults who are healthy and live independently. Also, it is your role as a nurse to dispel myths of aging.

BIOLOGIC AGING

From a biologic view, *aging* is defined as the progressive loss of function. The exact cause of biologic aging is unknown. Biologic aging is a multifactorial process involving genetics, diet, and environment.[12] In part, biologic aging can be viewed as a balance of positive and negative factors (Fig. 5-2).

Research is directed at increasing both the average life span and the quality of life of older adults. The hope is that new antiaging therapies will be developed to slow down or reverse age-related changes that result in chronic illness and disability. Based on numerous laboratory studies in rodents, caloric restriction (reducing dietary intake by 25% to 50%) has been consistently shown to significantly extend the life span.[13] It may be that caloric restriction results in changes in body composition, metabolism, and hormones that are conducive to long life. Caloric restriction in humans is associated with decreases in the incidence of obesity, diabetes, hypertension, and cancer, all of which are associated with aging.[13,14]

A number of nutrients have been tested for their potential benefits in reducing the impact of aging. Examples include β-carotene, selenium, vitamin C, and vitamin E. To date, research has failed to show that large doses of these supplements prevent chronic illness, such as heart disease or diabetes.[15] However, much more research is needed before it is determined whether any of these substances will delay aging or enhance the functional ability of older adults.

AGE-RELATED PHYSIOLOGIC CHANGES

Age-related changes affect every body system. These changes are normal and occur as people age. However, the age at which specific changes occur differs from person to person and within the same person. For instance, a person may have gray hair at age 45 but relatively unwrinkled skin at age 80. In your role as a nurse, assess for age-related changes. Table 5-6 presents a list of tables where specific age-related assessment findings can be found throughout the book.

TABLE 5-6 GERONTOLOGIC ASSESSMENT DIFFERENCES

Summary of Tables

Body System	Table Number	Page
Visual	21-1	371
Auditory	21-7	380
Integumentary	23-1	417
Respiratory	26-4	481
Hematologic	30-3	619
Cardiovascular	32-1	691
Gastrointestinal	39-5	871
Urinary	45-2	1051
Endocrine	48-3	1141
Reproductive	51-3	1225
Nervous	56-4	1344
Musculoskeletal	62-1	1494

SPECIAL OLDER ADULT POPULATIONS

Chronically Ill Older Adults

Daily living with chronic illness is a reality for many older adults. The incidence of chronic illness triples after age 45. Most people 65 years of age and older have at least one chronic condition, and many have multiple conditions.[1] The most common chronic conditions in older adults are hypertension, osteoarthritis, heart disease, cancer, and diabetes. Other common chronic conditions include Alzheimer's disease, vision and hearing deficits, osteoporosis, hip fractures, stroke, Parkinson's disease, and depression.

Older Adult Women

For the aging woman, the impact of an aging body and being a woman is considered double jeopardy. Many factors have a significant negative impact on the health of older women (see Gender Differences box). Many of these factors are directly

GENDER DIFFERENCES

Older Adults

Men
- More likely to be living with spouse
- More likely to have health insurance
- Higher income after retirement
- Less likely to be involved in caregiving activities
- Generally have fewer chronic health problems than women

Women
- More likely to live alone
- Loss of spouse more common
- Less likely to have health insurance
- More likely to live in poverty
- Poverty rates highest among minority women
- Lack of formal work experience leading to lower income
- More likely to rely on Social Security as major source of income
- More likely to be caregiver of ill spouse
- Have a higher incidence of chronic health problems such as arthritis, hypertension, stroke, and diabetes

TABLE 5-7 GERONTOLOGIC ASSESSMENT DIFFERENCES

Cognitive Function

Cognitive Function	Effect of Aging
Fluid intelligence	Declines during middle age
Crystallized intelligence	Improves
Vocabulary and verbal reasoning	Improves
Spatial perception	Constant visuospatial perception Declines in spatial navigation tasks
Synthesis of new information	Declines during middle age
Mental performance speed	Declines during middle age
Short-term recall memory	Declines during old age
Long-term recall memory	Constant

related to reduced financial resources and the greater longevity of women compared with men. Thus older women often experience disparities, including unequal access to quality health care. (Health disparities are discussed in Chapter 2.) As a nurse, you are in an excellent position to be an advocate for equity for older women in the health care system. Advocacy organizations, such as the Older Women's League (OWL) and the Society for Women's Health Research, can be helpful in this process.

Cognitively Impaired Older Adults

Most healthy older adults have no noticeable decline in cognitive abilities (Table 5-7). Older adults may experience memory lapses or benign forgetfulness, which is significantly different from cognitive impairment. This is also referred to as *age-associated memory impairment*. Encourage older adults with memory loss to be evaluated by their primary care provider, and to use memory aids, attempt recall in a calm and quiet environment, and actively engage in memory improvement techniques. Memory aids include clocks, calendars, notes, marked pillboxes, safety alarms on stoves, and identity necklaces or bracelets. Memory techniques include word association, mental imaging, and mnemonics.

Declining physical health is an important factor that influences cognitive impairment. Older adults who experience sensory loss, heart failure, or cerebrovascular disease may show a decline in cognitive functioning.[16] Cognitive impairment, delirium, and dementia are discussed in Chapter 60.

Rural Older Adults

People over age 65 are less likely to live in metropolitan areas than younger people. Five barriers to health care access for older adults are transportation, limited supply of health care workers and facilities, lack of quality health care, social isolation, and financial limitations.[17,18] Rural older adults are often stressed by declining self-care abilities. Particularly vulnerable are older adults of color living in rural areas, who have even less access to health care providers. In addition, older adults who live in rural areas may be less likely to engage in health-promoting activities.

When you work with older adults in rural areas, recognize lifestyle values and practices of rural life (Fig. 5-3). In planning care, be aware that transportation is the number one barrier to health care for rural older adults. Alternative service approaches such as computer-based Internet sources and chat rooms, DVDs, radio, community centers, and church social events can be used to promote healthful practices or to conduct health screening (Fig. 5-4). The development of telehealth devices for

FIG. 5-3 Older adults living in rural areas often enjoy outside activities, such as gardening. (iStockphoto/Thinkstock)

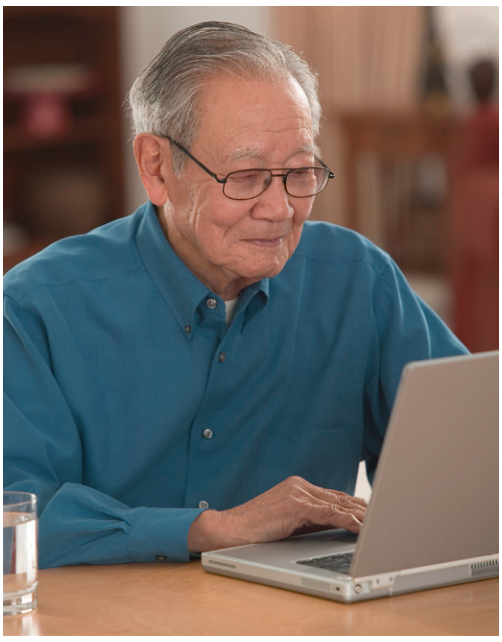

FIG. 5-4 Older adults are using computers more frequently and accessing health care information on the Internet. (Comstock Images/Thinkstock)

INFORMATICS IN PRACTICE

Older Adults and Internet Use

- Forty percent of older adults use the Internet to look for health information.
- Older adults are more likely to accept as true what they read on a Web page. This is related to a lack of Internet experience and confusion from the large amounts of available information.
- Teach patients who use the Internet as a source of information how to assess the credibility of a website.
- Suggest the use of websites that include senior-friendly design elements.

monitoring patients in their home environments has enhanced the ability to provide care to isolated individuals.[19] Innovative models of nursing practice must continue to be developed to assist the rural older adult.[20]

Homeless Older Adults

The number of older adults who are homeless is increasing. Key factors associated with homelessness include (1) having a low income, (2) having reduced cognitive capacity, (3) living alone, and (4) living in a community that lacks affordable housing. Homeless older adults may be chronically homeless or recently homeless because of a crisis in either health or economic status.[21]

Mortality rates for homeless older adults are three times higher than for older adults who have housing. Older adults who are homeless have more health problems and appear older. They are also at additional risk because many aging network services are not designed to reach out to people who are homeless. Older people who are homeless are less likely to use shelters or meal site services than younger homeless people.[22] Long-term care placement is often an alternative to homelessness, especially when the person is cognitively impaired and alone. Fear of institutionalization may explain why homeless older adults do not use shelter and meal site services. Care for homeless older adults requires an interdisciplinary approach (including nurses, physicians, social workers, clerical workers, and transporters) that links shelters with outreach, primary care clinics, Medicare and Medicaid offices, and pharmacies.

Frail Older Adults

Frailty is a geriatric syndrome in which three or more of the following are present: advanced age, unplanned weight loss (10 lb or more in the past year), weakness, poor endurance and energy, slowness, and low activity levels. Risk factors include disability, multiple chronic illnesses, and dementia. People are more likely to become frail if they smoke, have a history of depression or long-term medical health problems, or are underweight. The old-old population (85 years of age or older) is most at risk for frailty, although many in this age-group remain healthy and robust.

Older frail adults have difficulty coping with declining functional abilities and decreasing daily energy. When stressful life events (e.g., death of a pet) and daily strain (e.g., caring for an ill spouse) occur, frail older adults often cannot cope with the effects of stress and, as a result, may become ill. Common health problems of frail older adults include mobility limitations, sensory impairment, cognitive decline, falls, and increasing frailty.[23]

Frail older adults tire easily; have little physical reserve; and are at risk for disability, elder mistreatment, and institutionalization. Frail older adults are especially at risk for malnutrition and dehydration, which are related to factors such as living alone, depression, and low income. Other factors, such as declining cognitive status, inadequate dental care, sensory decreases, physical fatigue, and limited mobility, increase the risks of malnutrition and dehydration. Monitor frail older adults for adequate calorie, protein, iron, calcium, vitamin D, and fluid intake. Because medications may interfere with nutrition, perform a thorough medication review, including prescription drugs, over-the-counter drugs, vitamins, minerals, supplements, herbal remedies, and cultural remedies.

TABLE 5-8 SCALES: NUTRITIONAL ASSESSMENT OF OLDER ADULTS

The acronym SCALES can remind you to assess important nutritional indicators:

Sadness, or mood change
Cholesterol, high
Albumin, low
Loss or gain of weight
Eating problems (e.g., mechanical problems such as impaired swallowing, poor dentition)
Shopping and food preparation problems

A tool to assess the risk factors for poor nutritional status in older adults is presented in Table 5-8. Once an older adult's nutritional needs are identified, common interventions include home-delivered meals, dietary supplements, food stamps, dental referrals, and vitamin supplements.

CULTURALLY COMPETENT CARE

OLDER ADULTS

The term **ethnogeriatric** describes the specialty area of providing culturally competent care to older adults.[24] As American society changes, ethnic institutions and neighborhoods may also change. For the older adult with strong ethnic and cultural roots, there may be a loss of friends who speak the "mother tongue," a loss of the religious institution that supports social ethnic activities, and a loss of stores that carry desired ethnic foods. This sense of loss is increased when children and others deny or ignore ethnic and cultural practices. Support for older adults of color is most frequently found in the family, religious practices, and isolated geographic or community ethnic clusters. In the old-old population, members of an ethnically diverse group often live with extended family and continue to speak their native language.

Ethnic populations of older adults face unique problems. Because older adults often live in older neighborhoods, physical security and personal safety related to crime may be a concern. Individuals with ethnic identities often have disproportionately lower incomes and may not be able to afford Medicare deductibles or drugs needed to treat chronic illnesses.[25] Perceptions of health may also differ by ethnic group. Among older adults, fewer African Americans and Hispanic/Latinos rate their health as excellent or good as compared with white older adults.[26]

Assess each older adult's ethnic and cultural orientation. Do not assume that ethnicity and culture are or are not of value to the patient and the patient's family until you do an assessment. For you to be effective with the ethnic older adult, a sense of respect and clear communication are critical. Nursing interventions to assist in meeting the needs of ethnic populations are described in Table 2-9. (Culturally competent care is discussed in Chapter 2.)

SOCIAL SUPPORT FOR OLDER ADULTS

Social support for older adults occurs at three levels. First, family members are the primary and preferred providers of social support. Second, a semiformal level of support is found in clubs, religious (or faith-based) organizations, neighborhoods, and senior citizen centers. Third, older adults may be

linked to formal systems of social welfare agencies, health facilities, and government support. Generally, you, as a nurse, are part of the formal support system.

Family Caregivers

Many older adults require caregiving by family members. Other older adults may take on the role of caregiver for someone in their family, usually their spouse or partner. Many family caregivers caring for older adults are themselves age 65 or over.[27] The challenges of caregiving are discussed in Chapter 4 on pp. 51 to 52.

Elder Mistreatment or Abuse

Elder mistreatment (EM) describes intentional acts of omission or commission by a caregiver or "trusted other" that cause harm or serious risk of harm to a vulnerable older adult. EM may occur in community (home or assisted living facility) or long-term care (institutional) settings.

Approximately 2% to 10% of community-dwelling older adults in the United States are abused, neglected, or exploited by trusted others.[28] The prevalence of EM in institutional settings is unknown, but it is thought to be widespread. Although EM rates are similar in women and men, the majority of victims are women because of the predominance of women in older age cohorts. Victims of EM have a mortality risk that is three times higher than that of nonmistreated peers. The higher mortality risk is not due to the abuse or neglect itself, but rather may be due to stress-related illnesses associated with prolonged mistreatment.[29]

EM is a hidden problem. For every reported case in the community setting, more than five cases go unreported. Underreporting may be higher based on immigration status, ethnic background, or sexual orientation. Victims are unlikely to report mistreatment by "trusted others" because of isolation; impaired cognitive or physical function; feelings of shame, guilt, or self-blame; fear of reprisal; pressure from family members; fear of nursing home placement; or cultural norms. Health care providers also underreport, possibly because of failure to suspect or recognize EM, perceived inability to successfully intervene, desire to avoid responsibility for further action, or ageism.

Much of domestic EM is family violence that involves power and control dynamics. Family members are responsible for up to 90% of domestic EM. Adult children who abuse, neglect, or exploit their parents are usually dependent on their parent(s) for housing and financial support, have a history of violence, are unemployed, and/or are disabled from substance abuse or mental illness. Abusive spouses or partners may either initiate intimate partner violence in older age or continue a lifelong pattern of abuse.[30]

Many factors put community-dwelling older adults at risk for domestic EM. These include (1) physical or cognitive dysfunction that leads to an inability to perform ADLs (and therefore produces dependence on others for care), (2) any psychiatric diagnoses (especially dementia and depression), (3) alcohol abuse, and (4) decreased social support.[31] In long-term care settings the same factors that lead to institutionalization are risk factors for mistreatment by staff, visitors, and others. These include dependence on others for care because of physical or cognitive dysfunction (especially conditions that produce aggressive behaviors). Residents of long-term care facilities are also at risk for harmful aggression by other residents.[32]

Types of EM, characteristics, and manifestations are shown in Table 5-9. EM types frequently co-occur, and up to 70% of cases involve neglect. In institutional settings EM includes the types described in Table 5-9, but also includes failure to follow the plan of care, unauthorized use of physical or chemical restraints, overuse or underuse of medication, or isolation as punishment.

Assess for and consider EM if you observe any of these characteristics or manifestations. Perform a thorough history and physical examination that includes screening for mistreatment. Follow your organization's protocols for EM screening and interventions. Tools that are helpful in assessment include the Elder Mistreatment Assessment and the American Medical Association's Diagnostic and Treatment Guidelines on Elder Abuse and Neglect (see Resources at the end of this chapter).

It is important that you interview patients alone because, if mistreatment is occurring, they may not disclose in the presence of the person who accompanied them, especially if that person is the abuser. Be especially attentive to explanations about injuries that are not consistent with what you observe, contradictory explanations between the patient and the caregiver, or behavioral clues that suggest the patient is being threatened or intimidated. Additional nursing interventions are listed in Table 5-10. In most states, health care workers and others are mandated to report suspected or actual EM to Adult Protective Services and/or law enforcement. Know your legal responsibilities by checking the laws in your state.

Self-Neglect

Despite the prevalence of mistreatment of older adults by trusted others, the majority of referrals made to Adult Protective Services are for self-neglect. Older adults who self-neglect are likely to live alone; refuse or are unable to meet their basic needs; have multiple, untreated medical or psychiatric conditions; and live in squalor. Like EM, older community-dwelling adults who self-neglect face a higher risk of mortality than peers who do not self-neglect. Nursing interventions include assessment for possible self-neglect, referrals for long-term multidisciplinary case management, and referral to Adult Protective Services.[33]

SOCIAL SERVICES FOR OLDER ADULTS

A network of services supports older adults both in the community and in health care facilities. In the United States most older adults are the beneficiaries of at least one social or governmental service. To understand the older adult's situation, learn about government structures that fund and regulate programs for older adults. The Administration on Aging (AoA), which is part of the Department of Health and Human Services, is the federal agency responsible for many older adult programs. Funding from the AoA is funneled to state and local Area Agencies on Aging.[34]

MEDICARE AND MEDICAID

Medicare is a federally funded health insurance program for people ages 65 years or older, as well as for people under age 65 with certain disabilities and people of any age with end-stage kidney disease requiring dialysis or a kidney transplant. Nursing documentation is critically important for adequate reimbursement of services.

TABLE 5-9 TYPES OF ELDER MISTREATMENT

Characteristics	Manifestations
Physical Abuse	
Slapping, striking; restraining; incorrect positioning; oversedation with medications	Bruises, bilateral injuries (ankles, wrists), repeated injuries in various stages of healing; oversedation; use of several emergency departments
Neglect	
Failure or refusal to provide basic life needs, including food, water, medications, clothing, hygiene; failure to provide physical aids such as dentures, eyeglasses, hearing aid; failure to ensure safety	Older adult's reports of being neglected; untreated or infected pressure ulcers on sacral area, heels; loss of body weight; laboratory values showing dehydration (e.g., ↑ Hct, ↑ serum sodium), malnutrition (↓ serum protein); poor personal hygiene; lack of adherence with medical treatment
Failure to provide social stimulation; leaving alone for long periods; failure to provide companionship	Depression, withdrawn behavior; agitation; ambivalent attitude toward caregiver or family member
Psychologic Abuse	
Berating verbally; harassment; intimidation; threats of punishment or deprivation; childlike treatment; isolation	Depression, withdrawn behavior; agitation; ambivalent attitude toward caregiver or family member
Sexual Abuse	
Nonconsensual sexual contact, including touching inappropriately; forced sexual contact	Older adult's report of sexual abuse; unexplained vaginal or anal bleeding; bruised breasts; unexplained STIs or genital infections
Financial Abuse	
Denying access to personal resources, stealing money or possessions; coercing to sign contracts or durable power of attorney; making changes in will or trust	Living situation below level of personal resources; sudden change in personal finances; sudden transfer of assets
Violation of Personal Rights	
Denying right to privacy or right to make decisions regarding health care or living environment; forcible eviction	Sudden inexplicable changes in living situation; confusion
Abandonment	
Desertion of an older person by an individual who has assumed responsibility for providing care or by a person with physical custody	Older adult's reports of being abandoned; desertion of an older adult at a hospital or nursing facility, shopping center, or other public place

Hct, Hematocrit; *STIs,* sexually transmitted infections.

TABLE 5-10 NURSING ASSESSMENT

Mistreatment

- Screen for possible elder mistreatment, including domestic violence.
- Conduct a thorough history and head-to-toe assessment. Document your findings, including any statements made by the older adult or accompanying adult.
- If the older adult appears to be in immediate danger, develop and implement a safety plan in collaboration with the interdisciplinary team involved in the person's care.
- Identify, collect, and preserve physical evidence (e.g., dirty or bloody clothing, dressings, or sheets).
- After obtaining consent, take photographs to document physical findings of suspected abuse or neglect. If possible and appropriate, do this before treating or bathing the alleged victim.
- If you suspect that mistreatment is occurring, report your findings to the appropriate state agency and/or law enforcement as mandated by the laws in your state.
- Initiate social work, forensic nursing, and other consultations as appropriate.

Medicare has four options for coverage: A, B, C, and D. Part A covers inpatient hospital care and partially covers skilled nursing facility care, hospice, and home health care. Part A coverage is "free" because workers support Medicare through payroll taxes.[35] Medicare Part B partially covers outpatient care, physicians' services, and home health care. It also covers some preventive services, such as mammograms. Medicare Part B is voluntary and has a monthly premium and an annual deductible before payment begins. Medicare Advantage Plans, sometimes called "Part C" or "MA Plans," are offered by private companies approved by Medicare to provide Part A and Part B benefits. Part D is available to Medicare enrollees and provides a prescription drug benefit. Members pay a yearly deductible, a monthly premium, and a copayment. People with lower incomes and limited assets may qualify for extra help to pay for prescriptions.

Medicare does not cover long-term care, custodial ADLs or IADLs care, dental care or dentures, hearing aids, or eyeglasses. (More information is available at *www.Medicare.gov.*) These costs, plus the Medicare deductible, account for the fact that some older adults pay for 50% of their health care costs yearly.

Medicaid is a state-administered, needs-based program to assist eligible low-income people, including Medicare beneficiaries, with certain medical expenses. Individuals who qualify for both Medicare and Medicaid are frequently referred to as "dual-eligibles." Eligibility and coverage vary by state. For Qualified Medicare Beneficiaries, Medicaid pays Medicare premiums, deductibles, and co-insurance, as well as long-term care and home health expenses. In the United States the majority of long-term care is paid for by Medicaid or private pay. (More information is available at *www.medicaid.gov.*)

CARE ALTERNATIVES FOR OLDER ADULTS

Older adults with special care needs include people who are homeless, in need of assistance with ADLs, cognitively impaired, homebound, or no longer able to live at home. Older adults may

be served by adult day care, adult day health care, home health care, and long-term care.

Adult Day Care and Adult Day Health Care

Adult day care centers provide social, recreational, and health-related services to individuals in a safe, community-based environment (Fig. 5-5). This includes daily supervision, social activities, opportunities for social interaction, and ADLs assistance for two major groups of adults: those who are cognitively impaired, and those who have problems independently performing ADLs. Services offered in adult day care programs are individualized based on need. Programs designed for adults who are cognitively impaired offer therapeutic recreation, support for family, family counseling, and social involvement.

Adult day health care centers are similar to adult day care but are designed to meet the needs of older adults and people with disabilities who need a higher level of care. This might include health monitoring, therapeutic activities, one-on-one ADLs training, and personal services.

Adult day care centers and adult day health care centers may provide respite to allow continued employment for the caregiver and delay institutionalization of older adults. Centers are regulated, and standards are set by the state. Medicare does not cover costs. Adult day health care is tax deductible as dependent care. Appropriate placement in adult care programs that match participants' needs is important. Caregivers and adults with self-care deficits are often uninformed about adult day centers and their services as an alternative care option. You can assist by knowing the available centers in your area and assessing the needs of older adults and their families. You will then be in a position to assist older adults and their families in making good decisions about their care.

Home Health Care. Home health care (HHC) can be a cost-effective care alternative for older adults who are homebound, have health needs that are intermittent or acute, and have supportive caregiver involvement. HHC is not an alternative for adults in need of 24-hour ADLs assistance or continuous safety supervision. (Private duty care may be an alternative in these situations.) HHC services require physician orders and skilled nursing care for Medicare reimbursement. Unless these requirements are met, assistance by home health aides for ADLs management or assistance by a homemaker for IADLs management will not be paid by Medicare.

In addition to HHC, respite, personal care, and homemaker services are often sought by caregivers through organizations that provide nonmedical assistance. These services help older adults stay at home.

Long-Term Care Facilities

Practice settings for long-term care are presented in eTable 1-2. Three factors appear to precipitate placement in a long-term care facility: (1) rapid patient deterioration, (2) caregiver inability to continue care because of stress and burnout, and (3) an alteration in or loss of the family support system. Deteriorating cognition, incontinence, or a major health event (e.g., stroke) can accelerate placement.

The conflicts and fears faced by older adults and their families make placement a difficult transition. Common caregiver concerns include: (1) Will the older adult resist the admission process?; (2) Will the level of care given by staff be insufficient?; (3) Will the resident be lonely?; and (4) Will nursing care be affordable?

This time of disruption is exacerbated by the physical relocation of the older adult and may result in adverse health effects for them. *Relocation stress syndrome* is a nursing diagnosis that is associated with the disruption, confusion, and challenges that older adults face when moving from one environment to a new environment. Older adults may experience anxiety, depression, and disorientation. Appropriate interventions can reduce the effects of relocation. Whenever possible, involve older adults in the decision to move and fully inform them about the location. Caregivers can share information, pictures, or a video recording of the new location. Personnel at the institution can send a welcome message. On arrival, new residents can be greeted by staff members to provide orientation. To bridge the relocation, new residents can be "buddied" with seasoned residents (Fig. 5-6).

LEGAL AND ETHICAL ISSUES

Legal assistance is a concern for many older adults. Legal concerns include advance directives, estate planning, taxation issues, appeals for denied services (e.g., disability), financial decisions, or exploitation by strangers or "trusted others." Legal aid is available to older adults with low income by contacting a local senior center.

FIG. 5-5 Senior centers offer places for older adults who live independently to meet and gather with friends. (Jupiterimages/Comstock/Thinkstock)

FIG. 5-6 Social interaction and acceptance are important for older adults. (Hemera/Thinkstock)

Advance directives are written statements of a person's wishes regarding medical care. These documents allow patients to more specifically direct their own care at end of life. Advance directives are discussed in detail in Chapter 10 and Table 10-6.

When working with older adults, you may find several ethical issues that influence practice, such as use of physical or chemical restraints or the assessment of older adults' ability to make decisions. Other ethical issues related to end-of-life care include decisions about resuscitation, treatment of infections, nutrition and hydration, and transfer to more intensive treatment units. These situations are often complex and emotionally charged. You can assist the patient, family, and other health care workers by (1) acknowledging when an ethical dilemma is present, (2) keeping current on the ethical issues, and (3) advocating for an institutional ethics committee to help in the decision-making process.

NURSING MANAGEMENT OLDER ADULTS

Gerontologic nursing is the care of older adults based on the specialty body of knowledge of gerontology and nursing. These specialty nurses approach older adults with a whole-person (physical, psychologic, developmental, socioeconomic, cultural) perspective. Care of older adults is complex and presents challenges that require skilled assessment and creative nursing interventions tailored to this population.

Diseases and conditions in older adults may be difficult to accurately assess and diagnose. Older adults may underreport symptoms and "treat" these symptoms by altering their functional status. For example, a man having loss of feeling in his feet because of neuropathy may start using a walker to get around. At the same time, he does not report the symptom to his health care provider. The older adult may attribute a new symptom to "aging" and ignore it. The older adult may eat less, sleep more, or "wait it out."

In older adults, disease symptoms are often atypical. Complaints of an "aching joint" may actually be a broken hip. Asymptomatic cardiac disease may be diagnosed when the patient is being treated for a urinary tract infection. Pathologic conditions with similar symptoms are often confused. For example, depression may be misdiagnosed and treated as dementia.

In older adults a *cascade disease pattern* may occur. For example, a patient who experiences insomnia treats the condition with a hypnotic medication, becomes lethargic and confused, falls, breaks a hip, and subsequently develops pneumonia. You play a vital role in preventing this downward trajectory.

Older adults may face health problems with fear and anxiety. They may view health care workers as helpful, but perceive institutions as negative and potentially harmful places. Communicate a sense of concern and care by use of direct and simple statements, appropriate eye contact, direct touch, and gentle humor. These actions help the older adult relax in this stressful situation.

NURSING ASSESSMENT

Before beginning the assessment process, first attend to primary needs. For example, make certain that the patient is comfortable and does not need to urinate. Place all assistive devices, such as glasses and hearing aids, within reach. Evaluate your patient's level of fatigue and stop the interview if necessary. Allow adequate time to offer information to the patient and time for the patient to respond to questions. Interview both the older adult and his or her family or caregivers. This can be done separately unless the patient is cognitively impaired or specifically requests the caregiver's presence. The medical history may be lengthy. Review medical records and determine what information is relevant.

The focus of a comprehensive geriatric assessment is to determine appropriate interventions to maintain and enhance the functional abilities of older adults. Comprehensive geriatric assessment is interdisciplinary and, at a minimum, includes the medical history, physical examination, functional assessment, medication review, cognitive and mood evaluation, and social resources. Comprehensive geriatric assessment is often conducted by an interdisciplinary geriatric assessment team. The interdisciplinary team may include many disciplines, but at least a nurse, a physician, and a social worker. After the assessment is complete, the interdisciplinary team meets with the patient and family to present the team's findings and recommendations.[32]

Elements in a comprehensive nursing assessment include a history using a functional health pattern format (see Chapter 3), physical assessment, mood assessment, assessment of ADLs and IADLs, mental status evaluation, and a social-environmental assessment. Evaluation of mental status is particularly important for older adults because these results often determine the potential for independent living. SPICES, an effective tool for obtaining assessment data in older adults, should be the basis of nursing assessment when working in any setting (Fig. 5-7).

Evaluation of the results of a comprehensive nursing assessment helps determine the service and placement needs of older adults. Collect data regarding community resources that are needed to assist older adults and their caregivers in maintaining maximal functioning. The goal is to plan and implement actions that help older adults remain as functionally independent as possible.

PLANNING

When setting goals with older adults, it is helpful to identify their strengths and abilities. Include caregivers in planning. Priority goals for older adults might include gaining a sense of control, feeling safe, and reducing stress.

NURSING IMPLEMENTATION

When carrying out a plan of action for older adults, modify your approach and actions based on their physical and mental status. Small body size, common in older adults who are frail,

Patient name:	Date:	
	EVIDENCE	
SPICES	Yes	No
Sleep disorders		
Problems with eating or feeding		
Incontinence		
Confusion		
Evidence of falls		
Skin breakdown		

FIG. 5-7 SPICES.

may necessitate the use of pediatric equipment (e.g., blood pressure cuff). As with all patient groups, safety is a primary concern when caring for an older adult. Bone and joint changes often require transfer assistance, altered positioning, and use of gait belts and lift devices. Older adults with declining energy reserves may require additional time to complete tasks. A slower approach and the use of other adaptive equipment may be necessary.

Cognitive impairment, if present, requires that you offer careful explanations and a calm approach to avoid producing anxiety and resistance in the older adult. Depression can result in apathy and poor cooperation with the treatment plan.

HEALTH PROMOTION. Health promotion and prevention of health problems for older adults focus on three areas: (1) reduction in diseases and problems, (2) increased participation in health promotion activities (Fig. 5-8), and (3) increased targeted services that reduce health hazards. Programs have been successfully developed for screening for chronic health conditions, tobacco cessation, geriatric foot care, vision and hearing screening, stress reduction, exercise programs, drug usage, crime prevention, elder mistreatment, and home hazards assessment. You can carry out and teach older adults about the need for specific preventive services.

Health promotion and prevention can be included in nursing interventions at any location or level where nurses and older adults interact. You can use health promotion activities to increase self-care, personal responsibility for health, and independent functioning that will enhance the well-being of older adults. Resources available to you are listed at the end of the chapter. Teaching is an important tool for you to use to enhance self-care practices by older adults. (Patient teaching is discussed in Chapter 4.)

ACUTE CARE. Frequently the hospital is the first point of contact for older adults and the formal health care system. Conditions that most commonly result in hospitalization include falls, dysrhythmias, heart failure, stroke, fluid and electrolyte imbalances (e.g., hyponatremia, dehydration), pneumonia, urosepsis, and hip fractures. Older adults are often hospitalized with multiple system problems.

When older adults are being cared for in the acute care setting, both patients and caregivers need assistance with a variety of functions (Table 5-11). The outcome of hospitalization for older adults varies. Of particular concern are problems of high surgical risk, acute confusional state, health care–associated infection, and premature discharge in an unstable condition. Geriatric nursing considerations sections throughout this book emphasize special needs and interventions for older adult patients.

Care Transitions. At the time of a care transition to another setting (e.g., acute care hospital to rehabilitation), many older adults are in an unstable condition. (Transitional care settings are presented in eTable 1-1.) Frail older adults and patients over 85 years of age are particularly vulnerable during care transitions. Most of these patients are transitioned under Medicare regulations that require a registered nurse or qualified person to develop a plan for discharge. Care transition plans are periodically reassessed, and caregivers and patients must be counseled to prepare the patient for posthospital care. Safe, effective, and efficient care transitions are most likely to occur when interdisciplinary team members work together to coordinate care.

Rehabilitation. The goal of rehabilitation is to help older adults adapt to or recover from disability. Rehabilitation may occur in acute inpatient rehabilitation or long-term care settings. With proper training, assistive equipment, and attendant personal care, people with disabilities often live independently. Older adults, primarily through Medicare reimbursement, can receive rehabilitative assistance through acute inpatient rehabilitation (limited days) and home health care programs (Fig. 5-9).

TABLE 5-11 CARE OF THE HOSPITALIZED OLDER ADULT

- Identify adults over age 85 with or without frailty and patients at risk for iatrogenic (due to medical/surgical treatment) problems.
- Consider discharge needs early in the hospital stay, especially assistance with ADLs, IADLs, and medications.
- Encourage the development and use of interdisciplinary teams, special care units, and individuals who focus on the special needs of older patients.
- Implement standard protocols to screen for at-risk conditions commonly present in the hospitalized older adult, such as urinary tract infection and delirium.
- Implement mobility programs to prevent functional decline. ("The bed is not your friend.")
- Advocate for referral of the patient to appropriate community-based services.

ADLs, Activities of daily living; *IADLs,* instrumental activities of daily living.

FIG. 5-8 Water aerobics is an example of a health promotion activity for older adults. (Jupiterimages/Photos.com/Thinkstock)

FIG. 5-9 The nurse assists a patient in a geriatric rehabilitation facility. (Keith Brofsky/Photodisc/Thinkstock)

Older adults with chronic conditions, such as stroke, arthritis, and heart disease, have increased risk of becoming functionally limited. These disabilities lead to increased self-care deficits, higher mortality rates, increased rates of institutionalization, and decreased life span. Reducing disability through geriatric rehabilitation is important to the quality of life of older adults.

Often older adults have specific fears and anxieties related to falling. Older adults are limited in the rehabilitation process by sensory-perceptual deficits, other health problems, impaired cognition, poor nutrition, and financial problems. Encouragement, support, and acceptance from all members of the health care team and their caregivers can assist older adults in remaining motivated for the hard work of rehabilitation.

Rehabilitation of older adults is influenced by several factors. First, preexisting problems associated with reaction time, visual acuity, fine motor ability, physical strength, cognitive function, and motivation affect the rehabilitation potential of older adults.

Second, older adults often lose function because of inactivity and immobility. This *deconditioning* can occur as a result of unstable acute medical conditions, environmental barriers that limit mobility, and a lack of motivation to stay in condition. The effect of inactivity clearly leads to "use it or lose it" consequences. Older adults can improve flexibility, strength, and aerobic capacity even into very old age. Passive and active range-of-motion exercises are used with all older adults to prevent deconditioning and subsequent functional decline.

Last, the goal of rehabilitation is to strive for maximal function and physical capabilities considering the individual's current health status. When an older adult demonstrates suboptimal health, screen and evaluate for risk behaviors. For example, on admission to any acute or long-term care facility and home health services, assess for fall risk, initiate appropriate fall prevention interventions, and evaluate for ongoing risk. Conduct accurate and comprehensive foot assessments for older adults with diabetes and arrange appropriate follow-up care.

Assistive Devices. Consider the use of assistive devices as interventions for older adults. Using appropriate assistive devices such as dentures, glasses, hearing aids, walkers, wheelchairs, adult briefs or protectors, adaptive utensils, elevated toilet seats, and skin protective devices can decrease disability. Include these tools and devices in the older adult's care plan when appropriate, and provide instruction in the proper use of the devices. For example, using a cane inappropriately may increase the risk for a fall.

Technology can assist with rehabilitation and living with functional impairments.[36] For example, electronic monitoring equipment can be used to monitor heart rhythms and blood pressure. Monitoring can also locate a person with dementia who has wandered away from home or a long-term care facility. Computerized assistive devices can be used to help patients with speech difficulties following stroke, and small electronic devices can serve as memory aids.

Safety. Safety is crucial in the health maintenance of older adults. When compared to younger adults, older adults are at higher risk for accidents because of normal sensory changes, slowed reaction time, decreased thermal and pain sensitivity, changes in gait and balance, and medication effects. Most accidents occur in or around the home. Falls, motor vehicle accidents, and fires are common causes of accidental death in older adults. Another environmental problem arises from the older person's impaired thermoregulation system that cannot adapt to extremes in environmental temperatures. The bodies of older adults can neither conserve nor dissipate heat as efficiently as younger adults. Therefore both hypothermia and hyperthermia occur more readily. This age-group accounts for the majority of deaths during severe cold spells and heat waves.

You can provide valuable counsel regarding environmental changes, which may improve safety for older adults. Measures such as colored step strips, tub and toilet grab bars, and stairway handrails can be effective in "safety-proofing" the living spaces of older adults. You can also advocate for home fire and security alarms. Uncluttered floor space, railings, and increased lighting and night-lights are some of the easiest and most practical adaptations.

Older adults who are new to inpatient or long-term care settings need a thorough orientation to the environment. Reassure the older adult that he or she is safe, and attempt to answer all questions. Foster orientation by displaying large-print clocks, avoiding complex or visually confusing wall designs, clearly designating doors and exits, and using simple bed and nurse-call controls. Provide diffuse lighting while avoiding glare. Environments that provide consistent caregivers and an established daily routine increase an older adult's sense of comfort and safety.

Medication Use. Medication use in older adults requires thorough and regular assessment, care planning, and evaluation. Nonadherence to medication regimens by older adults is common. Four of ten older adults are unable to read prescription drug labels, and two thirds are unable to understand the health information that is provided to them.[37]

Age-related changes alter the pharmacodynamics and pharmacokinetics of drugs. Drug-drug, drug-food, and drug-disease interactions all influence the absorption, distribution, metabolism, and excretion of drugs. The most dramatic changes with aging are related to drug metabolism (Fig. 5-10). Overall, by age 75 to 80, there is a 50% decline in the renal clearance of drugs. Hepatic blood flow decreases markedly with aging, and the enzymes largely responsible for drug metabolism are decreased as well. As a result, drug half-life is increased in older adults as compared with younger adults. This leads to drug toxicity and adverse drug events.

In addition to changes in the metabolism of drugs, older adults may have difficulty due to cognitive impairment, altered sensory perceptions, limited hand mobility, and the high cost of many prescriptions. Common reasons for drug errors made by older adults are listed in Table 5-12. *Polypharmacy* (the use of multiple medications by a person who has more than one health problem), overdose, and addiction to prescription drugs are recognized as major causes of illness in older adults.[37]

The effects of medications in older adults with multiple health problems are particularly challenging to assess and manage. As one disease is treated, another may be affected. For

TABLE 5-12 DRUG THERAPY

Common Causes of Medication Errors by Older Adults

- Decreased vision
- Forgetting to take drugs
- Use of nonprescription over-the-counter drugs
- Use of medications prescribed for someone else
- Lack of financial resources to obtain prescribed medication
- Failure to understand instructions or importance of drug treatment
- Refusal to take medication because of undesirable side effects

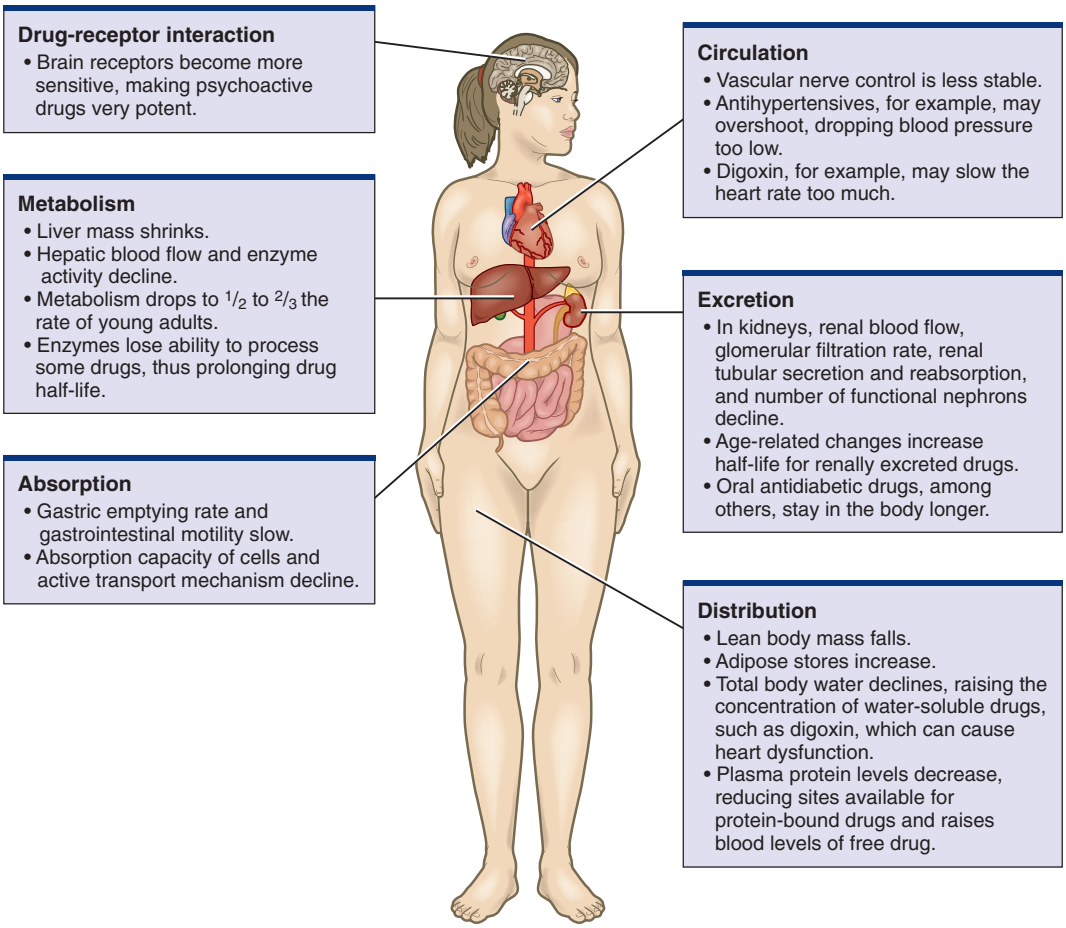

FIG. 5-10 The effects of aging on drug metabolism.

example, the use of a drug such as oxybutynin (Ditropan), which is prescribed for overactive bladder, may cause confusion. To accurately assess medication use and knowledge, ask older adults to bring all medications (over-the-counter drugs, prescription drugs, vitamins and supplements, and herbal remedies) that they take regularly or occasionally to their health care appointment. You will then be able to accurately assess all medications the patient is taking, including drugs that the person may have omitted or thought unimportant. Additional nursing interventions to assist older adults in following a safe medication routine are listed in Table 5-13.

Depression. Depression is not a normal part of aging. However, it is often an underrecognized problem in older adults. Approximately 15% of older adults living in their homes have symptoms of depression. Rates of depressive symptoms in older adults in institutional settings are higher. Older adults commit 20% of the suicides in the United States, and older men who are white have the highest rate of suicide.[38]

Depression is associated with female gender, divorced or separated marital status, low socioeconomic status, poor social support, and a recent adverse and unexpected event. Depression in older adults tends to arise from a loss of self-esteem and may be related to life situations, such as retirement or loss of a spouse or partner. Problems such as physical complaints, insomnia, lethargy, agitation, weight loss, decreased memory, and inability to concentrate are common.

Late-life depression often co-occurs with medical conditions, such as heart disease, stroke, diabetes, and cancer. Depression can exacerbate medical conditions by affecting adherence

TABLE 5-13 DRUG THERAPY

Medication Use by Older Adults

- Evaluate cognitive function and ensure ability to self-administer medication.
- Attempt to reduce medication use that is not essential by consulting the health care provider and pharmacist.
- Assess medication use, including prescription drugs; over-the-counter drugs; antihistamines; cough syrups; vitamins, minerals, and supplements; and herbal remedies.
- Assess alcohol and illicit drug use.
- Encourage the use of written or electronic medication-reminder systems.
- Encourage the use of one pharmacy.
- Work with health care providers and pharmacists to establish routine drug profiles on all older adult patients.
- Advocate (with drug companies) for low-income prescription support services.

with diet, exercise, or drug regimens. It is important that your assessment include physical examination and interpretation of laboratory results for physical disorders that may have symptoms similar to those of depression (e.g., thyroid disorders, vitamin deficiencies). The Geriatric Depression Scale is easy to administer and is the gold standard assessment tool (see eTable 5-1 on the website for this chapter).

Encourage older adults who exhibit depressive symptoms to seek treatment. Because older adults with depression may feel unworthy, withdrawn, and isolated, the support of the family or others in encouraging older adults to seek treatment is important. Assist older adult caregivers who exhibit depressive symptoms to seek medical attention, and assist them in securing respite services and support for their caregiving role. (Family caregiving is discussed in Chapter 4 on pp. 50 to 52.)

Use of Restraints. *Physical restraints* are devices, materials, and equipment that physically prevent individuals from moving freely, such as walking, standing, lying, transferring, or sitting. *Chemical restraints* are medications that prevent a patient's voluntary movement.

Restraints may be used only to ensure the person's safety or the safety of others. Physical and chemical restraints are a last resort in the care of older adults. If physical or chemical restraints are used in the hospital or long-term care setting, use of the least restrictive restraint is required. Restraints require an order from a physician or an independently licensed advance practice nurse. In addition, frequent scheduled reviews of the ongoing necessity of the restraint are needed. There are additional regulatory requirements for restraint use, including time limit, observation and care, and alternatives to the use of restraints. Long-term care regulations and The Joint Commission set standards for restraint usage.

Carefully document restraint use and the behaviors that require this intervention. It is not appropriate to use restraints based on fall risk or irritating behaviors, such as calling out. The current standard is to provide safe care without using restraints of any form, whether physical or chemical.[39]

To achieve this standard, evaluate the patient's behavior. Behavioral symptoms, such as crying and shouting, may arise from co-morbidities, pain, medication toxicity, unmet needs, or environmental factors. When behavioral symptoms are evident, ask the following questions to better understand the patient's behavior: Is the person able to verbalize what she or he needs and wants? People with dementia may respond by speaking, gesturing, nodding, or making eye contact.[38] Questions that use "yes" or "no" answers are better than open-ended questions for gathering assessment information. Ask family, friends, or staff members from previous care settings about the patient's history; usual communication style and cues to indicate pain, fatigue, hunger, or a need to urinate or defecate; abilities in ADLs; and daily routines (e.g., "Is he often awake at night or an early riser?" "Does she prefer breakfast before dressing? Take an afternoon nap? Have a routine for dressing?").

Evaluate whether disruptive behaviors signal unmet physiologic or psychosocial needs. For example, a patient who tries to get out of bed without help may be trying to reach the toilet. A toileting schedule will help to curtail such attempts and prevent incontinence. In critical care settings, patients emerging from sedation may be alarmed by an inability to speak or the presence of inserted tubes. Consider how treatments feel to the patient and pay attention to gestures, actions, and words to ascertain their meaning.

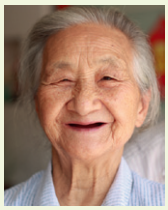
Restraint alternatives require vigilant, creative, and sensitive nursing care. Restraint alternatives include low beds, body props, and electronic devices (such as bed alarm signaling). Such approaches support the development of a "restraint-free" environment.

Sleep. Adequacy of sleep is often a concern for older adults because of altered sleep patterns. Older people experience a marked decrease in deep sleep and are easily aroused. Many older adults report difficulty initiating sleep and maintaining prolonged sleep; they may state they feel "unrefreshed" after sleep. (Sleep problems of older adults are discussed in Chapter 8.)

EVALUATION

The evaluation phase of the nursing process is similar for all patients. The results of evaluation direct you to continue the plan of care or revise as indicated. When evaluating nursing care with older adults, focus on functional improvement. Useful questions to consider when evaluating the plan of care for older adults are included in Table 5-14.

TABLE 5-14 EVALUATING NURSING CARE FOR OLDER ADULTS



Use the following questions to evaluate the effectiveness of care for older adults.

- Is there an identifiable change in ADLs, IADLs, mental status, or disease signs and symptoms?
- Does the patient consider his or her health state to be improved?
- Does the patient think the treatment is helpful?
- Do the patient and caregiver think the care is worth the time and cost?
- Can you document positive changes that support the interventions?
- Does change adequately meet the required mandates for reimbursement?

ADLs, Activities of daily living; *IADLs*, instrumental activities of daily living.

CASE STUDY

Older Adults

iStockphoto/Thinkstock

Patient Profile

L.X., a 79-year-old Chinese woman, was admitted through the emergency department with shortness of breath. She was diagnosed with community-acquired pneumonia. Her history also indicates she has chronic obstructive pulmonary disease (COPD), hypertension, diabetes, mild cognitive impairment, depression, macular degeneration, and significant hearing loss.

Subjective Data

- Had a stroke 5 years ago and has right-sided weakness
- Has a 100 pack-year history of tobacco use but quit smoking after her stroke
- Has not seen primary care physician in 1 year
- In past year has had an unplanned weight loss of 20 pounds
- Spends her days either in bed or in a recliner watching television

Psychosocial Data

- Came to the United States 15 years ago from China.
- Speaks Mandarin with limited English proficiency.
- Lives with her unemployed adult son who provides assistance with ADLs and IADLs.
- Has three daughters who live within a 2-hour drive.
- Has limited financial resources but has Medicare and Medicaid benefits.
- Her son has not visited her in the hospital, but her daughters raise concerns about their mother's care and safety at home, given their brother's history of anger issues and a gambling addiction.
- When daughters ask their brother about how he is caring for his mother, he says, "I'm doing the best I can. She refuses help. She refuses to go to the doctor. What do you want me to do? She's old. She's crazy. She's going to die anyway!"

Objective Data

- Matted hair, poor oral hygiene, overgrown toenails
- Two stage III sacral ulcers
- Unstageable right heel ulcer
- Multiple small bruises on her forearms and shins
- 5 × 10-cm bruise in the middle of her back

Discussion Questions

1. Compare L.X.'s experience as an older woman to known gender differences for older adults.
2. Identify the stage(s) of Corbin and Strauss chronic illness trajectory that describe L.X.'s current status. Which stage(s) is the goal of your nursing care?
3. Given the tasks of people with chronic illness as described by Corbin and Strauss, what is your assessment of L.X.'s ability to successfully complete these tasks? What will you include in your care planning to optimize her ability to complete these tasks?
4. Define *ageism,* and explain how it may be manifested in this case.
5. What risk factors does L.X. have for development of frailty? Which of these factors are modifiable?
6. ***Priority Decision:*** Based on your assessment of L.X., what are the priority nursing diagnoses?
7. ***Priority Decision:*** What are the priority nursing interventions for L.X.?
8. Explain ethnogeriatrics considerations that affect L.X. and how they will influence your nursing care.
9. Based on your knowledge of care alternatives for older adults, what setting(s) might be appropriate for L.X. on hospital discharge?
10. What risk factors does L.X. have for becoming a victim of elder mistreatment?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg.*

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Examples of primary prevention strategies include
   - **a.** colonoscopy at age 50.
   - **b.** avoidance of tobacco products.
   - **c.** intake of a diet low in saturated fat in a patient with high cholesterol.
   - **d.** teaching the importance of exercise to a patient with hypertension.
2. A characteristic of a chronic illness is that it *(select all that apply)*
   - **a.** has reversible pathologic changes.
   - **b.** has a consistent, predictable clinical course.
   - **c.** results in permanent deviation from normal.
   - **d.** is associated with many stable and unstable phases.
   - **e.** always starts with an acute illness and then progresses slowly.
3. Ageism is characterized by
   - **a.** denial of negative stereotypes regarding aging.
   - **b.** positive attitudes toward the elderly based on age.
   - **c.** negative attitudes toward the elderly based on age.
   - **d.** negative attitudes toward the elderly based on physical disability.
4. An ethnic older adult may feel a loss of self-worth when the nurse
   - **a.** informs the patient about ethnic support services.
   - **b.** allows a patient to rely on ethnic health beliefs and practices.
   - **c.** has to use an interpreter to provide explanations and teaching.
   - **d.** emphasizes that a therapeutic diet does not allow ethnic foods.
5. An important nursing action to help a chronically ill older adult is to
   - **a.** avoid discussing future lifestyle changes.
   - **b.** assure the patient that the condition is stable.
   - **c.** treat the patient as a competent manager of the disease.
   - **d.** encourage the patient to "fight" the disease as long as possible.
6. Older adults who become ill are more likely than younger adults to
   - **a.** complain about the symptoms of their problems.
   - **b.** refuse to carry out lifestyle changes to promote recovery.
   - **c.** seek medical attention because of limitations on their lifestyle.
   - **d.** alter their daily living activities to accommodate new symptoms.

7. An appropriate care choice for an older adult who lives with an employed daughter but requires help with activities of daily living is
   a. adult day care.
   b. long-term care.
   c. a retirement center.
   d. an assisted living facility.

8. Nursing interventions directed at health promotion in the older adult are primarily focused on
   a. disease management.
   b. controlling symptoms of illness.
   c. teaching positive health behaviors.
   d. teaching regarding nutrition to enhance longevity.

1. b, 2. c, d, 3. c, 4. d, 5. c, 6. d, 7. a, 8. c.

LEARNING OUTCOMES

1. Compare and contrast the conventional model and the integrative model for health care.
2. Describe four categories of complementary and alternative therapies.
3. Choose the key concepts to include when teaching patients about herbal supplements.
4. Name three commonly used herbal products and their indications for use.
5. Describe the nurse's role related to complementary and alternative therapies.
6. Explain how the nurse can assess a patient's use of complementary and alternative therapies.
7. Describe ways that the nurse can use complementary and alternative therapies to provide self-care.

KEY TERMS

acupuncture, p. 83
complementary and alternative therapies, p. 80
herbal therapy, p. 81
holistic nursing, p. 80
massage, p. 83

Historically wellness has been viewed as incorporating the physical, emotional, mental, and spiritual realms. Hippocrates, the father of medicine, advised a daily aromatic bath and fragrant massage for the maintenance of health. Florence Nightingale believed that nursing puts patients in the best condition for nature to act on them. The concepts of holism and balance guided the belief that the body heals itself and works to maintain homeostasis. The concepts of spirituality and harmony with nature were inseparable from the concepts of health and wellness.

This view of "wholeness" began to change with the works of René Descartes (1596–1650) and Sir Isaac Newton (1642–1727). They postulated that the body is a series of parts that can be broken down and studied. This mechanistic approach views the body as a machine; whatever part is broken is analyzed and then repaired, without regard for other aspects of the person involved. The *conventional model* of health care is based on this approach. Health care focuses on the physical body, often to the exclusion of the mind and the spirit. Emphasis is placed on what can be seen, measured, and quantified.

This conventional model has guided American health care for more than 100 years. About 40 years ago Americans began to explore health care therapies that were outside this model. This consumer-led movement fostered development of a new model of health care, a more "integrative" model. In this model, consumers combine the use of complementary and alternative therapies with conventional therapies. The conventional and integrative health care models are compared in Table 6-1.

The *integrative model* focuses on (1) personal responsibility for health; (2) joining of mind-body-spirit; and (3) use of natural, less invasive modalities. This model promotes health and wellness, not just treatment of diseases. Consumers desire more involvement in their health care decisions. They desire modalities that are more natural, less costly, and safer. The rise of chronic diseases and stress-related disorders has also led to consumers' interest in complementary and alternative therapies.

Reviewed by Jane A. Madden, RN, MSN, Professor of Nursing, Pikes Peak Community College, Colorado Springs, Colorado.

TABLE 6-1 COMPARISON OF CONVENTIONAL AND INTEGRATIVE HEALTH CARE MODELS

Conventional Health Care Model	Integrative Health Care Model
• Focus on physical body	• Focus on mind-body-spirit
• Focus on treatment of symptoms using medications and surgery	• Focus on self-healing of the body using herbs, exercise, nutrition, stress management
• Health care provider directs care	• Individual directs care; personal responsibility for health encouraged
• Focus on disease states	• Focus on health and wellness
• Technologic, invasive	• Noninvasive
• Increasing cost	• Lower cost
• Little focus on prevention	• Focus on prevention

COMPLEMENTARY AND ALTERNATIVE THERAPIES

Complementary and alternative therapies (CAT) are a group of diverse medical and health care systems, practices, and products that are not generally considered part of conventional medicine.[1] This definition highlights what might be considered "complementary and alternative" in one country or at one period of history might be considered "conventional" in another place or time. What is classified as complementary and alternative therapies is constantly changing. When these therapies are proven safe and effective, they are often adopted into conventional medicine.

Terms frequently used to describe health-related approaches that are outside the dominant system of health care include *alternative, complementary,* and *integrative. Alternative therapies* are therapies used in place of conventional medicine, whereas *complementary therapies* are used in conjunction with conventional medicine. *Integrative therapies* combine treatments from conventional medicine with complementary and alternative therapies that have evidence of safety and effectiveness.

Many complementary and alternative therapies are harmonious with the values of nursing. Nurses emphasize healing, recognize the provider-patient relationship as a partnership, and focus on health promotion and illness prevention. The American Holistic Nurses Association (AHNA) was established to focus nursing care on the whole person—recognizing the interconnectedness of body, mind, spirit, and environment. The AHNA highlights the practice of holistic nursing.

Holistic nursing is based on a body of knowledge; evidence-based research; sophisticated skill sets; defined standards of practice; and a philosophy of living and being that is grounded in caring, relationship, and interconnectedness.[2] AHNA *(www.ahna.org)* advances the profession of holistic nursing by providing continuing education in holistic nursing, helping to improve the health care workplace through the incorporation of the concepts of holistic nursing, educating professionals and the public about holistic nursing and integrative health care, and promoting research and scholarship in the field of holistic nursing.[3]

Health care professionals have raised important questions about the effectiveness and safety of complementary and alternative approaches in the face of their increased use. In response to this need, the National Center for Complementary and Alternative Medicine (NCCAM) was established *(http://nccam.nih.gov)*. A branch of the National Institutes of Health (NIH), NCCAM serves as the federal government's lead agency for scientific research on complementary and alternative therapies. The mission of NCCAM is to define, through rigorous scientific investigation, the usefulness and safety of complementary and alternative medicine interventions and their roles in improving health and health care.[4]

NCCAM has four areas of focus: (1) advancing scientific research, (2) training CAM researchers, (3) sharing news and information, and (4) supporting integration of proven CAM therapies. The website provides a wealth of information for consumers and professionals, including clinical practice guidelines and literature reviews for the health care professional.

A large study conducted by NCCAM and the National Center for Health Statistics (as a part of the National Health Interview Survey [NHIS]) showed that approximately 38% of adults used CAT within the past 12 months.[5] In another survey Americans were asked why they use CAT, and 55% responded they believed their health would be improved if conventional medical treatments were combined with CAT.[6] Because of this growing use of CAT, you need to have a basic understanding of this topic and know where to find reliable in-depth information. A list of helpful websites is provided at the end of the chapter.

NCCAM CATEGORIES

Because the field of CAT is broad and ever changing, it is helpful to place therapies into broad categories. NCCAM groups these therapies into four broad categories, recognizing that one therapy may fit into more than one category (Table 6-2).

TABLE 6-2 NCCAM CATEGORIES OF COMPLEMENTARY AND ALTERNATIVE THERAPIES

Category	Description	Examples
Natural products	Practices that use substances found in nature for their impact on health and wellness.	Herbal therapy, dietary supplements, vitamins, minerals, probiotics, aromatherapy
Mind-body medicine	Techniques that enhance mind's ability to affect the physical body. Science of psychoneuroimmunology demonstrates strength of mind-body connection.	Meditation, yoga, acupuncture, relaxation breathing, guided imagery, hypnotherapy, prayer, journaling, art therapy
Manipulative and body-based practices	Practices that are based on the manipulation and/or movement of one or more parts of the body.	Massage, chiropractic therapy, yoga
Other CAT practices	Wide variety of practices.	Movement therapies (e.g., Pilates), traditional healers, manipulation of energy fields (e.g., Healing Touch), whole medical systems (Table 6-3)

CAT, Complementary and alternative therapies; *NCCAM,* National Center for Complementary and Alternative Medicine.

Natural Products

The category of natural products includes herbal therapy, dietary supplements, vitamins, minerals, and other "natural products." The NHIS found that 17.7% of American adults had used a natural product in the previous year. These products were the most commonly used CAT.[5]

Herbal therapy is the use of individual herbs or combinations of herbs for therapeutic benefit. An *herb* is a plant or plant part (bark, roots, leaves, seeds, flowers, or fruit) that produces and contains chemical substances that act on the body. It is estimated that approximately 25,000 plant species are used medicinally throughout the world, and approximately 30% of modern prescription drugs are derived from plants. Botanical medicine is the oldest form of medicine; archaeologic evidence suggests that Neanderthals used plant-based remedies 60,000 years ago. Today about 80% of the world's population relies extensively on plant-derived remedies.

Medicinal plants work in much the same way as drugs; both are absorbed and trigger biologic effects that can be therapeutic. Many have more than one physiologic effect and thus have more than one condition for which they can be used. The range of action of herbs is extensive.

Overall the use of herbal therapy continues to increase. Although most herbal products can safely be used without professional assistance, side effects and interactions with prescription drugs have been described. There is concern that side effects from the use of herbal products are underreported, thus promoting the impression that herbal products are completely safe to use.

Because consumers tend not to share their use of herbal products with their primary health care provider, herb-drug interactions may also be underreported. Patients who are scheduled for surgery should be advised to stop taking herbal products 2 to 3 weeks before surgery. Patients who are being treated with conventional drug therapy should be advised to discontinue herbal products with similar pharmacologic effects because the combination may lead to an excessive reaction or to unknown interaction effects. Patient teaching guidelines related to herbal therapy are presented in Table 6-4.

TABLE 6-3 WHOLE MEDICAL SYSTEMS

Examples	Description
Traditional Chinese Medicine (TCM)	Based on restoring and maintaining balance of vital energy *(Qi)*. One of the world's oldest, most complete medical systems.
Ayurveda	Based on balance of mind, body, and spirit. Developed in India. Views disease as an imbalance between a person's life force *(prana)* and basic metabolic condition *(dosha)*.
Homeopathy	Based on "like cures like." Remedies are specially prepared from the same substance that causes the symptom or problem. Extremely small amounts of the substance are used for the remedy. Remedies are believed to work through an energy transfer.
Naturopathy	Based on promotion of health rather than symptom management. Focuses on enhancing the body's natural healing response using a variety of individualized interventions such as nutrition, herbology, homeopathy, physical therapies, and counseling. Naturopathic physicians are graduates of accredited naturopathic medical schools, and licensing varies by state.

TABLE 6-4 PATIENT & CAREGIVER TEACHING GUIDE

Herbal Therapies

- Ask the patient about use of herbal therapies. Take a complete history of herbal use, including amounts, brand names, and frequency of use. Ask the patient about allergies.
- Investigate whether herbs are used instead of or in addition to traditional medical treatments. Find out whether herbal therapies are used to prevent disease or to treat an existing problem.
- Instruct the patient to inform health care provider before taking any herbal treatments.
- Make the patient aware of the risks and benefits associated with herbal use, including drug reactions when taken in combination with other drugs.
- Advise the patient using herbal therapies to be aware of any side effects while taking herbal treatments and to immediately report them to health care provider.
- Make the patient aware that moisture, sunlight, and heat may alter the components of herbal treatments.
- Advise the patient to determine the reputation of the manufacturers of herbal products and the safety of the product before buying herbal treatments.
- Encourage the patient to read labels of herbal therapies carefully. Advise the patient not to take more of an herb than is recommended.
- Inform the patient that most herbal therapies should be discontinued at least 2 to 3 weeks before surgery.
- Inform the patient that the employees of health food stores are not trained health care professionals.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Complementary & Alternative Therapies Boxes Throughout Book

Information related to various complementary and alternative therapies can be found in the following boxes throughout the book.

Title	Chapter	Page
Acupuncture	65	1565
Assessment of Use of Herbs and Dietary Supplements	3	39
Biofeedback	46	1087
Echinacea	27	502
Fish Oil and Omega-3 Fatty Acids	33	716
Ginger	42	927
Glucosamine and Chondroitin	65	1565
Hawthorn	35	777
Herbal and Dietary Supplements That May Affect Clotting	38	851
Herbal Products and Surgery	18	320
Herbs and Supplements for Menopause	54	1285
Herbs and Supplements That May Affect Blood Glucose	49	1174
Imagery	52	1255
Kava	7	97
Lipid-Lowering Agents	34	738
Melatonin	8	104
Milk Thistle (Silymarin)	44	1012
Music Therapy	19	337
St. John's Wort	7	96
Yoga	6	83
Zinc	27	505

TABLE 6-5 COMMONLY USED HERBS*

Name	Uses Based on Scientific Evidence	Comments
Aloe	Constipation	• Short-term use only. • May cause electrolyte imbalances. • May lower blood glucose.
Cranberry	Prevention of urinary tract infection	• Drinking cranberry juice appears to be safe. • Excessive amounts can lead to gastrointestinal upset or diarrhea.
Echinacea	May reduce incidence and duration of upper respiratory tract infections	• Short-term use is recommended. • Use with caution in patients with conditions affecting immune system. • Use cautiously in patients with asthma because of increased risk of allergic reaction.
Evening primrose	Eczema, skin irritation	• Contraindicated in individuals with seizure disorders.
Feverfew	Migraine headache prevention	• May increase risk of bleeding. • Long-term users may experience withdrawal symptoms.
Garlic	May decrease cholesterol and low-density lipoproteins (studies have been inconsistent)	• May increase risk of bleeding. • May lower blood glucose.
Ginger	Nausea and vomiting of pregnancy	• May increase risk of bleeding. • May lower blood glucose. • Use in pregnancy should not exceed 1 g/day. • Supervision by health care provider is recommended for pregnant women considering use of ginger.
Ginkgo biloba	Symptoms of claudication	• Generally well tolerated in recommended dosages for up to 6 months. • May increase risk of stroke. • May increase risk of bleeding. • May affect blood glucose levels.
Ginseng (*Panax* species)	May improve mental performance May enhance immune system May lower blood glucose	• May increase or decrease blood pressure. • May increase risk of bleeding. • Avoid use in patients with hormone-sensitive conditions such as breast cancer.
Hawthorn	Mild to moderate heart failure	• May add to the effects of cardiac glycosides, antihypertensives, and cholesterol-lowering agents.
Kava	Anxiety	• FDA has issued warning of severe liver damage linked to use. • Avoid use in patients with liver problems and patients taking medications that affect liver. • May increase drowsiness. • Use cautiously with herbs or supplements that are metabolized by kidneys.
St. John's wort	Short-term treatment of depression (studies on benefits of use are contradictory)	• Well tolerated in recommended dosages for 1–3 months. • May lead to serious interactions with herbs, supplements, OTC drugs, or prescription drugs. • Interferes with metabolism of drugs that use cytochrome P450 enzyme system. • May lead to increased side effects when taken with other antidepressants. • Advise patients to consult health care professional before self-medicating with St. John's wort.
Zinc	Upper respiratory tract infections	• Relatively safe. • Should not be taken with dairy products or caffeine, which will reduce its absorption.

Source: Data from *www.naturalstandard.com*.
*Advise patients who are pregnant or lactating to consult a health care practitioner before using any herbs. There is limited scientific evidence for the use of most herbs during pregnancy or lactation.
FDA, Food and Drug Administration; *OTC,* over-the-counter.

Commonly used herbs are presented in Table 6-5. Although herbs are derived from plants, most individuals administer them in the form of a pill or capsule (Fig. 6-2). Commonly used dietary supplements are found in Table 6-6 on p. 84. Complementary and alternative therapy boxes related to specific herbs and dietary supplements are found throughout the book (see summary box on previous page).

Mind-Body Medicine

Mind-body medicine therapies focus on the interaction between the mind, the body, and behavior, with the intent to promote health. Examples of these therapies include meditation, yoga, relaxation breathing, guided imagery, and acupuncture. Because some of these therapies are used in stress management, they are discussed in Chapter 7.

FIG. 6-1 Yoga is an example of both mind-body medicine and manipulative and body-based practices. (Jupiterimages/Comstock/Thinkstock)

FIG. 6-2 Herbs are most commonly administered as a pill or capsule, but the source is a plant, such as echinacea. (iStockphoto/Thinkstock)

COMPLEMENTARY & ALTERNATIVE THERAPIES

Yoga

Yoga is an ancient system of relaxation, exercise, and healing with its origins in Indian philosophy. The goal of yoga is physical and mental well-being achieved through the use of stretching, postures, breathing practices, and meditation.

Scientific Evidence

There is evidence to support use of yoga to treat hypertension and to reduce stress and anxiety.*

Nursing Implications

- Regardless of the type of yoga, deep abdominal relaxation breathing is a main component and helps one to focus on the inner self and to promote the relaxation response (Fig. 6-1).
- Yoga is often used to promote relaxation, decrease stress, improve flexibility, and enhance overall health.
- Yoga is generally considered safe. Some postures should not be used by patients with certain medical conditions or illnesses.

*Based on a systematic review of scientific literature, available at *www.naturalstandard.com*.

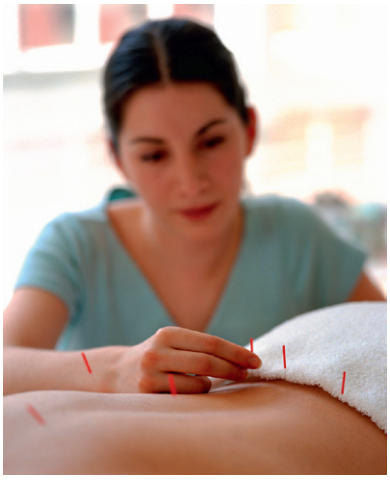

FIG. 6-3 Acupuncture showing the placement of acupuncture needles. (Creatas/Thinkstock)

Acupuncture. Acupuncture involves the insertion of fine needles into the circulation of Qi underneath the skin's surface (Fig. 6-3). Specific points are selected based on the diagnosis and nature of the complaint. With proper point selection and manipulation, acupuncture corrects disruptions in the flow of Qi.

Acupuncture has benefits for osteoarthritis, chronic pain, postoperative pain, headaches, fibromyalgia, postoperative nausea, and nausea and vomiting after chemotherapy.[7]

Acupuncture is considered a safe therapy when the practitioner has been appropriately trained and uses disposable needles. Patients should review their practitioner's credentials. The practitioner should have at least a master's degree in Oriental Medicine and be registered to practice acupuncture in that state. The practitioner should have passed the National Certification Commission for Acupuncture and Oriental Medicine examinations.

Manipulative and Body-Based Practices

Manipulative and body-based practices include interventions and approaches that are based on manipulation or movement of the body. Massage is one of the body-based methods commonly used by nurses.

Massage. Massage includes a range of techniques that manipulate the soft tissues and joints of the body. Involving touch and movement, massage is typically delivered with the hands, although elbows, forearms, feet, or various devices may be used. Massage techniques are used in bodywork, sports training, physical therapy, nursing, chiropractic therapy, osteopathy, and naturopathy.

Benefits of massage relate to its effects on the musculoskeletal, circulatory, lymphatic, and nervous systems. Massage also positively affects mental and emotional states. Massage therapy continues to grow in popularity, with most people using it as a means to reduce stress.

Until the 1970s, nurses were taught to perform "PM care," which consisted of a back rub and other measures to promote

TABLE 6-6 COMMONLY USED DIETARY SUPPLEMENTS*

Name	Uses Based on Scientific Evidence	Comments
Chondroitin sulfate	Osteoarthritis	• Well tolerated for up to 3 years. • Avoid in patients with prostate cancer or those at increased risk for prostate cancer. • Use with caution in patients with bleeding disorders or those taking anticoagulants.
Coenzyme Q_{10}	Hypertension	• May decrease blood glucose levels.
Fish oil/omega-3 fatty acids	Hypertriglyceridemia Hypertension	• May increase risk of bleeding. • May increase blood glucose levels.
Glucosamine	Osteoarthritis	• Use with caution in patients taking insulin or diabetes medications. • May increase risk of bleeding.
Melatonin	Jet lag Decrease sleep latency (time to fall asleep)	• May increase risk of bleeding. Use with caution in patients with bleeding disorders or those taking anticoagulant drugs. • May decrease blood pressure. • Use with caution in patients with diabetes. • Avoid in patients taking antiseizure medications or central nervous system depressants.
Probiotics (live bacteria or yeast)	Acute diarrhea related to antibiotic therapy Upper respiratory tract infections	• Use with caution in patients with compromised immune systems or gastrointestinal disorders.
Red yeast rice	High cholesterol and high triglycerides	• Some products contain monacolin K, which is the active ingredient in the cholesterol-lowering drug lovastatin.
Soy	High cholesterol	• Use with caution in patients with hormone-sensitive cancers. • May interact with medications taken for diabetes, diarrhea, hypertension, high cholesterol, obesity, or cardiovascular disorders. • Advise patients to consult a health care professional.

Data from *www.naturalstandard.com*.
*Advise patients who are pregnant or lactating to consult a health care professional before using any supplements. There is limited scientific evidence for use during pregnancy or lactation.

relaxation and sleep. After that time, PM care and back rubs became the exception rather than the rule. Yet today, with the increased focus on providing holistic care, nurses are again recognizing the benefits of massage. Massage is an important form of touch. It is also a form of caring, communication, and comfort. Your role related to massage differs from that of the registered massage therapist. Whereas massage therapists can provide more comprehensive therapies, nurses can use specific massage techniques as part of nursing care. For example, you can give a back massage to help promote sleep. For a bedridden patient, gentle massage can stimulate circulation and help prevent skin breakdown.

When you have determined that massage may be useful in meeting a patient goal, first assess the patient's preference regarding touch and massage. Consider cultural and social beliefs, and discuss potential benefits with the patient. Then you can implement the indicated plan of care (e.g., hand massage, back massage) with reassessment after the massage.

Massage Techniques. Nursing use of massage typically begins with *effleurage,* or gliding strokes, to promote relaxation. Stroking is done from distal to proximal, along the long axis of the muscle. After relaxing the muscles with effleurage, you may use *petrissage,* or a "kneading" stroke, to gently lift and knead the muscle. Gently scented lotions or diluted essential oils may be included in the massage.

A simple hand massage (Fig. 6-4) can have a calming and relaxing effect, especially for patients who are anxious or agitated. When a patient is frustrated or agitated, a hand massage can provide a distraction and calm the patient.

Family members can be taught to perform massage on their loved one, providing an excellent way for them to participate in patient care. This can be therapeutic for both the patient and the family, even when the loved one is cognitively impaired or unresponsive. Massage is beneficial throughout the life continuum. During end-of-life care, hospice nurses may incorporate massage into their nursing care, since the massaging touch can lessen pain and restlessness.

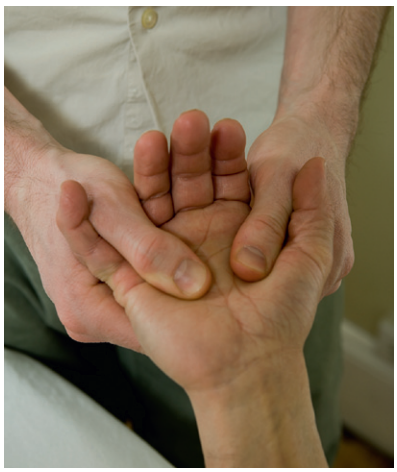

FIG. 6-4 Hand massage can be a helpful tool to calm down an agitated or nervous patient. (Jupiterimages/Photos.com/Thinkstock)

Massage is contraindicated in patients who have recent injuries or trauma, recent surgery, open wounds, deep vein thrombosis, inflammation or infections, bleeding, edema, or decreased sensation. Massage is also contraindicated when someone has used alcohol or recreational drugs.

Other CAT Practices

This broad category incorporates many practices, including movement therapies, practices of traditional healers, energy therapies, and whole body systems (see Table 6-3).

Energy Therapies. Energy therapies involve the manipulation of energy fields. They focus on energy fields originating within the body (biofields) or those from other sources (electromagnetic fields). Biofield therapies are based on the theory that energy systems in and around the body need to be balanced to enhance healing. Examples of energy therapies include Healing Touch, Therapeutic Touch, and Reiki.

Healing Touch (HT) is a nurse-based program founded in the 1980s by a nurse, Janet Mentgen. In HT, the nurse gently places his or her hands on or near the patient's clothed body. Based on established guidelines, the nurse assesses the patient's energy field, realigns energy flow, eliminates energy blockages, reactivates the mind-body-spirit connection, and then evaluates the process. It is an organized system designed to assist the patient to self-heal. The patient, not the nurse, determines effectiveness.

Information on classes, resources, and research findings is available at the Healing Touch International website *(www.healingtouchinternational.org)*.

GERONTOLOGIC CONSIDERATIONS

COMPLEMENTARY AND ALTERNATIVE THERAPIES

Older adults with non–life-threatening, chronic conditions are likely to use complementary and alternative therapies. For the older adult, safety concerns involve herb-drug interactions or toxicity related to polypharmacy and age-related changes in pharmacokinetics. Decreased renal or liver function may slow metabolism and excretion of herbs and dietary supplements. Since older adults are a more vulnerable population, it is critical that you discuss the risks and benefits of using herbal products, while encouraging patients to inform their health care provider of any herbal product or dietary supplement they are taking.

NURSING MANAGEMENT COMPLEMENTARY AND ALTERNATIVE THERAPIES

The professional nurse can use complementary and alternative therapies in professional practice and also in self-care practice.

PROFESSIONAL PRACTICE

In professional practice, be knowledgeable of these therapies, assess their use in patients, and promote their safety. You can incorporate many of these therapies into your professional nursing practice.

KNOWLEDGE OF THERAPIES. The use of complementary and alternative therapies continues to grow, and your patients expect you to know about them. Nursing schools are incorporating content relating to complementary and alternative therapies into their curriculum. Questions related to this topic are on the National Council Licensure Examination (NCLEX).

It is important for you to understand the commonly used CAT. This includes their clinical uses and scientific-based evidence for their uses. In addition, you need to know about the personal, cultural, and spiritual dimensions related to these therapies. As a nurse, you have been educated as a critical thinker and problem solver. You need to seek ongoing education regarding complementary and alternative therapies and to continually evaluate the evidence for use of these therapies.

You need to provide information on both conventional therapies and complementary and alternative therapies. Advise patients that complementary and alternative therapies do not replace conventional therapies, but can often be used in combination with them. By providing this information, you help patients make informed decisions. You are well positioned to become the "link" between conventional therapy and complementary and alternative therapies.

ASSESSMENT OF COMPLEMENTARY AND ALTERNATIVE THERAPY USE. Because many patients use these therapies, you need to collect data on the use of complementary and alternative therapies as part of your nursing assessment. This is important because most patients do not voluntarily tell their health care provider about their use of these therapies. However, they usually share this information when asked. Ask general, open-ended questions, while remaining nonjudgmental and respectful of the patient's response.

Examples of assessment questions include the following:

- Do you have any conditions that have not responded to conventional medicine? If so, have you tried any other approaches?
- Are you using any vitamin, mineral, dietary, or herbal supplements?
- Are you interested in obtaining information about complementary and alternative therapies?

Additional specific questions for assessing the use of herbs and dietary supplements are presented in the Complementary & Alternative Therapies box in Chapter 3 on p. 44.

PROMOTING SAFE USE OF THERAPIES. The American Nurses Association Code of Ethics states: "The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient." A wide variety of therapies are considered complementary and alternative, and some of these therapies may be ineffective or even harmful. However, patients self-select use of these therapies, generally without consulting a health care professional. Safety concerns encompass the reliability of information, the safety and effectiveness of therapies, and the regulation of practitioners. Patients usually get their information from health food stores, friends, books, magazines, and the Internet. Encourage patients to seek professional assistance with these decisions.

There is a lack of regulation of providers of complementary and alternative therapies. For example, in most states massage therapists and acupuncturists are licensed by the state. However, this practice varies by state. Practitioners of some other therapies are more loosely regulated. Along with the challenge of obtaining accurate information, patients may be unable to assess the competency of practitioners. You can serve as a resource to guide patients in the safe use of therapies and in the safe choice of health care practitioners.

INCORPORATING THERAPIES IN PRACTICE. Nursing has a long history of providing therapies that have been considered complementary and alternative. These include massage, relaxation therapy, music therapy, humor, and other strategies to promote comfort, reduce stress, improve coping, and promote symptom relief (Table 6-7). Although these therapies are generally included within the scope of nursing practice, they are not specifically addressed in some state board of nursing practice acts.

TABLE 6-7 NURSES CAN USE COMPLEMENTARY AND ALTERNATIVE THERAPIES

If you have the training and experience, you can use the following:

- Acupressure
- Animal-assisted therapy
- Aromatherapy
- Healing Touch
- Humor
- Imagery
- Journaling
- Massage
- Meditation
- Music
- Prayer
- Reiki
- Relaxation breathing
- Therapeutic Touch

Some of these therapies require additional education, training, or supervision. Check with the board of nursing in your state to determine what therapies fall within the nursing domain. You are expected to obtain the necessary additional education and experience to be competent to use a selected therapy. In addition, institutional or workplace policies must be in place supporting the use of these therapies.

You are responsible for ensuring that the patient has given consent for a given therapy. The patient must be aware of the proposed benefit and any potential risks involved. Document the effectiveness of the intervention and evaluate the outcome.

SELF-CARE PRACTICE

Learning about complementary and alternative therapies can be one road to self-care. Initially, you may be eager to learn about complementary and alternative therapies so you can provide better patient care and be a holistic practitioner. At the same time, you may find that these therapies can enhance your own level of health and wellness. With the many different complementary and alternative therapies available, you should be able to find some that will promote your personal well-being. Examples of therapies that nurses commonly use for personal well-being include deep-breathing exercises, meditation, prayer, yoga, aromatherapy, massage, and music. It is essential that you, as the caregiver, first care for yourself before you can help the patients who need your care.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. One characteristic of the integrative model of health care is
   a. increased cost.
   b. a focus on physical disease states.
   c. an integration of mind-body-spirit.
   d. the plan of care is directed by the health care provider.
2. The nurse is preparing to teach a patient about stress management. Which category of complementary and alternative therapies can guide the nurse in preparing this intervention?
   a. Natural products
   b. Energy therapies
   c. Mind-body medicine
   d. Manipulative and body-based practices
3. The nurse is teaching a patient about safe use of herbal therapies. Which statement indicates that the teaching has been effective?
   a. "I can increase the dose if I need to, since these pills are natural."
   b. "I don't have to tell my physician about this herb that I am taking."
   c. "I must remember to stop taking these herbs 2 to 3 weeks before I have surgery."
   d. "I can stop taking my blood pressure medication now that I am taking these herbs."
4. Which herbs can increase a patient's risk of bleeding *(select all that apply)*?
   a. Aloe
   b. Kava
   c. Garlic
   d. Ginger
   e. Feverfew
5. The nurse decides to incorporate complementary and alternative therapies into her practice. Which is the best source of information?
   a. Internet websites
   b. Board of nursing for her state
   c. Salesperson at the health food store
   d. Another nurse who claims his practice is holistic
6. The nurse is preparing to collect data on an older patient's use of complementary and alternative therapies. Which guidelines should the nurse follow?
   a. The patient's culture will probably dictate which therapies are used.
   b. Begin by asking general questions, and then move to more specific questions.
   c. Obtain this information from the medical record. It is not necessary to ask the patient.
   d. Older patients do not use complementary and alternative therapies because of age-related changes in pharmacokinetics.
7. The nurse is experiencing work-related stress and desires to develop a holistic plan of self-care. What is the best source of reliable information?
   a. A self-help book
   b. Internet websites
   c. Another nurse who does not seem stressed
   d. Professional nursing organizations such as AHNA

1. c, 2. c, 3. c, 4. c, d, e, 5. b, 6. b, 7. d.

LEARNING OUTCOMES

1. Differentiate between the terms *stressor* and *stress*.
2. Explain the role of coping in managing stress.
3. Describe the role of the nervous and endocrine systems in the stress process.
4. Describe the effects of stress on the immune system.
5. Discuss the effects of stress on health.
6. Describe the coping and relaxation strategies that can be used by you or a patient experiencing stress.
7. Describe the nursing assessment and management of a patient experiencing stress.

KEY TERMS

coping, p. 92
emotion-focused coping, p. 92
imagery, p. 94
meditation, p. 94
problem-focused coping, p. 92
psychoneuroimmunology (PNI), p. 91
relaxation breathing, p. 93
stress, p. 88
stressors, p. 88

High levels of stress and anxiety are common among patients and their caregivers. How they deal with their stress is critical to their well-being. As a nurse, you have an important role in helping them manage stressful events.

Stress has a powerful effect on the mind, and therefore a significant effect on one's health and well-being. This chapter focuses on how stress can affect the mind and the body and how a person can effectively deal with stress.

DEFINITION OF STRESS

Stress is the inability to cope with perceived (real or imagined) demands or threats to one's mental, emotional, or spiritual well-being.[1] Because demands are perceived differently based on the person and situation, what is emotionally or psychologically stressful to one person may not be stressful to another. Individual responses to the same stressor vary greatly. *Perception* of the potential stressor influences the way an individual responds to that stressor (Fig. 7-1). This is demonstrated in the following examples.

- B.J., a 43-year-old woman, becomes depressed after a laparoscopic hysterectomy for fibroids. She is unwilling to participate in normal self-care activities. You are surprised by her response and think that this is fairly simple surgery and she should get on with her life. After further assessment, you discover that the removal of her uterus is a great psychologic stressor because she perceives it as a loss of her womanhood and femininity.
- K.R., a 52-year-old woman, has just been told by her physician of her new diagnosis of type 2 diabetes. After the physician's visit to her, you are prepared to provide emotional support. However, you are puzzled when she is smiling and breathing a sigh of relief. You think that this diagnosis should be stressful. However, K.R. tells you that she is so relieved because for weeks she has worried that her symptoms were related to terminal cancer.

Many different events or factors can be **stressors.** They can be physiologic or emotional/psychologic (see Fig. 7-1). The emotional/psychologic stressors can be positive or negative. For example, the birth of a baby is a positive stressor. Marital discord is a negative stressor.

The key aspect of stressors is that they require an individual to adapt. In addition, differences in the behavioral and physiologic adaptive responses to a stressor can be based on the duration of a stressor (acute or chronic) and intensity of a stressor (mild, moderate, or severe). For example, an

Reviewed by Margie Hesson, RN, MSN, Certified Holistic Stress Management Instructor, Instructor of Nursing, South Dakota State University, Rapid City, South Dakota.

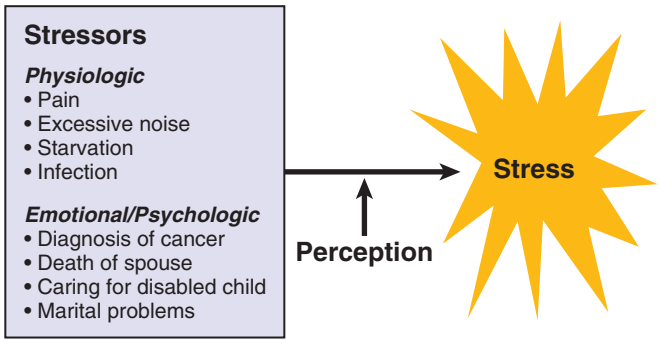

FIG. 7-1 Stressors can be physiologic or emotional/psychologic. Your perception of these stressors will determine whether they cause stress. Events or circumstances become stressful when you perceive them to be.

FIG. 7-2 During stressful situations, the demands seem to exceed the resources. (iStockphoto/Thinkstock)

individual dealing with the chronic stress of caring for a loved one may also be exposed to many acute episodic stressors (e.g., car accident, influenza). Therefore the type, duration, and intensity of a stressor are important variables that can influence an individual's adaptive response (Fig. 7-2).

FACTORS AFFECTING RESPONSE TO STRESS

Why do people respond so differently to stress? Why do some people cope better with stress than others? Interestingly, some individuals experience significant adverse life events but do not succumb to the effects of stress. Factors that affect an individual's response to stress include internal and external influences (Table 7-1). These factors indicate the importance of using a holistic approach when assessing the impact of stress on a person.

Four key personal characteristics that buffer the effects of stress are resilience, hardiness, attitude, and optimism. *Resilience* is being resourceful and flexible and having good problem-solving skills. Individuals who possess a high degree of resilience are not as likely to perceive an event as stressful or taxing.

Hardiness is a combination of three characteristics: commitment, control, and openness to change. Together they provide the courage and motivation needed to turn stressful circumstances from potential calamities into opportunities for personal growth.[2]

Attitude can also influence the effect of stress on a person. People with positive attitudes view situations differently from those with negative attitudes. A person's attitude also influences how he or she manages stress. To some extent, positive emotional attitudes can prevent disease and prolong life.[3]

TABLE 7-1 FACTORS AFFECTING PERSON'S RESPONSE TO STRESS

Internal	External
• Age • Health status • Personality characteristics • Previous experience with stressors • Genetic background • Resilience • Hardiness • Attitude • Optimistic outlook • Nutritional status • Sleep status	• Cultural and ethnic influences • Socioeconomic status • Social support • Religious or spiritual influences • Timing of stressors • Number of stressors already experiencing

PATHOPHYSIOLOGY MAP

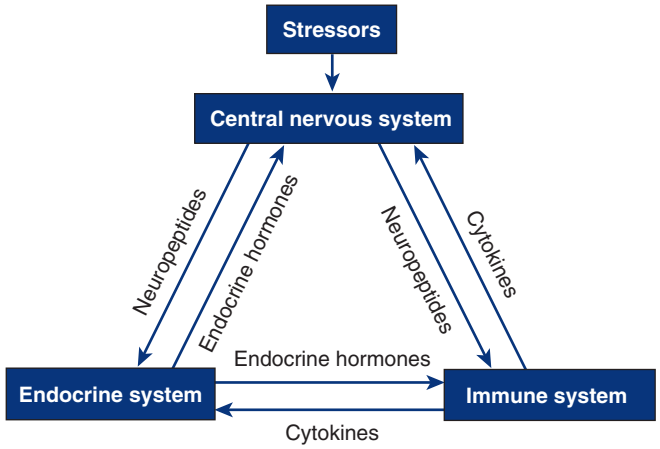

FIG. 7-3 Neurochemical links among the nervous, endocrine, and immune systems. The communication among these three systems is bidirectional.

Optimists are able to cope more effectively with stress. Optimism also reduces a person's chances of developing stress-related illnesses. When optimistic people do become ill, they tend to recover more quickly. Pessimists are likely to deny the problem, distance themselves from the stressful event, focus on stressful feelings, or allow the stressor to interfere with achieving a goal. People with a more pessimistic attitude tend to report poorer health than people with optimistic attitudes.[3]

In addition to personal characteristics, external factors play an important role in one's ability to cope with stress. Being surrounded by a strong social support system and receiving positive support from friends and family have a large impact on an individual's ability to cope with stressors.

PHYSIOLOGIC RESPONSE TO STRESS

The following section discusses the roles of the nervous, endocrine, and immune systems. These systems are interrelated, and that interrelationship is reflected in a person's physiologic response to stress (Fig. 7-3). Further, stress activation of these systems affects other body systems, such as the cardiovascular, respiratory, gastrointestinal, renal, and reproductive systems.

The complex process by which an event is perceived as a stressor and the body responds is not fully understood. A person's response to a stressor (real or imagined, and physiologic

or emotional/psychologic) determines the impact that stress will have on the body.[4]

Hans Selye, a pioneer in stress research more than 70 years ago, showed that stressors from different sources produced a similar physical response. He termed this physical response to stress the *general adaptation syndrome* (GAS), which has three stages: alarm reaction, stage of resistance, and stage of exhaustion.[5] The GAS is presented in eTable 7-1 on the website for this chapter.

Nervous System

Cerebral Cortex. The cerebral cortex evaluates the emotional/psychologic event (stressor) in light of past experiences and future consequences, and thus plans a course of action. These functions are involved in the perception of a stressor.

Limbic System. The *limbic system* lies in the inner midportion of the brain near the base of the brain. The limbic system is an important mediator of emotions and behavior. When the limbic system is stimulated, emotions, feelings, and behaviors can occur that ensure survival and self-preservation.

Reticular Formation. The *reticular formation* is located between the lower end of the brainstem and the thalamus. It contains the *reticular activating system* (RAS), which sends impulses contributing to alertness to the limbic system and to the cerebral cortex. When the RAS is stimulated, it increases its output of impulses, leading to wakefulness. Stress usually increases the degree of wakefulness and can lead to sleep disturbances.

Hypothalamus. The hypothalamus, which lies at the base of the brain just above the pituitary gland, has many functions that assist in adaptation to stress. Stress activates the limbic system, which in turn stimulates the hypothalamus. Because the hypothalamus secretes neuropeptides that regulate the release of hormones by the anterior pituitary, it is central to the connection between the nervous and endocrine systems in responding to stress (Fig. 7-4).

The hypothalamus plays a primary role in the stress response by regulating the function of both the sympathetic and parasympathetic branches of the autonomic nervous system. When an individual perceives a stressor, the hypothalamus sends signals that initiate both the nervous and endocrine responses to the stressor. It does this primarily by sending signals via nerve fibers to stimulate the sympathetic nervous system (SNS) and by releasing corticotropin-releasing hormone (CRH), which stimulates the pituitary to release adrenocorticotropic hormone (ACTH) (see Chapter 48).

Endocrine System

Once the hypothalamus is activated in response to stress, the endocrine system becomes involved. The SNS stimulates the adrenal medulla to release epinephrine and norepinephrine (catecholamines). The effect of catecholamines and the SNS, including the response of the adrenal medulla, is referred to as the *sympathoadrenal response.* Epinephrine and norepinephrine prepare the body for the *fight-or-flight response* (Fig. 7-5).

Stress activates the hypothalamic-pituitary-adrenal (HPA) axis. In response to stress, the hypothalamus releases CRH, which stimulates the anterior pituitary to release proopiomelanocortin (POMC). Both ACTH (a hormone) and β-endorphin (a neuropeptide) are derived from POMC. Endorphins have analgesic-like effects and blunt pain perception during stress situations involving pain stimuli. ACTH, in turn, stimulates the adrenal cortex to synthesize and secrete corticosteroids (e.g., cortisol) and, to a lesser degree, aldosterone.

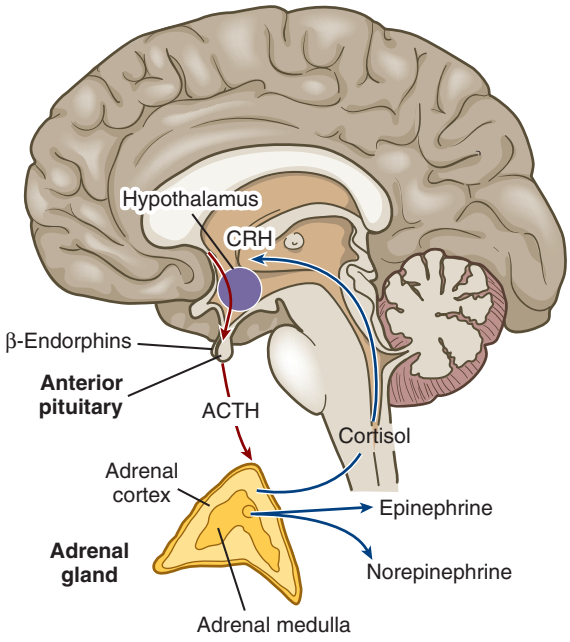

FIG. 7-4 Hypothalamic-pituitary-adrenal axis. *ACTH,* Adrenocorticotropic hormone; *CRH,* corticotropin-releasing hormone.

Corticosteroids are essential for the stress response. Cortisol produces a number of physiologic effects, such as increasing blood glucose levels, potentiating the action of catecholamines on blood vessels, and inhibiting the inflammatory response. Corticosteroids play an important role in "turning off" or blunting aspects of the stress response, which if uncontrolled can become self-destructive. This is exemplified by corticosteroids' ability to suppress the release of proinflammatory mediators, such as the cytokines tumor necrosis factor (TNF) and interleukin-1 (IL-1). The persistent release of such mediators is believed to initiate organ dysfunction in conditions such as sepsis. Thus corticosteroids act not only to support the body's adaptive response to a stressor, but also to suppress an overzealous and potentially self-destructive response.

The stress response involves increases in (1) cardiac output (resulting from the increased heart rate and increased stroke volume), (2) blood glucose levels, (3) oxygen consumption, and (4) metabolic rate (see Fig. 7-5). In addition, dilation of skeletal muscle blood vessels increases blood supply to the large muscles and provides for quick movement. Increased cerebral blood flow increases mental alertness. The increased blood volume (from increased extracellular fluid and the shunting of blood away from the gastrointestinal system) helps maintain adequate circulation to vital organs in case of traumatic blood loss.

Summary of Stress Response

In summary, the fight-or-flight response is an important adaptive mechanism of the body to acute stress. This response to stressors is activated regardless of whether they are physiologic (e.g., acute pain) or emotional/psychologic (e.g., death of a child, loss of a home through fire, fear).

The acute stress response is a state of physiologic and psychologic arousal characterized by increased SNS activity that leads to increased heart and respiratory rate, increased blood

PATHOPHYSIOLOGY MAP

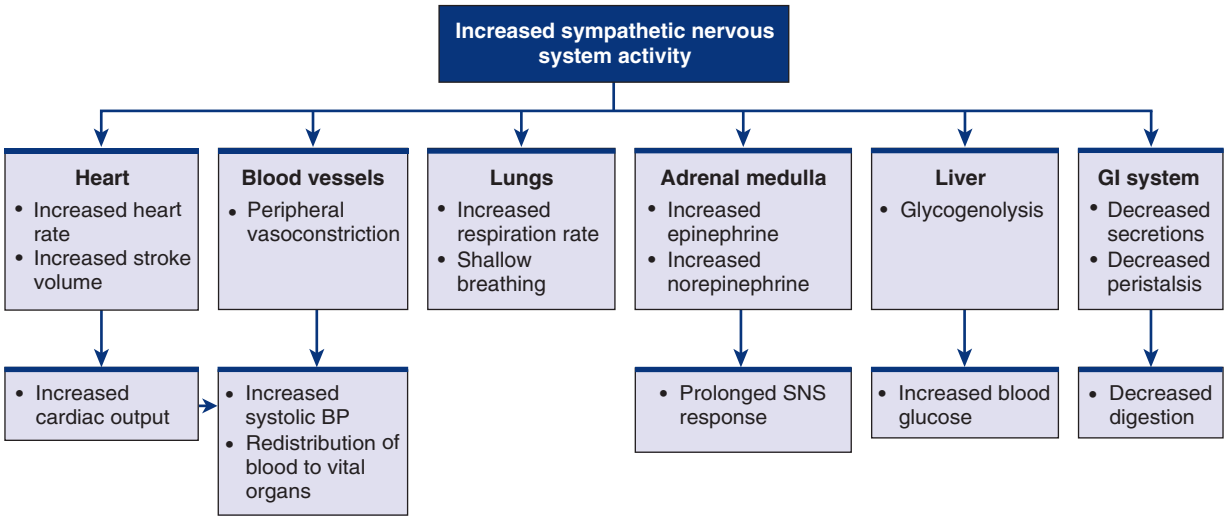

FIG. 7-5 "Fight-or-flight" reaction. Alarm reaction responses resulting from increased sympathetic nervous system *(SNS)* activity.

pressure, increased muscle tension, increased brain activity, and decreased skin temperature.

Immune System

Stress also has an impact on the immune system. **Psychoneuroimmunology (PNI)** is an interdisciplinary science that studies the interactions among psychologic, neurologic, and immune responses.[6] Because the brain is connected to the immune system by neuroanatomic and neuroendocrine pathways, stressors have the potential to lead to alterations in immune function (Fig. 7-6).

Nerve fibers extend from the nervous system and synapse on cells and tissues of the immune system (i.e., spleen, lymph nodes). In turn, the cells of the immune system have receptors for many neuropeptides and hormones, which permit them to respond to nervous and neuroendocrine signals. As a result, the mediation of stress by the central nervous system leads to corresponding changes in immune cell activity.

Both acute and chronic stress can cause immunosuppression. Stress affects immune function by (1) decreasing the number and function of natural killer cells; (2) decreasing lymphocyte proliferation; (3) altering production of *cytokines* (soluble factors secreted by white blood cells and other cells), such as interferon and interleukins; and (4) decreasing phagocytosis by neutrophils and monocytes.[7] (Natural killer cells, lymphocytes, and cytokines are discussed in Chapter 14.)

Importantly, the network that links the brain and immune system is bidirectional (see Fig. 7-3). Signals from these systems travel back and forth, allowing for communication among these systems. Consequently, not only do emotions modify the immune response, but products of immune cells send signals back to the brain and alter its activity. Many of the communication signals sent from the immune system to the brain are mediated by cytokines, which are central to the coordination of the immune response. For example, IL-1 (a cytokine made by monocytes) acts on the temperature regulatory center of the hypothalamus and initiates the febrile response to infectious pathogens (see Fig. 12-3).

PATHOPHYSIOLOGY MAP

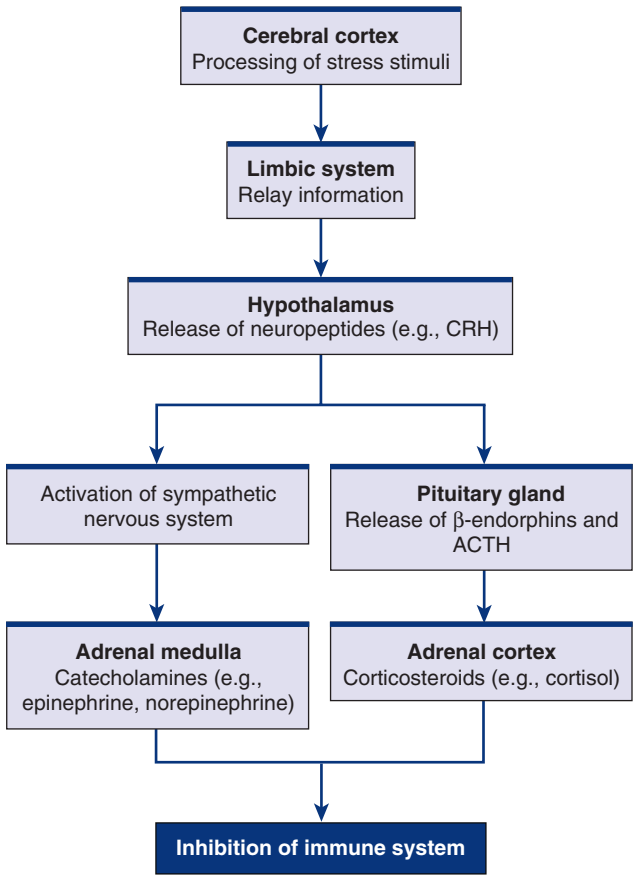

FIG. 7-6 The cerebral cortex processes stressful stimuli and relays the information via the limbic system to the hypothalamus. Corticotropin-releasing hormone *(CRH)* stimulates the release of adrenocorticotropic hormone *(ACTH)* from the pituitary gland. ACTH stimulates the adrenal cortex to release corticosteroids. The sympathetic nervous system is also stimulated, resulting in the release of epinephrine and norepinephrine from the adrenal medulla. The end result is the inhibition of the immune system.

The central nervous system is capable of influencing the function of the immune system. Stress-induced immunosuppression may exacerbate or increase the risk of progression of immune-based diseases such as multiple sclerosis, asthma, rheumatoid arthritis, and cancer.[7-9]

Many questions about stress and the immune response remain unanswered. For example, it is not known how much stress is needed to cause changes or how much of an alteration in the immune system is necessary before disease susceptibility occurs. A current challenge for researchers in the field of PNI is to study stress-induced immune changes and their relationship to health and to illness outcomes.

EFFECTS OF STRESS ON HEALTH

Acute stress leads to physiologic changes that are important to a person's adaptive survival. This is your "alarm system." It puts you on high alert. However, if stress is excessive or prolonged, these same physiologic responses can be maladaptive and lead to harm and disease. Your body was not meant to be on high alert all of the time. When a person sustains chronic, unrelieved stress, the body's defenses can no longer keep up with the demands. Therefore stress plays a role in the development or progression in the diseases of adaptation, or stress-related illnesses (Table 7-2).

Stress is linked to leading causes of death, including cancer, accidents, and suicides. Stress can have effects on cognitive function, including poor concentration, memory problems, distressing dreams, sleep disturbances, and impaired decision making. Stress can also cause a wide variety of changes in behavior. These include people withdrawing from others, becoming quiet or unusually talkative, changing eating habits, drinking alcohol excessively, or becoming irritable.[4,8-10]

Long-term exposure to catecholamines resulting from excessive activation of the SNS may increase the risk of cardiovascular diseases such as atherosclerosis and hypertension. Other conditions that are either precipitated or aggravated by stress include migraine headaches, irritable bowel syndrome, and peptic ulcers.[9,10] Control of metabolic conditions, such as diabetes mellitus, is also affected by stress. Behavioral interventions aimed at stress reduction and relaxation have been successful in helping to manage these diseases in conjunction with standard medical therapy.

Stressful life events can make a person more susceptible to infection. For example, psychologic stress may increase one's risk for developing the common cold. In a landmark study, healthy volunteers were inoculated intranasally with low doses of upper respiratory tract viruses. The subjects underwent psychologic testing to determine the occurrence of stressful events in their lives and their reactions to such stresses. The results showed that the rates of both viral infection and clinical colds increased with the degree of psychologic stress. In this study, social support buffered the harmful effects of stress.[11]

Obesity and depression are often exacerbated by stress. Those who suffer from these conditions report that they are unable to take the necessary steps to relieve their stress or improve their health and therefore engage in maladaptive coping behaviors.[12]

At the cellular level, stress may promote earlier onset of age-related diseases. There is a link between stress and telomere length. Telomeres are the protective end caps on chromosomes, and their diminishing size is an indication of age. Telomeres are highly susceptible to stress and depression. Telomeres are shorter in people who are stressed and depressed than in healthy people. Thus chronic stress can have a long-term effect on our overall health by changing our DNA and accelerating the rate at which our cells age.[13,14]

Adverse experiences early in life have an impact on brain functions. Early life stress can program the development of the hypothalamic-pituitary-adrenal axis and eventually result in neurobehavioral changes.[15] People exposed to major psychologic stressors in early life have elevated rates of morbidity and mortality from chronic diseases of aging. Children raised in poverty or mistreated by their parents have increased risk for vascular disease, autoimmune disorders, and premature death.[16]

Chronic stress is a major driver of chronic illness, which in turn is a major driver of escalating health care costs. It is critical that the entire health care community recognize the role of stress and unhealthy behaviors in causing and exacerbating chronic health conditions.[12]

*List is not all inclusive.

COPING

Coping is a person's cognitive and behavioral efforts to manage stressors that seem to exceed available resources.[17] Coping can be either positive or negative. Positive coping includes activities such as exercise and spending time with friends and family. Negative coping may include substance abuse and denial.

The availability of coping resources affects an individual's ability to cope with stressful situations. *Coping resources* are characteristics or behaviors drawn on to manage stress. They include factors within the person or the environment, such as health status, belief systems, problem-solving skills, social skills, social support, and financial resources. Knowledge of a patient's coping resources can assist you in supporting existing resources and developing strategies to expand the patient's coping resources.

Coping strategies can be divided into two broad categories: emotion-focused coping and problem-focused coping. **Emotion-focused coping** involves managing the emotions that an individual feels when a stressful event occurs. Examples of emotion-focused coping include discussing feelings with a friend or taking a hot bath. **Problem-focused coping** involves attempts to resolve the problems causing the stress. Setting priorities or collecting information and seeking advice are examples of problem-focused coping.

Both strategies can be used to cope with stressors, and a combination of these strategies can be used to cope with the same stressor. Table 7-3 provides examples of emotion- and problem-focused coping when applied to the same stressful situation. Table 7-4 contains examples of coping strategies.

> *You cannot always choose your destiny in life, but you can choose how you cope with it.*
> *Norman Vincent Peale*

TABLE 7-3 PROBLEM- AND EMOTION-FOCUSED COPING

Stressor	Problem-Focused Coping	Emotion-Focused Coping
Failing an examination	Obtaining a tutor	Going for a run
Being diagnosed with diabetes	Attending diabetic education classes	Getting a massage
Receiving questionable mammogram results	Scheduling follow-up testing for ultrasound	Expressing feelings of anxiety to friends and nurse

TABLE 7-4 COPING STRATEGIES

Strategy	Description
Social support	• Self-help groups and professional help • Relationships with family and friends
Exercise	• Any form of movement, especially aerobic movement • Can be viewed as meditation in motion • Results in improved circulation, increased release of endorphins, and an enhanced sense of well-being
Journaling	• Allows an individual to express self in writing • Can write about personal events, thoughts, feelings, memories, and perceptions • Allows an individual to reduce stress, enhance coping, and increase self-awareness
Art therapy	• Allows an individual to nonverbally express and communicate feelings, emotions, and thoughts • Can reduce stress, promote relaxation, and help process experiences • Based on the belief that creative process is healing and life enhancing
Humor	• Can take the form of laughter, cartoons, funny movies, videos, riddles, comic books, and joke books • Humor carts set up in many clinical settings to be used by patients and families

When a situation is unchangeable or uncontrollable, emotion-focused coping may predominate. The primary purpose of emotion-focused coping is to help decrease negative emotions and create a feeling of well-being. Although it may not seem to be working toward a solution, emotion-focused coping is a valid and appropriate way to deal with different stressful situations.

If a problem can be changed or controlled, problem-focused coping is the most helpful coping strategy. Problem-focused coping strategies allow an individual to look at a challenge objectively, take action to address the problem, and thereby reduce the stress.

A key aspect of successful coping is *coping flexibility*, which involves the ability to change and adapt coping strategies over time and across different stressful conditions. Stressful circumstances are handled best when an individual uses coping flexibility because certain strategies work more effectively than others depending on the circumstances.

RELAXATION STRATEGIES

The *relaxation response* is a state of physiologic and psychologic rest. It is the opposite of the stress response. The relaxation response is characterized by decreased SNS activity, which leads to decreased heart and respiratory rate, decreased blood pressure, decreased muscle tension, decreased brain activity, and increased skin temperature.[18]

TABLE 7-5 RELAXATION BREATHING TECHNIQUES*

Breathing Assessment

- Begin by placing one hand gently on your abdomen below your waistline.
- Place the other hand on the center of your chest on the sternum.
- Without changing the normal breathing pattern, take several breaths. During inhalation notice which hand rises the most.
- When relaxation breathing is performed properly, the hand on the abdomen should rise more than the hand on the chest.

4 × 4 Technique

- Sit up straight with your back flush to the support of the chair and your feet flat on the floor.
- Rest your arms on your lap, thighs, or arms of the chair.
- Take in a deep breath through your nose to a count of four (1 … 2 … 3 … 4).
- Hold your breath to a count of four (1 … 2 … 3 … 4).
- Release your breath through your mouth to a count of four (1 … 2 … 3 … 4).
- Rest for a count of four (1 … 2 … 3 … 4).
- Repeat the cycle four times.

*Evolve Video demonstrations of these techniques are available in the Stress-Busting Kit for Nursing Students on the website for this book.

The relaxation response can be elicited through a variety of relaxation strategies, including relaxation breathing, meditation, imagery, muscle relaxation, prayer, and physical exercise. The most common relaxation strategies are described here. Regular elicitation of the relaxation response has been proven to be an effective treatment for a wide range of stress-related disorders, including chronic pain, insomnia, and hypertension. Individuals who regularly engage in relaxation strategies are able to deal better with their stressors, increase their sense of control over stressors, and reduce their tension.[19]

Relaxation Breathing

The way one breathes affects every aspect of one's life. When a person is stressed, muscles tense and breathing becomes shallow and rapid. Therefore one of the simplest and most effective ways to stop the stress response is to breathe deeply and slowly. It is difficult to maintain tension when breathing in a slow, deep, and relaxed pattern.

Relaxation (abdominal) **breathing** can be performed while sitting, standing, or lying down. It is especially useful during a stressful or anxious situation to reduce stress. Relaxation breathing forms the basis for most relaxation strategies.

Before practicing relaxation breathing, it is important to assess one's normal breathing pattern (Table 7-5). Chest breathing, which involves the upper chest and shoulders, is inefficient. This type of breathing is often used during times of anxiety and distress. Relaxation breathing, which involves the diaphragm, is natural for newborns and sleeping adults. It is a more efficient type of breathing.

Relaxation breathing involves the primary use of the diaphragm and less use of the upper chest and shoulders to assist in each breath. In this type of breathing, the abdomen gently moves in and out during exhalation and inhalation. The breaths should be slow, steady, and deep.

One basic technique for relaxation breathing is as follows: (1) Inhale slowly and deeply, pushing the abdomen out, thinking about breathing in peace. (2) Exhale slowly, letting the abdomen come in and all the muscles relax. (3) Repeat these deep breaths 10 times without interruption. As with any breath-

ing exercise, if a light-headed feeling arises, stop for 30 seconds and then start again.

A common method used to teach relaxation breathing is the 4 × 4 technique (see Table 7-5). Other breathing techniques are discussed in the Stress-Busting Kit for Nursing Students available on the website for this book.

Initially, relaxation breathing may feel unusual. With practice it becomes easier, and its relaxing benefits are soon obvious. You should personally learn to use relaxation breathing before teaching it to patients. Once learned, relaxation breathing can be easily taught to patients in a variety of settings, particularly when they are undergoing stressful and painful procedures.

Meditation

Meditation is a state of being with increased concentration and awareness. Meditation can be used to create a sustained period during which one focuses attention and increases self-awareness. Many seek out meditation in response to a deep human need for something transcendental or beyond everyday experiences. However, meditation can also be used to reduce stress.

Three basic ways to practice meditation are (1) concentration methods, (2) guided meditation, and (3) mindfulness practices. The *concentration technique* (e.g., Zen meditation) directs the mind to a single focus, such as the breath, an object, or a *mantra.* A *guided meditation* is similar to guided imagery (described below), where the mind and imagination are focused on a conscious goal. *Mindfulness practices* (e.g., transcendental meditation) are not restricted to any one object but rather attend to any and all sensations, perceptions, thoughts, and emotions as they arise moment to moment in the field of awareness.

Although meditation can be performed anywhere, it is best to practice meditation in a quiet place, free of distractions. Table 7-6 provides some basic guidelines on how to meditate. Meditation is often practiced while seated, and it is important to maintain a comfortable posture. Meditation can also be performed while walking and focusing on a single action such as the movement of the feet. In the beginning, individuals typically start with just 5 to 10 minutes of meditation at a time and often increase the time as the practice becomes more comfortable.

In people who meditate regularly, the brain is reoriented from a stressful fight-or-flight mode to one of acceptance, a shift that increases contentment.[20] Similarly, long-term meditation practices create structural differences in the lower brainstem, which could account for some of the cardiovascular and respiratory parasympathetic effects, as well as cognitive, emotional, and immunoreactive changes. Meditation has many positive health benefits, including reversal of coronary artery disease, decreased levels of cortisol, decreased cholesterol levels, increased airflow to the lungs, and increased immune functions.[21]

TABLE 7-6 GUIDE TO MEDICATION*

You can teach yourself the basics of meditation by following a few simple steps:

- Find a quiet place.
- Make sure there are no distractions.
- Sit in a comfortable position.
- Close your eyes.
- Shut out the world so your brain can stop processing information coming from your senses.
- Pick a word or phrase. Find a word or phrase that means something to you, whose sound or rhythm is soothing when repeated (e.g., one, peace, shalom, the Lord is my shepherd, Hail Mary full of grace).
- Breathe slowly and practice relaxation breathing.
- Say the word or phrase again and again.
- Try saying the word or phrase silently to yourself with every exhalation. The monotony will help you focus.
- Do not be concerned when other thoughts come to mind. Just acknowledge them and return calmly to your word or phrase.
- Continue for 10 to 20 minutes, but even 5 minutes can leave you feeling calm and refreshed.
- Rise slowly.

Practice once or twice daily.

*Evolve Meditation exercises are available in the Stress-Busting Kit for Nursing Students on the website for this book.

Imagery

Imagery is the use of one's mind to generate images that have a calming effect on the body. It involves focusing the mind and incorporates all the senses to create physiologic and emotional changes. It is a simple relaxation technique that requires no equipment other than an active imagination. *Guided imagery* is a variation of imagery in which images are suggested by another person (either live or on a CD or MP3 file).

Imagery can be used in many clinical settings for stress reduction and pain relief. Benefits of imagery include anxiety reduction, decreased muscle tension, improved comfort during medical procedures, enhanced immune function, decreased recovery time after surgery, and reduction in sleeping problems. You can use imagery in your own life or use guided imagery with your patients. One of the uses of imagery is to create a safe and special place for mental retreat to elicit the relaxation response. Table 7-7 describes the steps involved in creating a special place.

When imagery is performed, it is best to find a comfortable position. Take slow, deep breaths. Focus should involve all senses (sight, hearing, touch, smell). For example, one can use an image such as Fig. 7-7, engaging all the senses as one focuses on the image.

Imagery can also be used to specifically target a disease, problem, or stressor. Table 7-8 describes some suggestions for using imagery in specific diseases or disorders.

TABLE 7-7 IMAGERY: CREATING YOUR SPECIAL PLACE*

- Begin by closing your eyes and taking several slow, deep breaths.
- Imagine a place where you feel completely comfortable and peaceful. It may be a real place or one you imagine; one from your past or some place you have always wanted to go.
- Allow this special place to take form, slowly. As it takes form, look around, to your left, to your right. Enjoy the scenery: the colors, the texture, the shapes.
- Listen carefully to the sounds of your place. What do you hear?
- Is there a gentle breeze or sunshine warming your face? Pick up or touch some favorite objects from your special place.
- Take in a deep breath through your nose, and notice the rich smells around you. Perhaps your favorite flower is in bloom, or you smell the scents of the ocean.
- Take another deep breath and relax. Enjoy the peace, comfort, and safety of your special place.
- This is your special place. You relax and feel thankful that you are here, in your special place.
- You can return to this place any time that you wish.

*Evolve Imagery exercises are available in the Stress-Busting Kit for Nursing Students on the website for this book.

Imagery can also be used to enhance performance or process stressful or difficult tasks. For example, an athlete or musician can use imagery to achieve greater success. Imagery allows one to mentally rehearse the difficult or challenging situation. Imagery can help a fearful nurse start an IV line or perform a difficult procedure. It can also be used with a patient who is afraid to have a stressful procedure performed (e.g., radiation therapy).

Music for Relaxation

Music can help achieve relaxation and bring about healthy changes in emotional or physical states. Listening to relaxing music may divert one's focus from a stressful situation. In addition, healing vibrations from music can return the mind and body to a deeper level of balance.

FIG. 7-7 In imagery, special places are created involving all the senses, such as a place where one can hear rustling water, smell flowers, feel the wind, and see a colorful landscape. (iStockphoto/Thinkstock)

TABLE 7-8 EXAMPLES OF IMAGERY

Imagery can be used to relieve stress and promote health and healing in conjunction with regular medical care. Special images can be created to alleviate symptoms or treat diseases or disorders. The image should be strong and vivid for the person, using many senses to create the image. Below are some examples that some people have found useful.

Disease or Disorder	Images
Infection	• White blood cells with flashing red sirens arrest and imprison harmful germs.
Cancer	• Shark gobbles up cancer cells. • Radiation or chemotherapy treatments enter the body like healing rays of light; they destroy cancer cells.
Coronary artery disease	• Water flows freely through a wide, open river.
Weakened immune system	• White blood cells rapidly multiply like millions of seeds bursting from ripe seed pod.
Asthma	• Tiny elastic rubber bands that constrict the airways pop open.
Depression	• Troubles and feelings of sadness are attached to big colorful helium balloons and are floating off into a clear blue sky.
Pain	• Pain is washed away by a cool calm river flowing through the entire body.

Adapted from Sobel DS, Ornstein R: *Healthy mind, healthy body,* New York, 1996, Patient Education Materials, Time Life.

Music has been used in many clinical settings. Music decreases anxiety and evokes the relaxation response. This relaxation helps people with insomnia go to sleep. In oncology patients it has succeeded in decreasing muscular tension, pain sensation, and emotional stress associated with cancer. In general, music affects the heart rate, blood pressure, gastrointestinal secretions and motility, muscle tone, sweat glands, and skin temperature.[22]

Music that contains approximately 60 to 80 beats/min is considered soothing. Low-pitched tones and music without words is recommended for relaxation. Mozart's music is a popular form of music used for relaxation. On the other hand, fast-tempo music can stimulate and uplift a person. Each person considers different types of music to be relaxing, so it is important to find the music that best matches the person's needs and circumstance. To achieve optimal relaxation, minimize all interruptions and assume a comfortable posture while listening to music.

Music can be incorporated into clinical practice. It is noninvasive, safe, inexpensive, and easy to use. First, it is important to establish the purpose and benefit of using music with patients in a given clinical setting. Then assess each individual patient's interest and preference in music. Create a listening environment, encouraging the patient to find a comfortable position. Headphones or earphones and an MP3 or CD player can be used. Music can be played for 20 to 30 minutes per day at least twice a day. Evaluate patients' response to the music, asking them how it sounds and how it makes them feel.

Massage

Massage is another important relaxation strategy. It involves the systematic manipulation of the soft tissue of the body to reduce tension and enhance health and healing. It also meets an essential human need: touch. Massage can be implemented as back rubs for patients. Massage is discussed in more detail in Chapter 6.

You may not be able to change the stressors in your life, but you can change your reaction or response to them.
Florence Nightingale

NURSING MANAGEMENT STRESS

NURSING ASSESSMENT

As a nurse, you are in a key position to assess stress in patients and their caregivers, to assist them in identifying high-risk periods for stress, and to implement stress management strategies that can prevent the negative consequences of stress on their health (Fig. 7-8). Assess the number of stressors, the duration of these stressors, and previous experience with similar demands. Also assess the personal meaning attached to the stressful situation to provide useful insight for planning stress management strategies with the patient. Also consider family responses to the demands on the patient.

The patient faces many potential stressors that can have health consequences. Be aware of situations that are likely to result in stress, and determine the patient's perception of these situations. In addition to the stressor itself, specific coping strategies have health consequences and therefore must be included in the assessment.

Although the manifestations of stress may vary from person to person, assess the patient for the signs and symptoms of the stress response, including an increased heart rate and blood pressure, hyperventilation, sweating, headache, musculoskeletal pain, gastrointestinal upset, loss of appetite, skin disorders, insomnia, and fatigue. In addition, the patient may exhibit some of the stress-related illnesses or diseases of adaptation (see Table 7-2).

Behavioral manifestations may include an inability to concentrate, accident proneness, impaired speech, anxiety, crying, frustration, and irritability. Work-related responses to stress may include absenteeism or tardiness at work, decreased productivity, and job dissatisfaction. Cognitive responses include self-reports of an inability to make decisions and forgetfulness. Some of these responses may also be apparent to significant others.

Another major source of stress relates to the patient's illness, which often also causes stress for the caregiver and other family members. Assess what aspects of the illness are the most stressful for the patient. These may include the patient's physical health, job responsibilities, finances, and children. This information is valuable because it gives you the patient's perspective of the stressors. Knowledge of stressors, the feelings these stressors invoke, and the psychologic sequelae they can produce will assist you in identifying potential and actual sources of stress and their effect on the patient.

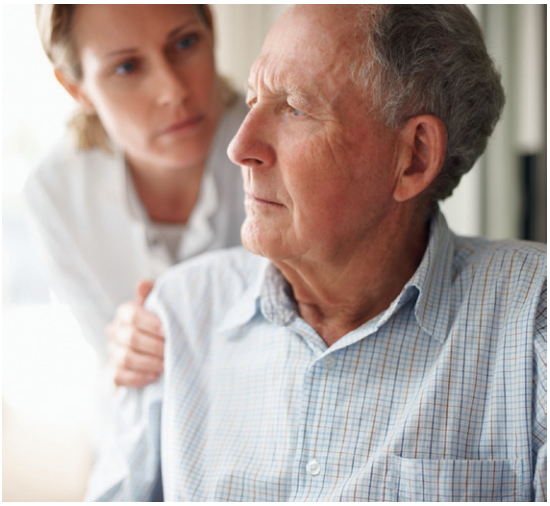

FIG. 7-8 As a nurse, you have an important role in helping patients deal with stress. (Hemera/Thinkstock)

COMPLEMENTARY & ALTERNATIVE THERAPIES

St. John's Wort

Scientific Evidence

- Although some studies of St. John's wort have reported benefits for depression, others have not.
- For treating major depression of moderate severity, a large study found that the herb was no more effective than a placebo.*
- For symptoms of minor depression, a study found that neither St. John's wort nor citalopram (Celexa), a prescription antidepressant, relieved symptoms better than a placebo.†

Nursing Implications

- Depression is a serious illness. Advise patients to consult with a health care provider before self-medicating with St. John's wort.
- St. John's wort is not a proven therapy for depression. If depression is not adequately treated, it can become severe. Anyone who may have depression should see a health care provider. Effective proven therapies are available.
- Serious interactions can occur with numerous herbs, supplements, over-the-counter drugs, or prescription drugs.
- St. John's wort interferes with the metabolism of drugs that use the cytochrome P450 enzyme system, including birth control pills, cyclosporine, carbamazepine, warfarin, midazolam, nifedipine, tricyclic antidepressants, simvastatin, and HIV drugs.
- Use of St. John's wort may lead to increased side effects when taken with other antidepressants.

*Hypericum Depression Trial Study Group: Effect of *Hypericum perforatum* (St. John's wort) in major depressive disorder: a randomized controlled trial, *JAMA* 287(14):1807, 2002.
†Rapaport MH, Nierenberg AA, Howland R, et al: The treatment of minor depression with St. John's wort or citalopram: failure to show benefit over placebo, *J Psych Res* 45:931, 2011.

NURSING IMPLEMENTATION

The first step in managing stress is to become aware of its presence. This includes identifying and expressing stressful feelings. Your role is to facilitate and enhance the patient's coping and adaptation. Nursing interventions depend on the severity of the stress experience. For example, a patient with multiple traumas expends energy in an attempt to physically survive. As a nurse, your efforts are directed to life-supporting interventions and to approaches aimed at reducing additional stressors for the patient. The patient with multiple traumas is much less likely to adapt or recover if faced with additional stressors such as sleep deprivation or an infection.

Coping resources and strategies that are used should be adaptive and not a source of additional stress for the patient. Coping resources and strategies were previously discussed in this chapter.

You can assume a primary role in implementing stress management strategies. Some personal tips for handling stress are presented in Table 7-9. These tips will benefit you personally and can be shared with patients. Ideas for how to incorporate stress management strategies into nursing practice are presented in Table 7-10. Although some may require additional training, many stress management strategies are within the scope of nursing practice. These include relaxation breathing, imagery, music for relaxation, exercise, massage, meditation, art therapy, and journaling. (Additional resources are listed at the

TABLE 7-9 PERSONAL TIPS FOR HANDLING STRESS

- Do not try to be superhuman.
- Learn to "let go" of things that are outside of your control.
- Learn acceptance of yourself.
- Exercise regularly.
- Share your feelings.
- Keep a sense of humor; laugh often.
- Learn relaxation breathing.
- Use imagery.
- Meditate or pray.
- Get adequate sleep
- Live a healthy lifestyle.
- Try to look at change as a positive challenge, not as a threat.
- Solve the little problems, since this can help you gain a feeling of control.
- Work to resolve conflicts with other people.
- If needed, get professional counseling.

end of the chapter and in the Stress-Busting Kit for Nursing Students on the website for this book.)

Before teaching stress management strategies to patients, you need to personally become familiar with them. Most relaxation strategies can be taught to patients in 10 to 15 minutes. To prepare for a relaxation training session, have the patient wear loose-fitting clothing, and ensure that the setting is private, comfortable, and free from distractions or noises. Choose a relaxation strategy to best suit the patient and the situation. Give directions calmly and slowly in short, simple sentences. End the session gradually so as to not disrupt the relaxation that was just elicited. Say a phrase such as, "I am going to count backward from five to one. With each number, you will feel more alert, but still feel at peace." After counting backward, instruct the patient to slowly open his or her eyes.

Effective stress management provides an individual a sense of control of the stressful situation. As stress management practices are incorporated into daily activities, the individual is able to increase his or her confidence and self-reliance and limit the emotional response to the stressful circumstances. Possessing a sense of control can deter the harmful effects from the stress response.

As a nurse, you are in an ideal situation to integrate stress management in clinical practice. You are also well equipped to develop and test the effectiveness of new approaches to manage stress and promote positive health outcomes. However, it is important to recognize when the patient or caregiver needs to be referred to a professional with advanced training in counseling.

TABLE 7-10 HOW TO IMPLEMENT STRESS MANAGEMENT IN PRACTICE

- Learn relaxation breathing. It is the easiest method of relaxation to use.
- Practice teaching relaxation breathing with peers, then patients.
- Pick coping strategies (see Table 7-4) and relaxation strategies that are appropriate for your clinical area.
- Practice using the strategy yourself. It becomes easier with time.
- Take advantage of opportunities to teach coping and relaxation strategies to patients.
- Anticipate setbacks. They provide feedback about what you are doing wrong. Do NOT quit!
- Attend seminars and workshops on stress management to learn more.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Kava

Scientific Evidence

Although scientific studies provide some evidence that kava may be beneficial for the management of anxiety, the U.S. Food and Drug Administration (FDA) has issued a warning that use of kava supplements has been linked to a risk of severe liver damage.

Nursing Implications

- Kava has been reported to cause liver damage, including hepatitis and liver failure (which can cause death).
- It should be avoided by patients with liver problems and patients taking medications that affect the liver.
- Kava has been associated with several cases of abnormal muscle spasm or involuntary muscle movements. Kava may interact with several drugs, including drugs used for Parkinson's disease.
- Long-term or heavy use of kava may result in scaly, yellowed skin.
- Avoid driving and operating heavy machinery while taking kava because the herb has been reported to cause drowsiness.

CASE STUDY

Stress-Induced Complaints

iStockphoto/Thinkstock

Patient Profile

K.F., a 43-year-old woman, recently moved to the United States from Turkey with her two teenage children. She has no family in the country and was recently divorced. She has taken a job as a waitress in a hectic restaurant and works as a seamstress out of her home in the evenings.

She has developed some unusual symptoms and comes to see the nurse practitioner at a community clinic. Although she states that she was in good health when she left Turkey, she now complains of fatigue, inability to sleep, and aches all over her body. Even when she is able to get some extra sleep, she still feels exhausted. Her co-worker told her she has fibromyalgia.

Discussion Questions

1. Consider K.F.'s situation and describe the stressors with which she is dealing. Describe the possible effects of these stressors on her health.
2. ***Priority Decision:*** What are the priority coping strategies that you should include in K.F.'s plan of care?
3. What limitations should be considered when discussing specific coping strategies?
4. What cultural considerations should be included in the plan of care?

Evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Determination of whether an event is a stressor is based on a person's
   - **a.** tolerance.
   - **b.** perception.
   - **c.** adaptation.
   - **d.** stubbornness.
2. The nurse recognizes that a patient with newly diagnosed breast cancer is using an emotion-focused coping process when she
   - **a.** joins a support group for women with breast cancer.
   - **b.** considers the pros and cons of the various treatment options.
   - **c.** delays treatment until her family can take a weekend trip together.
   - **d.** tells the nurse that she has a good prognosis because the tumor is small.

3. The nurse would expect which findings in a patient as a result of the physiologic effect of stress on the reticular formation?
   a. An episode of diarrhea while awaiting painful dressing changes
   b. Refusal to communicate with nurses while awaiting a cardiac catheterization
   c. Inability to sleep the night before beginning to self-administer insulin injections
   d. Increased blood pressure, decreased urine output, and hyperglycemia after a car accident
4. The nurse uses knowledge of the effects of stress on the immune system by encouraging patients to
   a. sleep for 10 to 12 hours per day.
   b. avoid exposure to upper respiratory tract infections.
   c. receive regular immunizations when they are stressed.
   d. use emotion-focused rather than problem-focused coping strategies.
5. The nurse recognizes that a person who is subjected to chronic stress could be at higher risk for
   a. osteoporosis.
   b. colds and flu.
   c. low blood pressure.
   d. high serum cholesterol.
6. During a stressful circumstance that is uncontrollable, which type of coping strategy is the most effective?
   a. Avoidance
   b. Coping flexibility
   c. Emotion-focused coping
   d. Problem-focused coping
7. An appropriate nursing intervention for a hospitalized patient who states she cannot cope with her illness is
   a. controlling the environment to prevent sensory overload and promote sleep.
   b. encouraging the patient's family to offer emotional support by frequent visiting.
   c. arranging for the patient to phone family and friends to maintain emotional bonds.
   d. asking the patient to describe previous stressful situations and how she managed to resolve them.

1. b, 2. a, 3. c, 4. b, 5. b, 6. c, 7. d.

LEARNING OUTCOMES

1. Define *sleep*.
2. Describe stages of sleep.
3. Explain the relationship of various diseases/disorders and sleep disorders.
4. Describe the etiology, clinical manifestations, and collaborative and nursing management of insomnia.
5. Describe the etiology, clinical manifestations, and collaborative and nursing management of narcolepsy.
6. Describe the etiology, clinical manifestations, collaborative care, and nursing management of obstructive sleep apnea.
7. Describe parasomnias, including sleepwalking, sleep terrors, and nightmares.
8. Select appropriate strategies for managing sleep problems associated with shift work sleep disorder.

SLEEP

Sleep is a state in which an individual lacks conscious awareness of environmental surroundings, but can be easily aroused. Sleep is distinct from unconscious states such as coma in which the individual cannot be aroused. Sleep is a basic, dynamic, highly organized, and complex behavior that is essential for healthy functioning and survival. Over a life span of 80 years, an individual who sleeps 7 hours each night will spend approximately 24 years sleeping. Sleep influences both behavioral and physiologic functions, including memory, mood, hormone secretion, glucose metabolism, immune function, and body temperature.

Most adults require 7 to 8 hours of sleep within a 24-hour period. Adequate sleep is defined as the amount of sleep one needs to be fully awake and alert the next day. *Insufficient sleep* refers to obtaining less than recommended amounts of sleep. *Fragmented sleep* refers to frequent arousals or actual awakenings that interrupt sleep continuity.

Sleep disturbance is a term used to indicate conditions of poor sleep quality. **Sleep disorders** are abnormalities unique to sleep. They can be classified as dyssomnias or parasomnias (Table 8-1). *Dyssomnia* is a term used to describe problems associated with initiating or maintaining sleep. Parasomnias are discussed later in this chapter on p. 110.

More than 70 million people in the United States have a sleep disorder, and many are unaware that they have a problem[1,2] (Fig. 8-1). On average most Americans report sleeping 6½ hours on workdays and 7½ hours on nonworkdays. Seventy percent of adults report habitually sleeping less than 7 hours a night.

Insufficient sleep is a serious problem with health consequences. In the 2011 National Sleep Foundation survey, 87% of Americans reported at least one sleep problem such as

difficulty falling asleep, fragmented sleep, or snoring a few nights per week.[3] Daytime sleepiness can be so severe that it interferes with work and social functioning (Fig. 8-2). People with chronic illnesses are at the greatest risk for sleep disturbances.

Many sleep disorders go untreated because health care providers do not ask and patients do not talk about sleep problems. Untreated sleep disorders pose considerable health and economic consequences. Driving while drowsy is related to 100,000 accidents and 1500 traffic fatalities per year.[4] Each year, sleep disorders, sleep loss, and excessive daytime sleepiness cost the United States billions of dollars from the cost of health care, work-related accidents, and lost productivity.[1]

PHYSIOLOGIC SLEEP MECHANISMS

Sleep-Wake Cycle

The brain controls the cyclic changes between sleep and waking, but no single structure regulates these states. Rather, complex networks in the brainstem, hypothalamus, and thalamus interact to regulate the sleep and wake cycle.

Wake Behavior. **Wake behavior** is maintained by an integrated network of arousal systems from the brainstem and basal forebrain. A cluster of neuronal structures in the middle of the brainstem, called the reticular activating system (RAS), is associated with generalized cortical activation and behavioral arousal. Various neurotransmitters (glutamate, acetylcholine, norepinephrine, dopamine, histamine, serotonin) promote wake behavior.[5]

People with Alzheimer's disease have a loss of cholinergic neurons in the basal forebrain, which results in sleep disturbances. People with Parkinson's disease have degeneration of dopamine neurons in the substantia nigra, leading to excessive daytime sleepiness. Histamine neurons in the hypothalamus stimulate cortical activation and wake behavior. The sedating properties of many over-the-counter (OTC) medications result from inhibiting one of these arousal systems.

Orexin (also called hypocretin), a neuropeptide, is found in the lateral hypothalamus. Orexin activates arousal systems and simultaneously inhibits sleep active neurons. Decreased levels of orexin or its receptors lead to difficulties staying awake and the syndrome called *narcolepsy*. (Narcolepsy is discussed later in this chapter on pp. 106-107.)

Sleep Behavior. An area in the hypothalamus just above the optic chiasm contains many sleep-promoting neurons. These neurons act to inhibit the RAS and promote sleep.[5] Sleep is stimulated by a variety of sleep-promoting neurotransmitters and peptides, including γ-aminobutyric acid (GABA), galanin, melatonin, adenosine, somatostatin, growth hormone–releasing hormone, delta-sleep–inducing peptide, prostaglandins, and proinflammatory cytokines (interleukin-1, tumor necrosis factor, interleukin-6). Proinflammatory cytokines are important in mediating sleepiness and lethargy associated with infection. Peptides, such as cholecystokinin, released by the gastrointestinal tract after food ingestion may mediate the sleepiness *(postprandial sleepiness)*.

Melatonin is an endogenous hormone produced by the pineal gland in the brain from the amino acid tryptophan. Melatonin secretion is tightly linked to the environmental light-dark cycle. Under normal day-night conditions, melatonin is released in the evening as it gets dark. Light exposure at night can suppress melatonin secretion.[6]

Circadian Rhythms. Many biologic rhythms of behavior and physiology fluctuate within a 24-hour period. Because the **circadian** (*circa dian,* about a day) **rhythms** are controlled by internal clock mechanisms, they persist when people are placed in environments free of external time cues. The suprachiasmatic nucleus (SCN) in the hypothalamus is the master clock of the body. The 24-hour cycle of sleep and wake is synchronized to the environmental light and dark periods through specific light detectors in the retina. Pathways from the retina reach the SCN, and pathways from the SCN innervate brain regions controlling wake and sleep behavior.[5]

Light is the strongest time cue for the sleep-wake rhythm. Thus light can be used as a therapy to shift the timing of the sleep-wake rhythm. For example, bright light used early in the morning will cause the sleep-wake rhythm to move to an earlier time; bright light used in the evening will cause the sleep-wake rhythm to move to a later time.

Sleep Architecture

Sleep architecture refers to the pattern of nighttime sleep recorded from physiologic measures of brain waves, eye movements, and muscle tone called *polysomnography* (PSG). Sleep consists of two basic states: rapid eye movement (REM) sleep and non–rapid eye movement (NREM) sleep (see eFig. 8-1 on the website for this chapter). During sleep, the body cycles between NREM and REM sleep. Once asleep, a person goes through four to six NREM and REM sleep cycles.[7]

NREM Sleep. In healthy adults the largest percentage of total sleep time, approximately 75% to 80%, is spent in NREM sleep. NREM sleep is subdivided into three stages:[8]

Stage 1 occurs in the beginning of sleep, with slow eye movements, and is a transition phase from wakefulness to sleep. During this period the person can be easily awakened.

Stage 2 encompasses most of the night's sleep. The heart rate slows down, and the body temperature drops. This stage is associated with specific electroencephalographic (EEG) wave forms that help to maintain sleep.

Stage 3 is deep sleep or slow-wave sleep (SWS). This stage is associated with large EEG wave forms, called delta waves, which are used as a measure of sleep intensity. SWS sleep declines as people age such that most adults over 60 years of age have little NREM stage 3 sleep.

REM Sleep. REM sleep accounts for 20% to 25% of sleep. REM sleep follows NREM sleep in a sleep cycle (see eFig. 8-1). In this stage brain waves resemble wakefulness and postural muscles are inhibited, leading to greatly reduced skeletal muscle tone. During REM sleep an individual cannot stand up and move around. REM sleep is the period when the most vivid dreaming occurs.

INSUFFICIENT SLEEP AND SLEEP DISORDERS

Insufficient sleep and sleep disorders are associated with changes in body function (Fig. 8-3) and health problems (Table 8-2). Impaired cognitive function and impaired performance on simple behavioral tasks occur within 24 hours of sleep loss. The effects of sleep loss are cumulative. Individuals who report less than 6 hours of sleep a night have a higher body mass index (BMI) and are more likely to be obese. The risk for developing glucose intolerance and diabetes is increased in individuals with a history of insufficient sleep.[9,10] Chronic loss of sleep

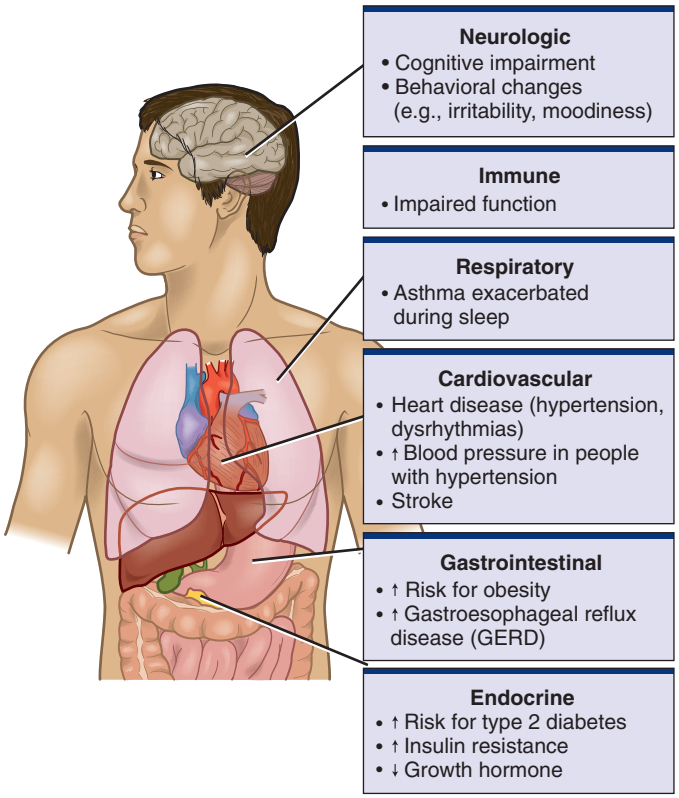

FIG. 8-3 Effects of sleep deprivation and sleep disorders on the body.

places older adults at risk for depression, impaired daytime functioning, social isolation, and overall reduction in quality of life. In patients with chronic illnesses, especially cardiovascular disease and stroke, insomnia and sleep-disordered breathing are associated with increased morbidity and mortality.[11,12]

INSOMNIA

The most common sleep disorder is insomnia. **Insomnia** is characterized by difficulty falling asleep, difficulty staying asleep, waking up too early, or complaints of waking up feeling unrefreshed. Insomnia is a common problem; one in three adults experiences insomnia.

Acute insomnia refers to difficulties falling or remaining asleep at least 3 nights per week for less than a month. *Chronic insomnia* is defined by the same symptoms and a daytime complaint (e.g., fatigue, poor concentration, interference with social or family activities) that persist for 1 month or longer. Chronic insomnia occurs in 10% to 15% of Americans and is more common in women than men.[13] Chronic insomnia increases with age up to about age 65. Insomnia rates are higher in divorced, widowed, and separated individuals than in those who are married. Insomnia is more prevalent in individuals with low socioeconomic status and less education.[12,13]

Etiology and Pathophysiology

Behaviors, lifestyle, diet, physical and mental conditions, and medications contribute to insomnia. *Inadequate sleep hygiene* refers to those practices or behaviors that are inconsistent with good quality sleep. Intake of stimulants (e.g., caffeine, nicotine, methamphetamine), especially in the evening hours, predisposes a person to insomnia. Insomnia is a common side effect

TABLE 8-2 RELATIONSHIP OF SLEEP DISTURBANCES TO DISEASES AND DISORDERS

Disease or Disorder	Sleep Disturbance
Respiratory	
Asthma	• Exacerbated during sleep.
Chronic obstructive pulmonary disease (COPD)	• Associated with poor sleep quality, nocturnal oxygen desaturation, and coexisting sleep apnea.
Obstructive sleep apnea	• Linked with heart disease (hypertension, stroke, coronary artery disease, dysrhythmias). • Results in impaired glucose control similar to that which occurs in type 2 diabetes.
Renal	
End-stage kidney disease	• Disrupted nocturnal sleep with excessive daytime sleepiness. • Patients on dialysis have a high incidence of SDB and RLS, which are both significant predictors of mortality in these patients.
Immune Disorders	
Human immunodeficiency virus (HIV)	• Sleep disturbances and fatigue highly prevalent and associated with survival.
Endocrine	
Diabetes	• Insufficient sleep linked to increased risk for type 2 diabetes. • Sleep deprivation in healthy people increases insulin resistance. • Sleep duration and quality are predictors of Hb A1C levels, an important marker of blood glucose control.
Musculoskeletal	
Arthritis	• Increased rates of RLS and SDB. • Disease activity linked to sleep complaints.
Fibromyalgia	• Co-morbid insomnia, especially complaint of nonrestorative sleep. • Increased rates of PLMD and RLS. • Lower concentrations of sleep-dependent hormones (growth hormone, prolactin).
Chronic fatigue syndrome	• Co-morbid insomnia. • Increased rates of SDB.
Cardiovascular (CV)	
	• People with sleep apnea or sleep disorders are at increased risk for CV disorders, including hypertension, dysrhythmias, and coronary artery disease.
Heart failure (HF)	• Sleep disturbances (insomnia, PLMD, SDB) are common. • Cheyne-Stokes breathing and central apnea are signs of HF exacerbation related to fluid overload.
Hypertension	• Inadequate sleep in people with hypertension can lead to further elevations in BP.
Gastrointestinal	
Obesity	• Association between short sleep duration and excess body weight. Short sleep duration may result in metabolic changes that are linked to obesity. • Higher BMI in people who sleep <6 hours, compared with people who sleep >8 hours. • Risk factor for SDB.
Gastroesophageal reflux disease (GERD)	• Reflux of gastric contents into the esophagus occurs during sleep because of incompetent lower esophageal sphincter. • Swallowing is depressed during sleep.
Chronic liver disease	• Associated with excessive sleepiness, nocturnal arousal, and RLS.
Neurologic	
Parkinson's disease	• Associated with difficulty initiating or maintaining sleep, parasomnias, and excessive daytime sleepiness.
Alzheimer's disease	• Many have SDB (frequently sleep apnea). • Circadian rhythm alterations with nocturnal wandering, daytime sleepiness, and sleep disruption and awakening.
Pain (acute and chronic)	• Decreased quantity and quality of sleep. Poor sleep can intensify pain.
Cancer	• Higher rates of insomnia. • Chemotherapy for cancer treatment associated with fragmented sleep and fatigue.

BMI, Body mass index; *PLMD*, periodic limb movement disorder; *RLS,* restless legs syndrome; *SDB,* sleep-disordered breathing.

of many medications (e.g., antidepressants, antihypertensives, corticosteroids, psychostimulants, analgesics). Insomnia is exacerbated or perpetuated by drinking alcohol to help induce sleep, smoking close to bedtime, taking long naps in the afternoon, sleeping late in the morning, having nightmares, exercising near bedtime, and having jet lag.

Chronic insomnia is classified as primary or co-morbid. *Primary insomnia* is difficulty in initiating and maintaining sleep, resulting in poor daytime functioning that is not explained by other causes. The diagnosis of primary insomnia occurs after medical, neurologic, and psychiatric causes have been excluded.[14] The cause of primary insomnia is not known.

Certain individuals may be genetically predisposed or have psychologic traits that make them vulnerable to insomnia. Often individuals report that the onset occurred after a stressful life event (e.g., loss of loved one).

Co-morbid insomnia is common. It is associated with psychiatric illnesses, medical conditions (see Table 8-2), medications, or substance abuse. Patients with psychiatric or medical conditions are 2 times more likely to have insomnia than individuals without these conditions.[15]

Once chronic insomnia manifests, symptoms are likely to persist over time. Individuals may perpetuate disturbed sleep by keeping irregular sleep-wake schedules, using OTC medications or alcohol as sleep aids, and spending more time in bed trying to sleep. Increased attention to one's environment, worry or fear about not obtaining sufficient sleep, and poor sleep habits can lead to arousal that becomes associated with the bed and bedroom. This is called *conditioned arousal.*

Clinical Manifestations

Manifestations of insomnia include one or more of the following symptoms: (1) difficulty falling asleep *(long sleep latency),* (2) frequent awakenings *(fragmented sleep),* (3) prolonged nighttime awakenings or awakening too early and not being able to fall back to sleep, and (4) awakening feeling unrefreshed, called *nonrestorative sleep.* Daytime consequences of insomnia include feeling tired, having trouble concentrating at work or school, and having an altered mood. Falling asleep during the day or complaints of sleepiness are common. Behavioral manifestations of poor sleep include irritability, forgetfulness, confusion, and anxiety.

Diagnostic Studies

Self-Report. The diagnosis of insomnia is made based on subjective complaints and on an evaluation of a 1- or 2-week sleep diary completed by the patient. In ambulatory care settings the evaluation of insomnia requires a comprehensive sleep history to establish the type of insomnia and to screen for possible psychiatric, medical, or other sleep disorders that would require specific treatment. Questionnaires such as the Pittsburgh Sleep Quality Index (see eTable 8-1 on the website for this chapter), Insomnia Severity Index (see eTable 8-2), and Epworth Sleepiness Scale (see eTable 8-3) are commonly used to assess sleep quality.[16-18]

Actigraphy. Actigraphy is a relatively noninvasive method of monitoring rest and activity cycles. A small actigraph watch can be worn on the wrist to measure gross motor activity. The unit continuously records the patient's movements, producing data that are downloaded to a computer and analyzed.

Polysomnography. A clinical PSG study is not required to establish a diagnosis of insomnia. A PSG study is done only if there are symptoms or signs of another sleep disorder, such as sleep-disordered breathing (discussed later in the chapter). In a PSG study, electrodes simultaneously record physiologic measures that define the main stages of sleep and wakefulness.[7,8] These measures include (1) muscle tone recorded using an electromyogram (EMG), (2) eye movements recorded with an electro-oculogram (EOG), and (3) brain activity recorded through EEG. To determine additional characteristics of specific sleep disorders, other measures made during PSG include airflow at the nose and mouth, respiratory effort around the chest and abdomen, heart rate, noninvasive oxygen saturation, and EMG of the anterior tibialis muscles (used to detect periodic leg movements). Finally, a patient's gross body movements are monitored continuously by audiovisual means.

Collaborative Care

Insomnia treatments are oriented toward symptom management (Table 8-3). A key to management is to change behaviors that perpetuate insomnia. An important first step is to provide teaching about sleep along with behavioral strategies. **Sleep hygiene** is a variety of different practices that are important to have normal, quality nighttime sleep and daytime alertness (Table 8-4).

Cognitive-Behavioral Therapy for Insomnia. Although teaching about sleep hygiene practices is useful, individuals with chronic insomnia require more in-depth cognitive-behavioral therapy for insomnia (CBT-I).[14] CBT-I is based on structured treatment plans that could include relaxation training, guided imagery, cognitive strategies to address misconceptions about sleep, and behavioral strategies. Behavioral strategies for insomnia include instructions to (1) limit the amount of time an individual can stay in bed, (2) maintain a scheduled

TABLE 8-4 PATIENT TEACHING GUIDE

Sleep Hygiene

Include the following instructions when teaching a patient who has a sleep disturbance or disorder.

- Don't go to bed unless you are sleepy.
- If you are not asleep after 20 minutes, get out of the bed.
- Adopt a regular pattern in terms of bedtime and awakening.
- Begin rituals (e.g., warm bath, light snack, reading) that help you relax each night before bed.
- Get a full night's sleep on a regular basis.
- Make your bedroom quiet, dark, and a little bit cool.
- Don't read, write, eat, watch TV, talk on the phone, or play cards in bed.
- Avoid caffeine, nicotine, and alcohol at least 4 to 6 hours before bedtime.
- Don't go to bed hungry, but don't eat a big meal near bedtime either.
- Avoid strenuous exercise within 6 hours of your bedtime.
- Avoid sleeping pills, or use them cautiously.
- Practice relaxation techniques (e.g., relaxation breathing) to help you cope with stress in your life (see Chapter 7).

TABLE 8-5 DRUG THERAPY

Insomnia

Benzodiazepines
- diazepam (Valium)
- flurazepam (Dalmane)
- lorazepam (Ativan)
- quazepam (Doral)
- triazolam (Halcion)

Benzodiazepine-Receptor–like Agents
- zolpidem (Ambien, Ambien CR, Intermezzo, Edluar, ZolpiMist)
- zaleplon (Sonata)
- eszopiclone (Lunesta)

Melatonin-Receptor Agonist
- ramelteon (Rozerem)

Antidepressants
- amitriptyline (Elavil)
- bupropion (Wellbutrin)
- doxepin (Sinequan)
- fluoxetine (Prozac)
- trazodone (Desyrel)

Antihistamines
- diphenhydramine (Benadryl, Nytol, Sominex)

time to get up in the morning, (3) go to bed only when an individual feels sleepy, and (4) get out of bed when unable to sleep. CBT-I also includes teaching about sleep hygiene practices (see Table 8-4). CBT-I requires individuals to change behavior, which sometimes is difficult.

Encourage individuals with insomnia not to watch television or read in bed. Time in bed is limited to the actual time that the individual can sleep. Teach the person with insomnia to avoid naps and consumption of large meals, alcohol, and stimulants, especially a few hours before bedtime. Naps are less likely to affect nighttime sleep if they are limited to 15 to 20 minutes, once per day, and scheduled 7 to 9 hours after morning awakening. Regular exercise (performed several hours before bedtime) may enhance sleep quality.

Drug Therapy. Hypnotic and anxiolytic medications are effective for improving sleep, but the benefits for improving daytime functioning are less certain. Few studies have evaluated the use of hypnotics for chronic insomnia, and their use in older adults is controversial.[19] Many individuals with insomnia become used to taking OTC or prescription medications to treat insomnia and risk becoming dependent on them, both psychologically and physically.[20] *Rebound insomnia* is common with abrupt withdrawal of some hypnotic medications. The resulting daytime fatigue can negatively influence the patient's efforts to use nondrug approaches. Classes of medications used to treat insomnia include benzodiazepines, benzodiazepine-receptor–like agents, melatonin-receptor agonists, and antidepressant and antihistamine medications (Table 8-5).

Benzodiazepines. Benzodiazepines such as diazepam (Valium) activate the γ-aminobutyric acid (GABA) receptors to promote sleep. The prolonged half-life of some of these agents (e.g., flurazepam [Dalmane]) can result in daytime sleepiness, amnesia, dizziness, and rebound insomnia. Tolerance to these agents develops, and there is risk for dependence. It is recommended that the use of benzodiazepines be limited to 2 to 3 weeks. All benzodiazepines have the potential for abuse. In addition, benzodiazepines interact with alcohol and other central nervous system (CNS) depressants. These agents are no longer recommended as first-line therapy for insomnia.

Benzodiazepine-Receptor–like Agents. Zolpidem (Ambien), zaleplon (Sonata), and eszopiclone (Lunesta) are the drugs of first choice for insomnia. Because they are benzodiazepine-receptor agonists, they work similarly to benzodiazepines.[20] These drugs are effective and safe for use from 6 months to a year. Food has the potential to delay onset of action and should not be taken with these agents. These agents have short half-lives, making their duration of action short. The extended-release formulation of zolpidem (Ambien CR) is used for problems of sleep onset and sleep maintenance. A dissolvable tablet form of zolpidem (Edluar) and an oral spray formulation (ZolpiMist) may be useful for individuals who have difficulty swallowing pills or are on restricted oral fluid intake.[20] Zolpidem tartrate (Intermezzo), a sublingual tablet, is used for patients with insomnia characterized by middle-of-the-night waking followed by difficulty returning to sleep.

Melatonin-Receptor Agonist. Ramelteon (Rozerem) is a melatonin-receptor agonist. It has a rapid onset that is effective for sleep onset but a short duration of action. Unlike benzodiazepines, ramelteon does not cause tolerance, but the drug is not always effective in improving sleep quality.[19]

Antidepressants. Trazodone (Desyrel) is an atypical antidepressant that has sedative properties. It is one of the most common agents prescribed in the United States to treat insomnia, especially in older adults. The insomnia dose of antidepressants like trazodone is much lower than the antidepressant dose. The administration of this drug to older adults is controversial. Daytime sleepiness is a common side effect. Tolerance can develop within a few weeks.

Doxepin (Sinequan) is another antidepressant used to treat insomnia. In very low doses doxepin inhibits histamine receptors in the brain. Doxepin improves sleep without next-day drowsiness in older and middle-aged adults with chronic primary insomnia.[21]

Antihistamines. Many individuals with insomnia self-medicate with OTC sleep aids. Most OTC agents include diphenhydramine (Benadryl, Nytol, Sominex). These agents are less effective than benzodiazepines, and tolerance develops quickly. In addition, antihistamines have anticholinergic side effects, including daytime sleepiness, impaired cognitive function, blurred vision, urinary retention, constipation, and risk of increased intraocular pressure. Agents with diphenhydramine are not intended for long-term use and should not be used by older adults.[11,19]

Complementary and Alternative Therapies. Many types of complementary therapies and herbal products are used as sleep aids. As noted earlier in the chapter, melatonin is a hormone produced by the pineal gland[22] (see Complementary & Alternative Therapies box). Melatonin is effective for improving sleep disturbance associated with jet lag. It also helps night shift

COMPLEMENTARY & ALTERNATIVE THERAPIES

Melatonin

Scientific Evidence

Overall, the scientific evidence suggests the benefits of melatonin in people who take it for jet lag. The majority of scientific evidence suggests that it may decrease the time it takes to fall asleep (sleep latency).

Nursing Implications
- Regarded as safe in recommended doses for short-term use.
- Avoid in patients using warfarin (Coumadin).
- Avoid in patients using central nervous system depressants.
- May cause a drop in blood pressure. Caution is advised in patients taking drugs that may also lower blood pressure.

workers sleep during the daytime. However, melatonin is not considered effective for improving nighttime sleep. Valerian is an herb that has been used for many years as a sleep aid and to relieve anxiety. Although valerian is safe, it is not effective in treating insomnia.[23]

NURSING MANAGEMENT INSOMNIA

NURSING ASSESSMENT

As a nurse, you are in a key position to assess sleep problems in patients and their caregivers. Sleep assessment is important in helping patients identify personal habits and environmental factors that contribute to poor sleep. Family caregivers may experience sleep disruptions due to the necessity of providing care to patients in the home. These sleep disruptions can increase the burden of caregiving.

Both self-report and objective data are used to assess sleep duration and quality. Many patients do not tell their health care provider about their sleep problems. Therefore all patients should be asked about their sleep on a regular basis. A sleep history includes characteristics of sleep such as the duration, the pattern of sleep, and daytime alertness. Before using any questionnaire, assess the patient's cognitive function, reading level (if a paper form is used), and language ability (Table 8-6). Also assess the diet. Question the patient about the intake of caffeine and other food stimulants (chocolate). Ask about alcohol consumption and whether it is used as a sleep aid.

Ask the patient about sleep aids. This includes both OTC and prescription medications. Note the drug dose, frequency of use, and any side effects (e.g., daytime drowsiness, dry mouth). Many individuals also consume herbal or dietary supplements that they believe improve sleep, including valerian, melatonin, hops, lavender, passion flower, kava, and skullcap. Inform the patient that many of these products are sold as dietary supplements and do not have U.S. Food and Drug Administration (FDA) approval or regulatory oversight. The exact components and concentrations of herbs and supplements often are unknown, and patients may experience adverse effects. Certain agents such as kava are associated with liver toxicity. Additional sleep aids include white noise devices or relaxation strategies.

Encourage individuals to keep a sleep diary for 2 weeks. In the diary they record when they go to sleep, when they wake up, and how long they were awake during the night (see eTable 8-4 on the website for this chapter). The number and duration of naps are also recorded. Standardized questionnaires such as the Epworth Sleepiness Scale (see eTable 8-3) may be used to assess daytime sleepiness.[18]

The patient's medical history can also provide important information about factors that contribute to poor sleep. For example, men with benign prostatic hyperplasia often report frequent awakenings during the night for voiding. Psychiatric problems (e.g., depression, anxiety, posttraumatic stress disorder [PTSD], drug abuse) are associated with sleep disturbances. Sleep disturbances often develop as a consequence or complication of a chronic or terminal condition (e.g., heart disease, dementia, cancer).[14]

Ask about work schedules and cross-country and international travel. Shift work contributes to reduced or poor-quality sleep. Work-related behaviors resulting from poor sleep may include poor performance, decreased productivity, and job absenteeism.

TABLE 8-6 NURSING ASSESSMENT

Sleep

Use the following questions to do an initial assessment regarding sleep.

1. What time do you normally go to bed at night? What time do you normally wake up in the morning?
2. Do you often have trouble falling asleep at night?
3. About how many times do you wake up at night?
4. If you do wake up during the night, do you usually have trouble falling back asleep?
5. Does your bed partner say or are you aware that you frequently snore, gasp for air, or stop breathing?
6. Does your bed partner say or are you aware that you kick or thrash about while asleep?
7. Are you aware that you ever walk, eat, punch, kick, or scream during sleep?
8. Are you sleepy or tired during much of the day?
9. Do you usually take one or more naps during the day?
10. Do you usually doze off without planning to during the day?
11. How much sleep do you need to feel alert and function well?
12. Are you currently taking any type of medication or other preparation to help you sleep?

NURSING DIAGNOSES

Specific nursing diagnoses related to sleep include insomnia, sleep deprivation, disturbed sleep pattern, and readiness for enhanced sleep.

NURSING IMPLEMENTATION

Nursing interventions depend on the severity and duration of the sleep problem, as well as individual characteristics. Optimally, healthy adults should have 7 to 8 hours of sleep a night. Individuals with longer (more than 9 hours) and shorter (less than 6 hours) sleep durations have increased morbidity and mortality risks. Those with short sleep duration have increased risk for weight gain, impaired glucose tolerance and diabetes, hypertension, cardiovascular disease, and stroke. Occasional difficulty getting to sleep or awakening during the night is not unusual. However, sleep disturbances longer than 1 month are problematic.

Although teaching about sleep hygiene practices (see Table 8-4) is beneficial, individuals with chronic insomnia require more in-depth intervention using CBT-I strategies. An important component of sleep hygiene is reducing dietary intake of substances containing caffeine (Table 8-7). Caffeine has a half-life of about 6 hours, perhaps as long as 9 hours, in older adults. Consuming caffeinated beverages after 12 o'clock should be avoided.

Suggest and implement changes in home and institutional environments to enhance sleep. Reducing light and noise levels enhances sleep. Awareness of time passing and watching the clock adds to anxieties about not falling asleep or returning to sleep. Keeping the bedroom dark and cool is conducive to good sleep.

Teach patients about sleeping medications. With the benzodiazepines, benzodiazepine receptor–like agents, and melatonin-receptor agonists, teach the patient to take the drug right before bedtime, be prepared to get a full night's sleep of at least 6 to 8 hours, and not plan activities the next morning that require

TABLE 8-7 CAFFEINE CONTENT OF SELECTED FOODS AND BEVERAGES

Food or Beverage	Caffeine (mg)
Coffee, brewed (8 oz)	95-200
Coffee, instant (8 oz)	27-173
Coffee, decaffeinated	5
Tea, leaf or bag (8 oz)	50
Celestial Seasoning herbal tea, all varieties	0
Diet Coke (12 oz)	47
Coca-Cola (12 oz)	35
Dr. Pepper (12 oz)	54
Pepsi-Cola (12 oz)	37
7-Up, Sprite, or Diet 7-Up (12 oz)	0
A&W Root Beer (12 oz)	0
Red Bull (12 oz)	80
Mountain Dew (12 oz)	55
Ben & Jerry's no-fat coffee fudge frozen yogurt (1 cup)	85
Dannon coffee yogurt (8 oz)	45
Hershey's special dark chocolate bar (1.5 oz)	31
Hershey bar (milk chocolate) (1.5 oz)	12
Hot chocolate (8 oz)	5

highly skilled psychomotor coordination. Advise patients not to take these medications with high-fat food (delays absorption), alcohol, or other CNS depressants.

Patient follow-up regarding medications is important. Ask about daytime sleepiness, nightmares, and any difficulties in activities of daily living.

SLEEP DISTURBANCES IN THE HOSPITAL

Hospitalization, especially in the intensive care unit (ICU), is associated with decreased total sleep time and decreased SWS and REM sleep.[24] Because of the nature of a critical illness and its treatment, sleep loss may be inevitable for patients in ICUs. Preexisting sleep disorders may be aggravated or triggered in the hospital. Patients with sleep apnea should use continuous positive airway pressure (CPAP) in the hospital. Sleep-disordered breathing is a major concern in the ICU.

Environmental sleep-disruptive factors, psychoactive medications, and acute and critical illness all contribute to poor sleep. Patient symptoms, including pain, dyspnea, and nausea, can also contribute to sleep loss in the acutely ill patient. Medications commonly used in acutely and critically ill patients can further contribute to sleep loss. Hospitalized patients are also at risk for poor sleep because of circadian rhythm disruptions and reduced melatonin levels. The hospital is a new environment and thus normal cues linked to sleep are absent.

Hospital and ICU noise (e.g., staff paging system, respirator alarms, bedside monitors, infusion alarms) and especially staff conversations near patients (e.g., in hallways) during both the day and night disturb sleep. Bright lights during the night also disrupt sleep and reduce melatonin levels. Patient care activities (e.g., dressing changes, blood draws, vital sign monitoring) disrupt sleep. Inactivity, boredom, and certain medications lead to napping during the day and evening that can affect nighttime sleep.

Decreased sleep duration and sleep loss influence pain perception.[25] Psychologic factors, such as anxiety and depression, also modify the sleep-pain relationship. Adequate pain management may improve total sleep time, but medications commonly used to relieve pain, especially opioids, also alter sleep and place an individual at risk for sleep-disordered breathing. Withdrawal of opioids is associated with rebound effects on sleep architecture.

You have an important role in creating an environment conducive to sleep. This includes the scheduling of medications and procedures. Reducing light and noise levels can promote opportunities for sleep. Hypnotic medications are often available on an as-needed basis. Ask patients if they would like medication to help them sleep.

NARCOLEPSY

Narcolepsy is a chronic neurologic disorder caused by the brain's inability to regulate sleep-wake cycles normally. At various times throughout the day, people with narcolepsy experience uncontrollable urges to sleep. As the urge becomes overwhelming, individuals fall asleep for periods lasting from a few seconds to several minutes. Patients with narcolepsy often go directly into REM sleep from wakefulness. This is a unique feature of narcolepsy. Patients with narcolepsy also experience fragmented and disturbed nighttime sleep.[26]

In both genders the onset of narcolepsy typically occurs in adolescence or early in the third decade. However, approximately 25% of the patients are not diagnosed until after 40 years of age. Head trauma, a sudden change in sleep-wake habits, and infection may trigger the onset of narcolepsy symptoms. Patients with narcolepsy are included in the Americans with Disabilities Act, which requires employers to provide reasonable accommodations for all employees with disabilities.

Narcolepsy has two categories: with and without cataplexy. **Cataplexy** is a brief and sudden loss of skeletal muscle tone or muscle weakness. It can manifest as a brief episode of muscle weakness or complete postural collapse and falling. Laughter, anger, or surprise often triggers episodes. Approximately 30% to 50% of patients with narcolepsy experience cataplexy.[27]

Etiology and Pathophysiology

The cause of narcolepsy remains unknown. It is associated with a deficiency of orexin (hypocretin), a neuropeptide linked to waking, from the destruction of orexin neurons. The reason for the loss of neurons is not well understood, but an autoimmune process is suspected.

Clinical Manifestations and Diagnostic Studies

Manifestations in some patients include brief episodes of sleep paralysis, hallucinations, cataplexy, and fragmented nighttime sleep. *Sleep paralysis* is a temporary (few seconds to minutes) paralysis of skeletal muscles (except respiratory and extraocular muscles) that occurs in the transition from REM sleep to waking. The loss of muscle tone, often triggered by strong emotions, usually lasts less than 2 minutes. During the period of muscle tone loss, the individual remains conscious.

With narcolepsy, unwanted episodes of REM sleep occur throughout the day. These sleep episodes are usually of short duration, but can last for more than 1 hour, and patients feel refreshed afterward. Patients may complain of feeling drowsy and being unable to remain awake while watching a movie, sitting in a classroom, reading, or performing other sedentary activities. As a result, they often show poor performance at work, have reduced quality of life, and experience poor interpersonal relationships.

TABLE 8-8 DRUG THERAPY

Narcolepsy

Wakefulness Promoting
- dextroamphetamine (Dexedrine)
- methamphetamine (Desoxyn)
- methylphenidate (Concerta)
- modafinil (Provigil)

Gabaminergic
- sodium oxybate or γ-hydroxybutyrate (Xyrem)

Antidepressants

Tricyclic
- atomoxetine (Strattera)
- protriptyline (Vivactil)
- desipramine (Norpramin)

Selective Serotonin Reuptake Inhibitors (SSRIs)
- fluoxetine (Prozac)
- venlafaxine (Effexor)

Narcolepsy is diagnosed based on a history of sleepiness, PSG, and daytime *multiple sleep latency tests* (MSLTs). For the MSLT, patients undergo an overnight PSG evaluation followed by four or five naps scheduled every 2 hours during the next day. Short sleep latencies and onset of REM sleep in more than two MSLTs are diagnostic signs of narcolepsy.

Nursing and Collaborative Management

Management of narcolepsy is focused on symptom management (see Table 8-3). Provide teaching about sleep and sleep hygiene. Advise the patient with narcolepsy to take three or more short (15 minute) naps throughout the day and to avoid large or heavy meals and alcohol. You can play a key role in ensuring patient safety by teaching safety behaviors and encouraging adherence to the prescribed medication regimen.

Drug Therapy. Narcolepsy cannot be cured. However, excessive daytime sleepiness and cataplexy (the most disabling manifestation of the disorder) can be controlled in most patients with drug treatment. A nonamphetamine wake-promotion drug, modafinil (Provigil), is considered a first-line drug therapy for narcolepsy. Other agents, including amphetamine drugs such as dextroamphetamine (Dexedrine), methamphetamine (Desoxyn), and methylphenidate (Concerta), are used to manage daytime sleepiness[28] (Table 8-8). Tricyclic antidepressant drugs such as atomoxetine (Strattera), protriptyline (Vivactil), and desipramine (Norpramin) are effective in the management of cataplexy. High doses of selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine (Prozac) and venlafaxine (Effexor) may be prescribed for management of cataplexy. Sodium oxybate, or γ-hydroxybutyrate (Xyrem), a metabolite of GABA, is also used in the treatment of narcolepsy.[28]

Behavioral Therapy. None of the current drug therapies cures narcolepsy or allows patients to consistently maintain a full, normal state of alertness. As a result, drug therapy needs to be combined with various behavioral strategies. The behavioral therapies for insomnia (discussed earlier in this chapter) are also used for patients with narcolepsy.

Safety precautions, especially when driving, are critically important for patients with narcolepsy. Excessive daytime sleepiness and cataplexy can result in serious injury or death if not treated. Individuals with untreated narcolepsy symptoms are involved in automobile accidents roughly 10 times more frequently than the general population. Among those receiving appropriate treatment, the accident rate is normal.[27,28]

Patient support groups are also useful for patients with narcolepsy and their family members. Social isolation can occur because of symptoms. Patients with narcolepsy can be stigmatized as being lazy and unproductive because of lack of understanding about this disorder.

CIRCADIAN RHYTHM DISORDERS

Circadian rhythm disorders can occur when the circadian time-keeping system loses synchrony with the environment. Lack of synchrony between the circadian time-keeping system and the environment disrupts the sleep-wake cycle and affects the patient's ability to have quality sleep. The two common symptoms are insomnia and excessive sleepiness. *Jet lag disorder* and *shift work sleep disorder* (see Special Sleep Needs of Nurses section on p. 110) are the most common types of circadian rhythm disorders.[29]

Jet lag disorder occurs when a person travels across multiple time zones. One's body time is not synchronized with environmental time. Most individuals crossing at least three time zones experience jet lag. The number of time zones crossed affects the severity of symptoms and the time it takes to recover. Resynchronization of the body's clock occurs at a rate of about 1 hr/day when traveling eastward and 1.5 hr/day when traveling westward. Melatonin is effective as a sleep aid to help synchronize the body's rhythm. Exposure to daylight assists synchronization of the body clock to environmental time.

Several strategies may help to reduce the risk of developing jet lag. Before travel the individual can start to get in harmony with the time schedule of the destination. When time at destination is brief (i.e., 2 days or less), keeping home-based sleep hours rather than adopting destination sleep hours may reduce sleepiness and jet lag symptoms.

SLEEP-DISORDERED BREATHING

The term **sleep-disordered breathing (SDB)** indicates abnormal respiratory patterns associated with sleep.[30] These include snoring, apnea, and hypopnea with increased respiratory effort leading to frequent arousals. SDB results in frequent sleep disruptions and alterations in sleep architecture. Obstructive sleep apnea is the most commonly diagnosed SDB problem.[31]

Obstructive Sleep Apnea

Obstructive sleep apnea (OSA), also called *obstructive sleep apnea–hypopnea syndrome* (OSAHS), is characterized by partial or complete upper airway obstruction during sleep. *Apnea* is the cessation of spontaneous respirations lasting longer than 10 seconds. *Hypopnea* is a condition characterized by shallow respirations (30% to 50% reduction in airflow). Airflow obstruction occurs because (1) narrowing of the air passages with relaxation of muscle tone during sleep leads to apnea and hypopnea or (2) the tongue and the soft palate fall backward and partially or completely obstruct the pharynx (Fig. 8-4).

Each obstruction may last from 10 to 90 seconds. During the apneic period the patient can experience *hypoxemia* (decreased PaO_2 or SpO_2) and *hypercapnia* (increased $PaCO_2$). These changes are ventilatory stimulants and cause brief arousals, but the patient may not fully awaken. The patient has a generalized startle response, snorts, and gasps, which cause the tongue and soft palate to move forward and the airway to open. Apnea and arousal cycles occur repeatedly, as many as 200 to 400 times during 6 to 8 hours of sleep.

Sleep apnea occurs in 2% to 10% of Americans but is considered to be underreported. The risk increases with obesity

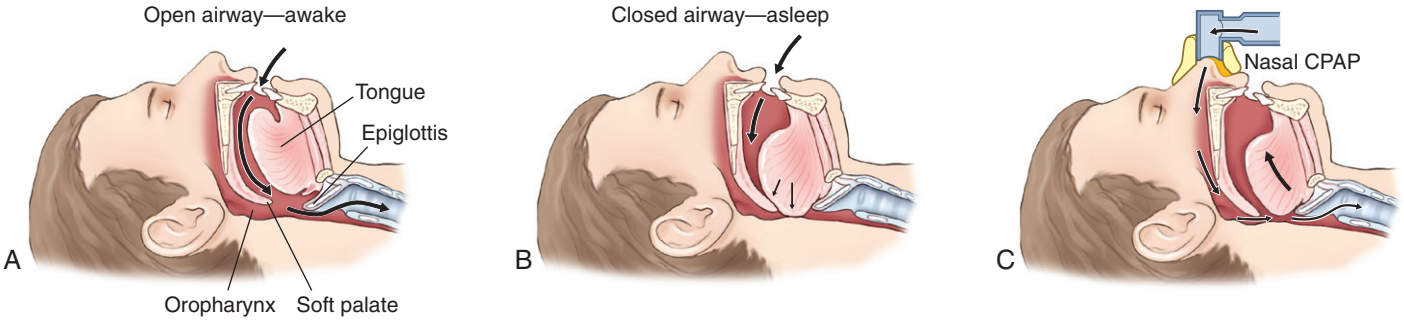

FIG. 8-4 How sleep apnea occurs. **A,** The patient predisposed to obstructive sleep apnea (OSA) has a small pharyngeal airway. **B,** During sleep, the pharyngeal muscles relax, allowing the airway to close. Lack of airflow results in repeated apneic episodes. **C,** Continuous positive airway pressure *(CPAP)* splints the airway open, preventing airflow obstruction.

INFORMATICS IN PRACTICE

Sleep Apnea Diagnosis and Monitoring

- Home respiratory monitoring is a cost-effective alternative for diagnosing sleep-related breathing disorders that allows patients the convenience of sleeping in their own home.
- Home respiratory monitoring is used as part of a comprehensive sleep evaluation and in patients likely to have moderate to severe obstructive sleep apnea but without heart failure, obstructive lung disease, or neuromuscular disease.
- Home respiratory monitoring is used to monitor the effectiveness of non-CPAP therapies for patients with sleep-related breathing disorders.
- Wireless monitors can detect changes in vital signs and pulse oximetry, raising an alarm if values fall outside of set parameters.
- Your patient may benefit from telehealth to diagnose and monitor for sleep apnea in the home.

CPAP, Continuous positive airway pressure.

(BMI greater than 28 kg/m^2), age greater than 65 years, neck circumference greater than 17 inches, craniofacial abnormalities that affect the upper airway, and acromegaly.[12,31] Smokers are more likely to have OSA. OSA is more common in men than in women until after menopause, when the prevalence of the disorder is equal.[13] Women with OSA have higher mortality rates than men with OSA. OSA patients with excessive daytime sleepiness have increased mortality.[31] Hypoxemia associated with OSA is greater in those patients with chronic obstructive pulmonary disease (COPD).[32]

Clinical Manifestations and Diagnostic Studies. Clinical manifestations of sleep apnea include frequent arousals during sleep, insomnia, excessive daytime sleepiness, and witnessed apneic episodes. The patient's bed partner may complain about the patient's loud snoring. Other symptoms include morning headaches (from hypercapnia or increased blood pressure that causes vasodilation of cerebral blood vessels), personality changes, and irritability.

Complications that can result from untreated sleep apnea include hypertension, right-sided heart failure from pulmonary hypertension caused by chronic nocturnal hypoxemia, and cardiac dysrhythmias. Chronic sleep loss predisposes the person to diminished ability to concentrate, impaired memory, failure to accomplish daily tasks, and interpersonal difficulties. The male patient may experience impotence. Driving accidents are more common in habitually sleepy people. Family life and the patient's ability to maintain employment are often compromised. As a result, the patient may experience severe depression. Cessation of breathing reported by the bed partner is usually a source of great anxiety because of the fear that breathing may not resume.

Assessment of the patient with OSA includes a thorough sleep and medical history. Symptoms of OSA, including daytime sleepiness, snoring, and witnessed apnea, are obvious characteristics of the disorder. Less obvious symptoms may include cardiovascular manifestations, muscle pain, and mood changes. Patients with OSA frequently have co-morbidities, including a history of stroke and cardiovascular disease.

PSG is used to make the diagnosis of sleep apnea. The patient's chest and abdominal movement, oral and nasal airflow, SpO_2, ocular movement, and heart rate and rhythm are monitored. A diagnosis of sleep apnea requires documentation of apneic events (no airflow with respiratory effort) or hypopnea (airflow diminished 30% to 50% with respiratory effort) of at least 10 seconds' duration. OSA is defined as more than five apnea/hypopnea events per hour accompanied by a 3% to 4% decrease in oxygen saturation. Severe apnea can be associated with apneic events of more than 30 to 50 per hour of sleep.[8]

Typically, PSG is done in a clinical sleep laboratory with technicians monitoring the patient. In some instances, portable sleep studies are conducted in the home setting. Overnight pulse oximetry assessment may be done to determine whether nocturnal oxygen supplementation is indicated.

NURSING AND COLLABORATIVE MANAGEMENT SLEEP APNEA

CONSERVATIVE TREATMENT

Mild sleep apnea (5 to 10 apnea/hypopnea events per hour) may respond to simple measures. Conservative treatment at home begins with sleeping on one's side rather than on the back. Elevating the head of the bed may eliminate OSA in some patients. Instruct the patient to avoid taking sedatives or consuming alcoholic beverages for 3 to 4 hours before sleep. Sleep medications often make OSA worse. OSA is a potentially life-threatening disorder. Because excessive weight worsens sleep apnea, referral to a weight loss program may be indicated. Weight loss and bariatric surgery reduce OSA.[33] Instruct the patient on the dangers of driving or using heavy equipment.

Symptoms may resolve in up to half of patients with OSA who use a special mouth guard, also called an oral appliance, during sleep to prevent airflow obstruction. Oral appliances bring the mandible and tongue forward to enlarge the airway

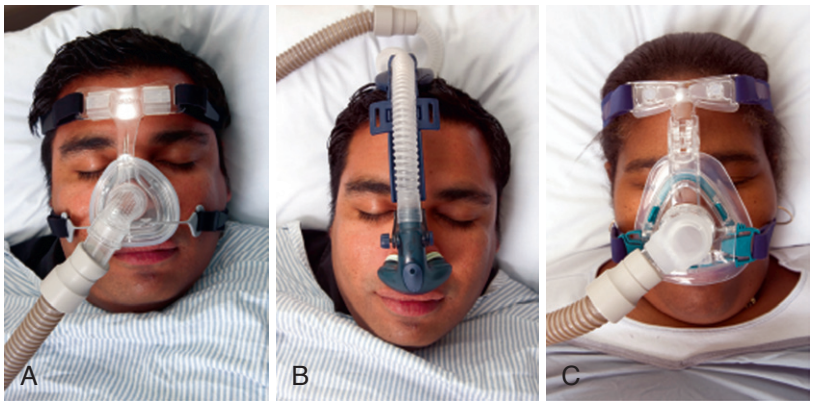

FIG. 8-5 Examples of positive airwave pressure devices for sleep apnea. **A,** Patient wearing a nasal mask and headgear (positive pressure only through nose). **B,** Patient wearing nasal pillows (positive pressure only through nose). **C**, Patient wearing a full face mask (positive pressure to both nose and mouth).

space, thereby preventing airway occlusion.[34] Some individuals find a support group beneficial, where they can express concerns and feelings and discuss strategies for resolving problems.

In patients with more severe symptoms (more than 15 apnea/hypopnea events per hour), continuous positive airway pressure (CPAP) by mask is the treatment of choice. With CPAP, the patient applies a nasal mask that is attached to a high-flow blower (Fig. 8-5). The blower is adjusted to maintain sufficient positive pressure (5 to 25 cm H_2O) in the airway during inspiration and expiration to prevent airway collapse. Some patients cannot adjust to wearing a mask over the nose or mouth or to exhaling against the high pressure. A technologically more sophisticated therapy, bilevel positive airway pressure (BiPAP), can deliver a higher inspiration pressure and a lower pressure during expiration. With BiPAP, the apnea can be relieved with a lower mean pressure and may be better tolerated.

CPAP reduces apnea episodes, daytime sleepiness, and fatigue. It improves quality of life ratings and returns cognitive functioning to normal.[35] Although CPAP is a highly effective treatment, compliance and adherence are poor. Approximately two thirds of patients using CPAP report side effects such as nasal stuffiness. First assess the patient's knowledge about OSA and CPAP, and involve the bed partner in teaching. Evaluate the patient for nasal resistance. Patient-centered selection of mask and device and exposure to CPAP before initiation of therapy are associated with successful adherence to CPAP treatment.[33] If necessary, facilitate referral for evaluation of equipment. For anxiety related to CPAP, the patient may be referred to a psychologist for desensitization therapy.

When patients with a history of OSA are hospitalized, be aware that the administration of opioid analgesics and sedating medications (benzodiazepines, barbiturates, hypnotics) may worsen OSA symptoms by depressing respiration. This will necessitate that the patient wear the CPAP or BiPAP when resting or sleeping. Many patients are able to use their own CPAP equipment, but hospital policy should be checked to be certain it can be used.

SURGICAL TREATMENT

If other measures fail, sleep apnea can be managed surgically. The two most common procedures are uvulopalatopharyngoplasty (UPPP or UP3) and genioglossal advancement and hyoid myotomy (GAHM). UPPP involves excision of the tonsillar pillars, uvula, and posterior soft palate to remove the obstructing tissue.[34] GAHM involves advancing the attachment of the muscular part of the tongue on the mandible. When GAHM is performed, UPPP is generally performed as well. Depending on the site of the obstruction, symptoms are relieved in up to 80% of patients. Radiofrequency ablation (RFA) alone or in combination with other surgical techniques is also used. RFA is the least invasive surgical intervention.[34]

Complications of airway obstruction or hemorrhage occur most often in the immediate postoperative period. Patients can usually be discharged home within 1 day after the procedure. Before going home the patient is taught what to expect during the postoperative recovery period. Tell patients that their throat will be sore. They may have a foul breath odor that may be reduced by rinsing with diluted mouthwash and then salt water after several days. Snoring may persist until the inflammation has subsided. Follow-up of patients after surgery is important. A repeat PSG is performed 3 to 4 months after surgery.

PERIODIC LIMB MOVEMENT DISORDER

Periodic limb movement disorder (PLMD) is characterized by involuntary, continual movement of the legs and/or arms that affects people only during sleep. PLMD rarely involves the arms. Sometimes abdominal, oral, and nasal movement accompanies PLMD. Movements typically occur for 0.5 to 10 seconds, in intervals separated by 5 to 90 seconds. PLMD causes poor-quality sleep, which may lead to excessive daytime sleepiness. PLMD occurs in 80% to 90% of individuals with restless legs syndrome (RLS).[36] (RLS is a disorder that is discussed in Chapter 59.)

PLMD is diagnosed using a detailed history from the patient and/or bed partner and doing a PSG. PLMD is treated by medications aimed at reducing or eliminating the limb movements or the arousals. Dopamine agonists (pramipexole [Mirapex] and ropinirole [Requip]) are preferred.

GERONTOLOGIC CONSIDERATIONS

SLEEP

With aging, the most notable changes are a decrease in the amount of deep sleep and an increase in arousals and awakenings. Older adults report greater problems getting to and main-

FIG. 8-6 Many older people have sleep problems. (Photodisc/Thinkstock)

taining sleep as compared with younger adults (Fig. 8-6). Older age is associated with overall shorter total sleep time, decreased sleep efficiency, and more awakenings.[37]

A common misconception is that older people need less sleep than younger people. In fact, the amount of sleep needed as a person ages remains relatively constant.[38]

Healthy older adults who do not complain of sleep disturbance often have fragmented sleep, nocturnal wakefulness, and reduced sleep efficiency when studied with PSG. Because older adults may attribute their disturbed sleep to normal aging, they may fail to report symptoms of sleep disorders to their health care providers.[37] Use a sleeping assessment (see Table 8-6) to detect sleep disturbances in older adults.

Multiple factors impair older adults' ability to obtain quality sleep. Insomnia symptoms in older adults frequently occur with depression, heart disease, body pain, and cognitive problems. Insomnia may have detrimental effects on cognitive function in healthy older adults. Older women report more trouble falling asleep and, especially, staying asleep. Other sleep disorders (e.g., sleep-disordered breathing) also increase with age and may manifest with insomnia symptoms.[37,38]

Awakening and getting out of bed during the night (e.g., to use the bathroom) increase the risk for falls. Older adults may use OTC medications or alcohol as a sleep aid. This practice can further increase the risk of falls at night. Chronic disturbed sleep in older adults can result in disorientation, delirium, impaired intellect, disturbed cognition, and increased risk of accidents and injury.[38]

Chronic conditions that are more common in older adults (COPD, diabetes, dementia, chronic pain, cancer) can affect sleep quality.[38] Medications used to treat these conditions can contribute to sleep problems. OTC medications also can lead to sleep disturbance. Cough and cold medications, especially those containing pseudoephedrine; caffeine-containing drugs; and drugs containing nicotine (e.g., nicotine gum, transdermal patches), are stimulants. Diphenhydramine, alone or in combination with other drugs, is sedating with anticholinergic effects. Any OTC medication labeled "PM" probably has diphenhydramine and should be used cautiously by older adults.[39]

Metabolism of most hypnotic drugs decreases with aging. Older adults have increased sensitivity to hypnotic and sedative medications. Thus drug therapies for sleep disturbances are started at lower doses and monitored carefully. Whenever possible, long-acting benzodiazepines should be avoided. Older adults receiving benzodiazepines are at increased risk of daytime sedation, falls, and cognitive and psychomotor impairment.

PARASOMNIAS

Parasomnias are unusual and often undesirable behaviors that occur while falling asleep, transitioning between sleep stages, or arousing from sleep. They are due to CNS activation and often involve complex behaviors. The parasomnia is generally goal directed, although the person is not aware or conscious of the act. Parasomnias may result in fragmented sleep and fatigue.

Sleepwalking and sleep terrors are arousal parasomnias that occur during NREM sleep. *Sleepwalking* behaviors can range from sitting up in bed, moving objects, and walking around the room to driving a car. During a sleepwalking event the individual may not speak and may have limited or no awareness of the event. On awakening, the individual does not remember the event. In the ICU a parasomnia may be misinterpreted as ICU psychosis. Sedated ICU patients can exhibit manifestations of a parasomnia.

Sleep terrors (night terrors) are characterized by a sudden awakening from sleep along with a loud cry and signs of panic. The person has marked increases in heart rate and respiration and diaphoresis. Factors in the ICU such as sleep disruption and deprivation, fever, stress, and exposure to noise and light can contribute to sleep terrors.

Nightmares are a parasomnia characterized by recurrent awakening with recall of a frightful or disturbing dream. These normally occur during the final third of sleep and in association with REM sleep. In critically ill patients nightmares are common and are most likely due to medications. Drug classes most likely to cause nightmares are sedative-hypnotics, β-adrenergic antagonists, dopamine agonists, and amphetamines.

SPECIAL SLEEP NEEDS OF NURSES

Nursing is one of several professions that necessitates night shift and rotating shift schedules. In many settings, nurses are asked to or volunteer to work a variety of day and night shifts, often alternating and rotating them. Unfortunately, nurses who do shift work often report less job satisfaction and more job-related stress. A large number of nurses who work the night shift report episodes of nodding off while driving home after work.[40]

Nurses on permanent night or rapidly rotating shifts are at increased risk of experiencing *shift work sleep disorder,* characterized by insomnia, sleepiness, and fatigue. Nurses on rotating shifts get the least amount of sleep. With repeated periods of inadequate sleep, the sleep debt grows. Poor sleep is the strongest predictor of chronic fatigue in nurses doing shift work. As a result, rotating and night shift schedules pose challenges for the individual nurse's health and patient safety.[40]

Shift work alters the synchrony between circadian rhythms and the environment, leading to sleep disruption. Nurses working the night shift are often too sleepy to be fully alert at work and too alert to sleep soundly the next day. Sustained alterations in circadian rhythms such as those imposed by rotating shift work have been linked to increased morbidity and mortality risks associated with cardiovascular problems. In

addition, mood disorders such as anxiety are higher in nurses who work rotating shifts.

From a safety perspective, disturbed sleep and subsequent fatigue can result in errors and accidents for nurses as well as for their patients.[41] Fatigue diminishes or distorts perceptual skills, judgment, and decision-making capabilities. Lack of sleep reduces the ability to cope and handle stress and may result in physical, mental, and emotional exhaustion.

The problem of sleep disruption is critically important to nursing. Several strategies may help reduce the distress associated with rotating shift work. These include brief periods of on-site napping. Maintaining a consistent sleep-wake schedule even on days off is optimum but perhaps unrealistic. For night shift work, scheduling the sleep period just before going to work increases alertness and vigilance, improves reaction times, and decreases accidents during night shift work. Nurses who have control over their work schedules appear to experience less sleep disruption than those whose schedule is imposed. As a nurse, you need to manage the impact of sleep disruption through the use of sleep hygiene practices.

CASE STUDY

Insomnia

iStockphoto/Thinkstock

Patient Profile

G.P., a 49-year-old African American woman, is seen in the primary care clinic for complaints of chronic fatigue. She is postmenopausal based on self-report. In the past year, since the end of her periods, she has experienced daily hot flashes and sleep problems. She denies any other health problems. On a usual workday she drinks two cups of hot tea in the morning and one can of diet cola in the late afternoon. Currently she is taking OTC diphenhydramine for sleep. Her partner, who has accompanied her to the clinic, states that her snoring has gotten worse and it is interfering with his sleep.

Subjective Data

- Complains of hot flashes and nighttime sweating
- Complains of daytime tiredness and fatigue
- States she has trouble getting to sleep and staying asleep

Objective Data

Physical Examination

- Laboratory evaluations within normal limits
- Overweight (20% over ideal body weight for height)
- BP 155/92 mm Hg

Diagnostic Studies

- Nighttime polysomnography study reveals episodes of obstructive sleep apnea

Collaborative Care

- CPAP nightly
- Referred for weight reduction counseling
- Follow-up to rule out other potential sleep disturbances

Discussion Questions

1. What are G.P.'s risk factors for sleep apnea?
2. What specific sleep hygiene practices could G.P. use to improve the quality of her sleep?
3. How does CPAP work?
4. Based on the data above, what are the major health risks for G.P. from sleep apnea?
5. ***Priority Decision:*** What are the priority nursing interventions for G.P.? What collaborative care treatment ought to be added to the treatment plan?
6. ***Delegation Decision:*** For the interventions that you identified in the above question, which of the following personnel could be responsible for implementing them: RN, LPN, UAP?
7. ***Priority Decision:*** Based on the assessment data provided, what are the priority nursing diagnoses? Are there any collaborative problems?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg.*

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Sleep is best described as a
   - **a.** loosely organized state similar to coma.
   - **b.** state in which pain sensitivity decreases.
   - **c.** quiet state in which there is little brain activity.
   - **d.** state in which an individual lacks conscious awareness of the environment.
2. Which statement is true regarding rapid eye movement (REM) sleep?
   - **a.** The EEG pattern is quiescent.
   - **b.** It occurs only once in the night.
   - **c.** It is separated by distinct physiologic stages.
   - **d.** The most vivid dreaming occurs during this phase.
3. Insufficient sleep is associated with *(select all that apply)*
   - **a.** increased body mass index.
   - **b.** increased insulin resistance.
   - **c.** impaired cognitive functioning.
   - **d.** increased immune responsiveness.
   - **e.** increased daytime body temperature.
4. When teaching the patient with primary insomnia about sleep hygiene, the nurse should emphasize
   - **a.** the importance of daytime naps.
   - **b.** the need to exercise before bedtime.
   - **c.** the need for long-term use of hypnotics.
   - **d.** avoiding caffeine-containing beverages 6 to 9 hours before bedtime.
5. While caring for a patient with a history of narcolepsy with cataplexy, the nurse can delegate which activity to the unlicensed assistive personnel (UAP)?
   - **a.** Teaching about the timing of medications
   - **b.** Walking the patient to and from the bathroom
   - **c.** Developing a plan of care with a family member
   - **d.** Planning an appropriate diet that avoids caffeine-containing foods

6. A patient with sleep apnea would like to avoid using a nasal CPAP device if possible. To help him reach this goal, the nurse suggests that the patient
   a. lose excess weight.
   b. take a nap during the day.
   c. eat a high-protein snack at bedtime.
   d. use mild sedatives or alcohol at bedtime.
7. A patient on the surgical unit has a history of parasomnia (sleepwalking). What statement describes parasomnia?
   a. Hypnotic medications reduce the risk of sleepwalking.
   b. The patient is often unaware of the activity on awakening.
   c. The patient should be restrained at night to prevent personal harm.
   d. The potential for sleepwalking is reduced by exercise before sleep.
8. Strategies to reduce sleepiness during nighttime working include
   a. exercising before work.
   b. taking melatonin before working the night shift.
   c. sleeping for at least 2 hours immediately before work time.
   d. walking for 10 minutes every 4 hours during the night shift.

1. d, 2. d, 3. a, b, c, 4. d, 5. b, 6. a, 7. b, 8. c.

LEARNING OUTCOMES

1. Define pain.
2. Describe the neural mechanisms of pain and pain modulation.
3. Differentiate between nociceptive and neuropathic types of pain.
4. Explain the physical and psychologic effects of unrelieved pain.
5. Interpret the subjective and objective data that are obtained from a comprehensive pain assessment.
6. Describe effective interdisciplinary pain management techniques.
7. Describe drug and nondrug methods of pain relief.
8. Explain your role and responsibility in pain management.
9. Discuss ethical and legal issues related to pain and pain management.
10. Evaluate the influence of one's own knowledge, beliefs, and attitudes about pain assessment and management.

Pain is a complex, multidimensional experience that can cause suffering and decreased quality of life. Pain is one of the major reasons that people seek health care. To effectively assess and manage patients with pain, you need to understand the physiologic and psychosocial dimensions of pain. This chapter presents evidence-based information to help you assess and manage pain successfully in collaboration with other health care providers.

MAGNITUDE OF PAIN PROBLEM

Every year, millions of people suffer from pain. Annually in the United States, at least 25 million people experience acute pain as a result of injury or surgery.[1] Common chronic pain conditions such as arthritis, migraine headache, and back pain affect approximately 116 million American adults.[2] Seventy percent of all cancer patients experience significant pain during their illness.[3] The financial impact of pain is staggering. In the United States, unrelieved pain and inadequate management of pain costs an estimated $560 billion to $635 billion each year in direct medical treatment costs and lost work productivity.[2]

Despite the high prevalence and costs of acute and chronic pain, inadequate pain management occurs. For example, approximately a third of patients enrolled in hospice reported pain at their last hospice visit.[4] Cancer pain is often undertreated.[5]

Consequences of untreated pain include unnecessary suffering, physical and psychosocial dysfunction, immunosup-

pression, and sleep disturbances[2] (Table 9-1). The varied reasons for the undertreatment of pain are discussed in this chapter.

DEFINITIONS AND DIMENSIONS OF PAIN

In 1968 Margo McCaffery, a nurse and pioneer in pain management, defined **pain** as "whatever the person experiencing the pain says it is, existing whenever the person says it does."[6] The International Association for the Study of Pain (IASP) defines *pain* as "an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage."[2]

Note that these definitions emphasize the subjective nature of pain, in which the patient's self-report is the most valid means of assessment. Although understanding the patient's experience and relying on his or her self-report is essential, this view is problematic for many patients. For example, patients who are comatose or who suffer from dementia, patients who are mentally disabled, and patients with expressive aphasia possess varying abilities to report pain. In these instances, you must incorporate nonverbal information such as behaviors into your pain assessment.

TABLE 9-2 DIMENSIONS OF PAIN

Dimension	Description
Physiologic	• Genetic, anatomic, and physical determinants of pain influence how painful stimuli are processed, recognized, and described.
Affective	• Emotional responses to pain include anger, fear, depression, and anxiety. • Negative emotions impair patient's quality of life.
Cognitive	• Beliefs, attitudes, memories, and meaning attributed to pain influence the ways in which a person responds to pain.
Behavioral	• Observable actions (e.g., grimacing, irritability) are used to express or control pain. • People unable to communicate may have behavioral changes (e.g., agitation, combativeness).
Sociocultural	• Age and gender influence nociceptive processes and responses to opioids. • Families and caregivers influence patient's response to pain through their beliefs, behaviors, and support. • Culture affects pain expression, medication use, and pain-related beliefs and coping methods.

GENDER DIFFERENCES

Pain

Men
- Men are less likely to report pain than women.
- Men report more control over pain.
- Men are less likely than women to use alternative treatments for pain.

Women
- Women experience more chronic pain than men.
- Even when they have the same condition as men, women have higher levels of pain. Women more frequently experience migraine headache, back pain, arthritis, fibromyalgia, irritable bowel syndrome, neuropathic pain, abdominal pain, and foot ache.
- Women are more likely to be diagnosed with a nonspecific, somatic diagnosis and less likely to receive analgesics for symptoms of chest and abdominal pain.

With pain defined as a human experience, successful pain assessment and treatment must incorporate multiple dimensions.[7] The biopsychosocial model of pain includes the physiologic, affective, cognitive, behavioral, and sociocultural dimensions of pain (Table 9-2).

The emotional distress of pain can cause *suffering*, which is the state of distress associated with loss. Suffering can result in a profound sense of insecurity and lack of control. When suffering occurs, people can experience spiritual distress. Achieving pain relief is an essential step in relieving suffering. In addition, the assessment of ways in which a person's spirituality influences and is influenced by pain is important.[8]

The meaning of the pain can be critical. For example, a woman in labor may experience severe pain but can manage it without analgesics because for her it is associated with a joyful event. Moreover, she may feel control over her pain because of

the training she received in prenatal classes and the knowledge that the pain is time-limited. In contrast, a woman with chronic, undefined musculoskeletal pain may be plagued by thoughts that her pain is "not real," is uncontrollable, or is caused by her own actions. These perceptions will influence the ways in which a person responds to pain and must be incorporated into a comprehensive treatment plan.

Some people cope with pain by distracting themselves, whereas others convince themselves that the pain is permanent, untreatable, and overwhelming. People who believe that their pain is uncontrollable and overwhelming are more likely to have poor outcomes.[9]

Families and caregivers influence the patient's response to pain through their beliefs and behaviors. For example, families may discourage the patient from taking opioids because they fear the patient will become addicted.

Pain Mechanisms

Nociception is the physiologic process by which information about tissue damage is communicated to the central nervous system (CNS). It involves four processes: (1) transduction, (2) transmission, (3) perception, and (4) modulation (Fig. 9-1).

Transduction. **Transduction** involves the conversion of a noxious mechanical, thermal, or chemical stimulus into an electrical signal called an action potential. Noxious (tissue-damaging) stimuli, including thermal (e.g., sunburn), mechanical (e.g., surgical incision), or chemical (e.g., toxic substances) stimuli, cause the release of numerous chemicals such as hydrogen ions, substance P, and adenosine triphosphate (ATP) into the damaged tissues. Other chemicals are released from mast cells (e.g., serotonin, histamine, bradykinin, prostaglandins) and macrophages (e.g., interleukins, tumor necrosis factor [TNF]). These chemicals activate nociceptors, which are specialized receptors, or free nerve endings, that respond to painful stimuli. Activation of nociceptors results in an action potential that is carried from the nociceptors to the spinal cord primarily via small, rapidly conducting, myelinated A-delta fibers and slowly conducting unmyelinated C fibers.

In addition to stimulating nociceptors to fire, inflammation and the subsequent release of chemical mediators lower nociceptor thresholds. As a result, nociceptors may fire in response to stimuli that previously were insufficient to elicit a response. They may also fire in response to non-noxious stimuli, such as light touch. This increased susceptibility to nociceptor activation is called *peripheral sensitization.* Leukotrienes, prostaglandins, cytokines, and substance P are involved in peripheral sensitization. Cyclooxygenase (COX), an enzyme produced in the inflammatory response, also plays an important role in peripheral sensitization. A clinical example of this process is sunburn. This thermal injury causes inflammation that results in a sensation of pain when the affected skin is lightly touched. Peripheral sensitization also amplifies signal transmission, which in turn contributes to central sensitization (discussed under Dorsal Horn Processing). The pain produced from activation of peripheral nociceptors is called *nociceptive pain* (described later in the chapter on p. 119).

Therapies that alter either the local environment or sensitivity of the peripheral nociceptors can prevent transduction and initiation of an action potential. Decreasing the effects of chemicals released at the periphery is the basis of several drug approaches to pain relief. For example, nonsteroidal antiinflammatory drugs (NSAIDs), such as ibuprofen (Advil, Motrin) and naproxen (Naprosyn, Aleve), and corticosteroids, such as dexamethasone (Decadron), exert their analgesic effects by blocking pain-sensitizing chemicals. NSAIDs block the action of COX, thereby interfering with the production of prostaglandins. Corticosteroids reduce the production of both prostaglandins and leukotrienes (see Fig. 12-2).

Drugs that stabilize the neuronal membrane and inactivate peripheral sodium channels inhibit production of the nerve impulse. These medications include local anesthetics (e.g., injectable or topical lidocaine, bupivacaine [Sensorcaine], and

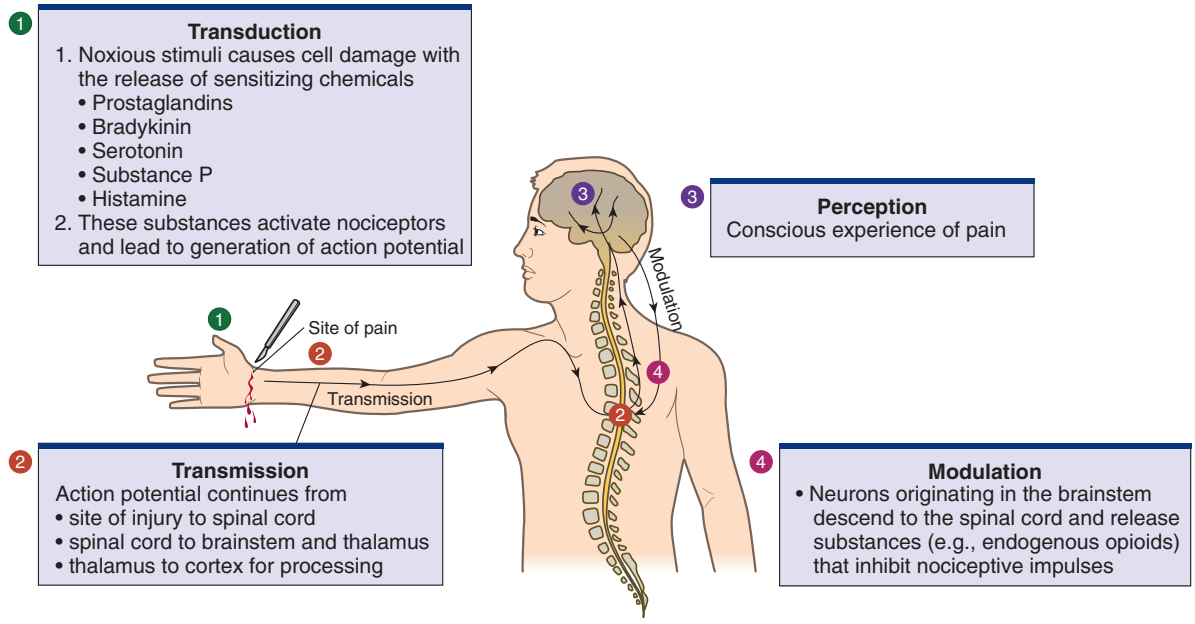

FIG. 9-1 Nociceptive pain originates when the tissue is injured. *1,* Transduction occurs when there is release of chemical mediators. *2,* Transmission involves the conduct of the action potential from the periphery (injury site) to the spinal cord and then to the brainstem, thalamus, and cerebral cortex. *3,* Perception is the conscious awareness of pain. *4,* Modulation involves signals from the brain going back down the spinal cord to modify incoming impulses.

ropivacaine [Naropin]) and antiseizure drugs (e.g., carbamazepine [Tegretol] and lamotrigine [Lamictal]).

Transmission. **Transmission** is the process by which pain signals are relayed from the periphery to the spinal cord and then to the brain. The nerves that carry pain impulses from the periphery to the spinal cord are called primary afferent fibers. These include A-delta and C fibers, each of which is responsible for a different pain sensation. As previously mentioned, A-delta fibers are small, myelinated fibers that conduct pain rapidly and are responsible for the initial, sharp pain that accompanies tissue injury. C fibers are small, unmyelinated fibers that transmit painful stimuli more slowly and produce pain that is typically aching or throbbing in quality. Primary afferent fibers terminate in the dorsal horn of the spinal cord. Activity in the dorsal horn integrates and modulates pain inputs from the periphery.

The propagation of pain impulses from the site of transduction to the brain is shown in Fig. 9-1. Three segments are involved in nociceptive signal transmission: (1) transmission along the peripheral nerve fibers to the spinal cord, (2) dorsal horn processing, and (3) transmission to the thalamus and the cerebral cortex.

Transmission to Spinal Cord. The first-order neuron extends the entire distance from the periphery to the dorsal horn of the spinal cord with no synapses. For example, an afferent fiber from the great toe travels from the toe through the fifth lumbar nerve root into the spinal cord; it is one cell. Once generated, an action potential travels all the way to the spinal cord unless it is blocked by a sodium channel inhibitor (e.g., local anesthetic) or disrupted by a lesion such as a dorsal root entry zone lesion.

The manner in which nerve fibers enter the spinal cord is central to the notion of spinal dermatomes. *Dermatomes* are areas on the skin that are innervated primarily by a single spinal cord segment. The distinctive pattern of the rash caused by herpes zoster (shingles) across the back and trunk is determined by dermatomes (see Fig. 24-7). Different dermatomes and their innervations are illustrated in eFig. 9-1 (available on the website for this chapter) and Fig. 56-6.

Dorsal Horn Processing. Once a nociceptive signal arrives in the spinal cord, it is processed within the dorsal horn. Neurotransmitters released from the afferent fiber bind to receptors on nearby cell bodies and dendrites of cells. Some of these neurotransmitters (e.g., glutamate, aspartate, substance P) produce activation, whereas others (e.g., γ-aminobutyric acid [GABA], serotonin, norepinephrine) inhibit activation of nearby cells. In this area, exogenous and endogenous opioids also play an important role by binding to opioid receptors and blocking the release of neurotransmitters, particularly substance P. Endogenous opioids include enkephalin and β-endorphin. They are capable of producing analgesic effects similar to those of exogenous opioids such as morphine.

Increased sensitivity and hyperexcitability of neurons in the CNS is called *central sensitization.* Peripheral tissue damage or nerve injury can cause central sensitization, and continued nociceptive input from the periphery is necessary to maintain it. As a result of the increased excitability of neurons within the CNS, normal sensory inputs cause abnormal sensing and responses to painful and other stimuli. This explains why some people experience significant pain from touch or tactile stimulation in and around the areas of tissue or nerve injury. This is called *allodynia*. With central sensitization, the central processing circuits are altered. In some cases, central sensitization can be long-lasting due to changes in the synapse.[10]

With ongoing stimulation of slowly conducting unmyelinated C-fiber nociceptors, firing of specialized dorsal horn neurons gradually increases. These inputs create many problems, including the sprouting of wide dynamic range (WDR) neurons and induction of glutamate-dependent *N*-methyl-D-aspartate (NMDA) receptors. WDR neurons respond to both nociceptive and non-nociceptive inputs that are of varying levels of stimulus intensity. When these neuron dendrites sprout, they grow into areas where pain-receiving nerve cell bodies are located. This results in the capacity to transmit a broader range of stimuli-producing signals, which are then passed up the spinal cord and brain. This process is known as *windup* and depends on the activation of NMDA receptors. NMDA receptor antagonists, such as ketamine (Ketalar), potentially interrupt or block mechanisms that lead to or sustain central sensitization. Windup, like central sensitization and hyperalgesia (increased pain responses to noxious stimuli), is induced by C-fiber inputs. Windup is different, however, in that it can be short lasting, whereas central sensitization and hyperalgesia persist over time.[11]

It is important for you to understand that acute, unrelieved pain leads to chronic pain through the process of central sensitization. Acute tissue injury produces a cascade of events that involve the release of certain excitatory neurotransmitters (e.g., glutamate) and neuropsychologic responses. Even brief intervals of acute pain are capable of inducing long-term neuronal remodeling and sensitization *(plasticity),* chronic pain, and lasting psychologic distress.

Neuroplasticity refers to processes that allow neurons in the brain to compensate for injury and adjust their responses to new situations or changes in their environment.[12] Neuroplasticity contributes to adaptive mechanisms for reducing pain but also can result in maladaptive mechanisms that enhance pain. Genetic variability among individuals may have an important effect on the plasticity of the CNS.[12] Understanding this phenomenon helps explain individual differences in response to pain and why some patients develop chronic pain conditions whereas others do not. Clinically, central sensitization of the dorsal horn results in (1) hyperalgesia, (2) painful responses to normally innocuous stimuli (allodynia), (3) prolonged pain after the original noxious stimulus ends (called *persistent pain*), and (4) the extension of tenderness or increased pain sensitivity outside of an area of injury to include uninjured tissue (i.e., expansion of nociceptive receptive fields, or secondary hyperalgesia).[13]

Referred pain must be considered when interpreting the location of pain reported by the person with an injury or a disease involving visceral organs. The location of a stimulus may be distant from the pain location reported by the patient (Fig. 9-2). For example, pain from liver disease is frequently located in the right upper abdominal quadrant, but can also be referred to the anterior and posterior neck region and to a posterior flank area. If referred pain is not considered when evaluating a pain location report, diagnostic tests and therapy could be misdirected.

Transmission to Thalamus and Cortex. From the dorsal horn, nociceptive stimuli are communicated to the *third-order neuron,* primarily in the thalamus, and several other areas of the brain. Fibers of dorsal horn projection cells enter the brain through several pathways, including the spinothalamic tract and spinoreticular tract. Distinct thalamic nuclei receive nociceptive

input from the spinal cord and have projections to several regions in the cerebral cortex, where the perception of pain is presumed to occur.

Therapeutic approaches that target pain transmission include opioid analgesics that bind to opioid receptors on primary afferent and dorsal horn neurons. These agents mimic the inhibitory effects of endogenous opioids. Another medication, baclofen (Lioresal), inhibits transmission by binding to GABA receptors, thus mimicking the inhibitory effects of GABA.

Perception. *Perception* occurs when pain is recognized, defined, and assigned meaning by the individual experiencing the pain. In the brain, nociceptive input is perceived as pain. There is no single, precise location where pain perception occurs. Instead, pain perception involves several brain structures. For example, it is believed that the reticular activating system (RAS) is responsible for warning the individual to attend to the pain stimulus; the somatosensory system is responsible for localization and characterization of pain; and the limbic system is responsible for the emotional and behavioral responses to pain. Cortical structures also are crucial to constructing the meaning of the pain.

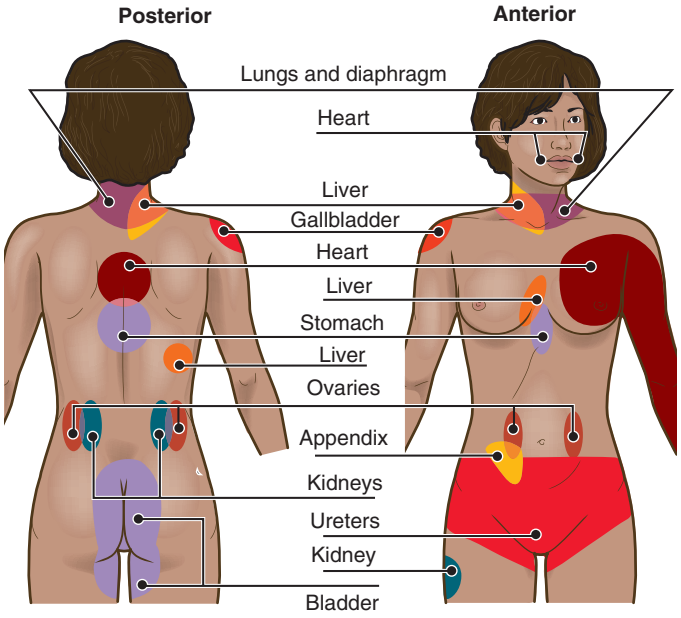

FIG. 9-2 Typical areas of referred pain.

Therefore behavioral strategies such as distraction and relaxation are effective pain-reducing therapies for many people. By directing attention away from the pain sensation, patients can reduce the sensory and affective components of pain. Opioids and other classes of analgesics such as some types of antiseizure drugs and antidepressants modify pain perception.

Modulation. **Modulation** involves the activation of descending pathways that exert inhibitory or facilitatory effects on the transmission of pain (see Fig. 9-1). Depending on the type and degree of modulation, nociceptive stimuli may or may not be perceived as pain. Modulation of pain signals can occur at the level of the periphery, spinal cord, brainstem, and cerebral cortex. Descending modulatory fibers release chemicals such as serotonin, norepinephrine, GABA, and endogenous opioids that can inhibit pain transmission.

Several antidepressants exert their effects through the modulatory systems. For example, tricyclic antidepressants (e.g., amitriptyline [Elavil]) and serotonin norepinephrine reuptake inhibitors (SNRIs) (e.g., venlafaxine [Effexor] and duloxetine [Cymbalta]) are used in the management of chronic nonmalignant and cancer pain. These agents interfere with the reuptake of serotonin and norepinephrine, thereby increasing their availability to inhibit noxious stimuli.

CLASSIFICATION OF PAIN

Pain can be categorized in several ways. Most commonly, pain is categorized as nociceptive or neuropathic based on underlying pathology (Table 9-3). Another useful scheme is to classify pain as acute or chronic (Table 9-4).

TABLE 9-3 COMPARISON OF NOCICEPTIVE AND NEUROPATHIC PAIN

	Nociceptive Pain	Neuropathic Pain*
Definition	Normal processing of stimulus that damages normal tissue or has the potential to do so if prolonged.	Abnormal processing of sensory input by the peripheral or central nervous system.
Treatment	Usually responsive to nonopioid and/or opioid drugs.	Treatment usually includes adjuvant analgesics.
Types	**Superficial Somatic Pain** Pain arising from skin, mucous membranes, subcutaneous tissue. Tends to be well localized. *Examples:* sunburn, skin contusions **Deep Somatic Pain** Pain arising from muscles, fasciae, bones, tendons. Localized or diffuse and radiating. *Examples:* arthritis, tendonitis, myofascial pain **Visceral Pain** Pain arising from visceral organs, such as the GI tract and bladder. Well or poorly localized. Often referred to cutaneous sites. *Examples:* appendicitis, pancreatitis, cancer affecting internal organs, irritable bowel and bladder syndromes	**Central Pain** Caused by primary lesion or dysfunction in the CNS. *Examples:* poststroke pain, pain associated with multiple sclerosis **Peripheral Neuropathies** Pain felt along the distribution of one or many peripheral nerves caused by damage to the nerve. *Examples:* diabetic neuropathy, alcohol-nutritional neuropathy, trigeminal neuralgia, postherpetic neuralgia **Deafferentation Pain** Pain resulting from a loss of afferent input. *Examples:* phantom limb pain, postmastectomy pain, spinal cord injury pain **Sympathetically Maintained Pain** Pain that persists secondary to sympathetic nervous system activity. *Examples:* phantom limb pain, complex regional pain syndrome

Adapted from National Institute of Neurological Disorders and Stroke: Complex regional pain syndrome fact sheet. Retrieved from *www.ninds.nih.gov/disorders/reflex_sympathetic_dystrophy/detail_reflex_sympathetic_dystrophy.htm.*

*Note: Some types of neuropathic pain (e.g., postherpetic neuralgia) are caused by more than one neuropathologic mechanism.

CNS, Central nervous system; *GI,* gastrointestinal.

Nociceptive Pain

Nociceptive pain is caused by damage to somatic or visceral tissue. *Somatic pain* often is further categorized as superficial or deep. *Superficial pain* arises from skin, mucous membranes, and subcutaneous tissues. It is often described as sharp, burning, or prickly. *Deep pain* is often characterized as deep, aching, or throbbing and originates in bone, joint, muscle, skin, or connective tissue.

Visceral pain comes from the activation of nociceptors in the internal organs and lining of the body cavities such as the thoracic and abdominal cavities. Visceral nociceptors respond to inflammation, stretching, and ischemia. Stretching of hollow viscera in the intestines and bladder that occurs from tumor involvement or obstruction can produce distention and intense cramping pain. Examples of visceral nociceptive pain include pain from a surgical incision, pancreatitis, and inflammatory bowel disease.

Neuropathic Pain

Neuropathic pain is caused by damage to peripheral nerves or structures in the CNS.[14] Typically described as numbing, hot, burning, shooting, stabbing, sharp, or electric shock–like, neuropathic pain can be sudden, intense, short lived, or lingering. Paroxysmal firing of injured nerves is responsible for shooting and electric shock–like sensations. Common causes of neuropathic pain include trauma, inflammation (e.g., secondary to a herniated disc inflaming the adjacent nerve and dorsal root ganglion), metabolic diseases (e.g., diabetes mellitus), alcoholism, infections of the nervous system (e.g., herpes zoster, human immunodeficiency virus), tumors, toxins, and neurologic diseases (e.g., multiple sclerosis).

Deafferentation pain results from loss of afferent input secondary to either peripheral nerve injury (e.g., amputation) or CNS damage, including a spinal cord injury. *Sympathetically maintained pain* is associated with dysregulation of the autonomic nervous system, and *central pain* is caused by CNS lesions or dysfunction. Painful peripheral polyneuropathies (pain felt along the distribution of multiple peripheral nerves) and painful mononeuropathies (pain felt along the distribution of a damaged nerve) arise from damage to peripheral nerves and generate pain that may be described as burning, paroxysmal, or shock-like. The patient may have associated positive or negative motor and sensory signs, including numbness, allodynia, or change in reflexes and motor strength. No single quality descriptor or sign or symptom is diagnostic for neuropathic pain. Examples of neuropathic pain include postherpetic neuralgia, phantom limb pain, diabetic neuropathies, and trigeminal neuralgia.

One particularly debilitating type of neuropathic pain is **complex regional pain syndrome (CRPS).** Typical features include dramatic changes in the color and temperature of the skin over the affected limb or body part, accompanied by intense burning pain, skin sensitivity, sweating, and swelling. CRPS type I is frequently triggered by tissue injury, surgery, or a vascular event such as stroke.[14] CRPS type II includes all these features in addition to a peripheral nerve lesion.

Neuropathic pain often is not well controlled by opioid analgesics alone. Treatment frequently necessitates a multimodal approach combining various adjuvant analgesics, including tricyclic antidepressants (e.g., nortriptyline [Pamelor], desipramine [Norpramin]), SNRIs (e.g., venlafaxine, duloxetine, bupropion [Wellbutrin, Zyban]), antiseizure drugs (e.g., gabapentin [Neurontin], pregabalin [Lyrica]), transdermal lidocaine, and α_2-adrenergic agonists (e.g., clonidine [Catapres]). NMDA receptor antagonists such as ketamine have shown promise in alleviating neuropathic pain refractory to other drugs.[14]

TABLE 9-4 DIFFERENCES BETWEEN ACUTE AND CHRONIC PAIN

	Acute Pain	Chronic Pain
Onset	Sudden.	Gradual or sudden.
Duration	<3 mo or as long as it takes for normal healing to occur.	>3 mo. May start as acute injury or event but continues past the normal time for recovery.
Severity	Mild to severe.	Mild to severe.
Cause of pain	Generally can identify a precipitating event (e.g., illness, surgery).	May not be known. Original cause of pain may differ from mechanisms that maintain the pain.
Course of pain	Decreases over time and goes away as recovery occurs.	Typically pain does not go away. Characterized by periods of increasing and decreasing pain.
Typical physical and behavioral manifestations	Manifestations vary but can reflect sympathetic nervous system activation: • ↑ Heart rate, respiratory rate, blood pressure • Diaphoresis, pallor • Anxiety, agitation, confusion • Urine retention	Predominantly behavioral manifestations: • Flat affect • ↓ Physical activity • Fatigue • Withdrawal from social interaction
Usual goals of treatment	Pain control with eventual elimination.	Pain control to the extent possible. Focus on enhancing function and quality of life.

Acute and Chronic Pain

Acute pain and chronic pain differ in their cause, course, manifestations, and treatment (see Table 9-4). Examples of *acute pain* include postoperative pain, labor pain, pain from trauma (e.g., lacerations, fractures, sprains), pain from infection (e.g., dysuria from cystitis), and pain from acute ischemia. For acute pain, treatment includes analgesics for symptom control and treatment of the underlying cause (e.g., splinting for a fracture, antibiotic therapy for an infection). Normally, acute pain diminishes over time as healing occurs. However, acute pain that persists can ultimately lead to disabling chronic pain states. For example, pain associated with herpes zoster (shingles) subsides as the acute infection resolves, usually within a month. However, sometimes the pain persists and develops into a chronic pain state called *postherpetic neuralgia.*

Chronic pain, or *persistent pain,* lasts for longer periods, often defined as longer than 3 months or past the time when an expected acute pain or acute injury should subside. The severity and functional impact of chronic pain often are disproportionate to objective findings because of changes in the nervous

TABLE 9-5 CORE PRINCIPLES OF PAIN ASSESSMENT

Principles	Nursing Implications
1. Patients have the right to appropriate assessment and management of pain.	• Assess pain in *all* patients.
2. Pain is always subjective.	• Patient's self-report of pain is the single most reliable indicator of pain. • Accept and respect this self-report unless there are clear reasons for doubt.
3. Physiologic and behavioral signs of pain (e.g., tachycardia, grimacing) are not reliable or specific for pain.	• Do not rely primarily on observations and objective signs of pain unless the patient is unable to self-report pain.
4. Pain is an unpleasant sensory and emotional experience.	• Address both physical and psychologic aspects of pain when assessing pain.
5. Assessment approaches, including tools, must be appropriate for the patient population.	• Special considerations are needed for assessing pain in patients with difficulty communicating. • Include family members in the assessment process (when appropriate).
6. Pain can exist even when no physical cause can be found.	• Do not attribute pain that does not have an identifiable cause to psychologic causes.
7. Different patients experience different levels of pain in response to comparable stimuli.	• A uniform pain threshold does not exist.
8. Patients with chronic pain may be more sensitive to pain and other stimuli.	• Pain tolerance varies among and within individuals depending on various factors (e.g., heredity, energy level, coping skills, prior experience with pain).
9. Unrelieved pain has adverse consequences. Acute pain that is not adequately controlled can result in physiologic changes that increase the likelihood of developing persistent pain.	• Encourage patients to report pain, especially patients who are reluctant to discuss pain, deny pain when it is probably present, or fail to follow through on prescribed treatments.

system not detectable with standard tests. Whereas acute pain functions as a signal, warning the person of potential or actual tissue damage, chronic pain does not appear to have an adaptive role. Chronic pain can be disabling and often is accompanied by anxiety and depression. As previously discussed, untreated acute pain leads to chronic pain through central sensitization and neuroplasticity. Consequently, it is imperative to treat acute pain aggressively and effectively to help prevent chronic pain.

PAIN ASSESSMENT

Assessment is an essential, though often overlooked, step in pain management. Regularly screen all patients for pain and, when present, perform a more thorough pain assessment. The key to accurate and effective pain assessment is to consider the core principles of pain assessment (Table 9-5).

The goals of a nursing pain assessment are to (1) describe the patient's pain experience in order to identify and implement appropriate pain management techniques and (2) identify the patient's goal for therapy and resources for self-management.

Elements of a Pain Assessment

Most components of a pain assessment involve direct interview or observation of the patient. Diagnostic studies and physical examination findings complete the initial assessment. Although the assessment differs according to the clinical setting, patient population, and point of care (i.e., whether the assessment is part of an initial workup or a reassessment of pain following therapy), the evaluation of pain should always be multidimensional (Table 9-6).

Before beginning any assessment, recognize that patients may use words other than "pain." For example, older adults may deny that they have pain but respond positively when asked if they have soreness or aching. Document the specific words that the patient uses to describe pain. Then consistently ask the patient about pain using those words.

Pain Pattern. Assessing pain *onset* involves determining when the pain started. Patients with acute pain resulting from injury, acute illness, or treatment (e.g., surgery) typically know exactly when their pain began. Those with chronic pain may be less able to identify when the pain started. Establish the *duration* of the pain (how long it has lasted). This information helps to determine whether the pain is acute or chronic and assists in identifying the cause of the pain. For example, a patient with advanced cancer who also has chronic low back pain from spinal stenosis reports a sudden, severe pain in the back that began 2 days ago. Knowing the onset and duration can lead to a diagnostic workup that may reveal new metastatic disease in the spine.

TABLE 9-6 NURSING ASSESSMENT

Pain

Subjective Data

Important Health Information

Health history: Pain history includes onset, location, intensity, quality, patterns, aggravating and alleviating factors, and expression of pain; coping strategies; past treatments and their effectiveness; review of health care utilization related to the pain problem (e.g., emergency department visits, treatment at pain clinics, visits to primary health care providers and specialists)

Medications: Use of any prescription or over-the-counter, illicit, or herbal products for pain relief; alcohol use

Functional Health Patterns

Health perception–health management: Social and work history; mental health history; smoking history; effects of pain on emotions, relationships, sleep, and activities; interviews with family members; records from psychiatric treatment related to the pain

Elimination: Constipation related to opioid drug use

Activity-exercise: Fatigue, limitations in activities, pain related to muscle use

Sexuality-reproductive: Decreased libido

Coping–stress tolerance: Psychologic evaluation using standardized measures to examine coping style, depression, anxiety

Objective Data

Physical examination, including evaluation of functional limitations

Psychosocial evaluation, including mood

Pain pattern also provides clues about the cause of the pain and directs its treatment. Many types of chronic pain (e.g., arthritis pain) increase and decrease over time. A patient may have pain all the time (constant, around-the-clock pain), as well as discrete periods of intermittent pain.

Breakthrough pain (BTP) is transient, moderate to severe pain that occurs in patients whose baseline persistent pain is otherwise mild to moderate and fairly well controlled. The average peak of BTP can be 3 to 5 minutes, and can last up to 30 minutes or even longer. BTP can either be predictable or unpredictable, and patients can have one to many episodes per day. Several transmucosal fentanyl products are specifically used to treat BTP.

End-of-dose failure is pain that occurs before the expected duration of a specific analgesic. It should not be confused with BTP. Pain that occurs at the end of the duration of an analgesic often leads to a prolonged increase in the baseline persistent pain. For example, in a patient on transdermal fentanyl (Duragesic patches) the typical duration of action is 72 hours. An increase in pain after 48 hours on the drug would be characterized as end-of-dose failure. End-of-dose failure signals the need for changes in the dose or scheduling of the analgesic. Episodic, procedural, or *incident pain* is a transient increase in pain that is caused by a specific activity or event that precipitates pain. Examples include dressing changes, movement, position changes, and procedures such as catheterization.

Location. Determining the *location* of pain assists in identifying possible causes and treatment. Some patients may be able to specify the precise location(s) of their pain, whereas others may describe general areas or comment that they "hurt all over." The location of the pain may also be referred from its origin to another site (see Fig. 9-2). For example, myocardial infarction can result in pain in the left shoulder. Pain may also radiate from its origin to another site. For example, angina pectoris can radiate from the chest to the jaw or down the left arm. This is referred to as radiating pain. *Sciatica* is pain that follows the course of the sciatic nerve. It may originate from joints or muscles around the back or from compression or damage to the sciatic nerve. The pain is projected along the course of the peripheral nerve, causing painful shooting sensations down the back of the thigh and inside of the leg to the foot.

Obtain information about the location of pain by asking the patient to (1) describe the site(s) of pain, (2) point to painful areas on the body, or (3) mark painful areas on a pain map (see eFig. 9-2, available on the website for this chapter). Because many patients have more than one site of pain, make certain that the patient describes every location.

Intensity. Assessing the severity, or *intensity,* of pain provides a reliable measure to determine the type of treatment and its effectiveness. Pain scales help the patient communicate pain intensity. Choice of a scale to use should be based on the patient's developmental needs and cognitive status. Most adults can rate the intensity of their pain using numeric scales (e.g., 0 = no pain, 10 = the worst pain) or verbal descriptor scales (e.g., none, a little, moderate, severe). These tools are sometimes easier for patients to use if they are oriented vertically or include a visual component. The Pain Thermometer Scale is an example of this type of scale[15] (Fig. 9-3). Other visual pain measures or scales include the Wong-Baker FACES Pain Rating Scale (see eFig. 9-3 on the website for this chapter) and the FACES Pain Scale–Revised (see eFig. 9-4 on the website for this chapter). These and other pain scales may be useful for patients with cognitive or language barriers to describe their pain.[16] Pain assessment measures for cognitively impaired adults and nonverbal adults are addressed later in this chapter.

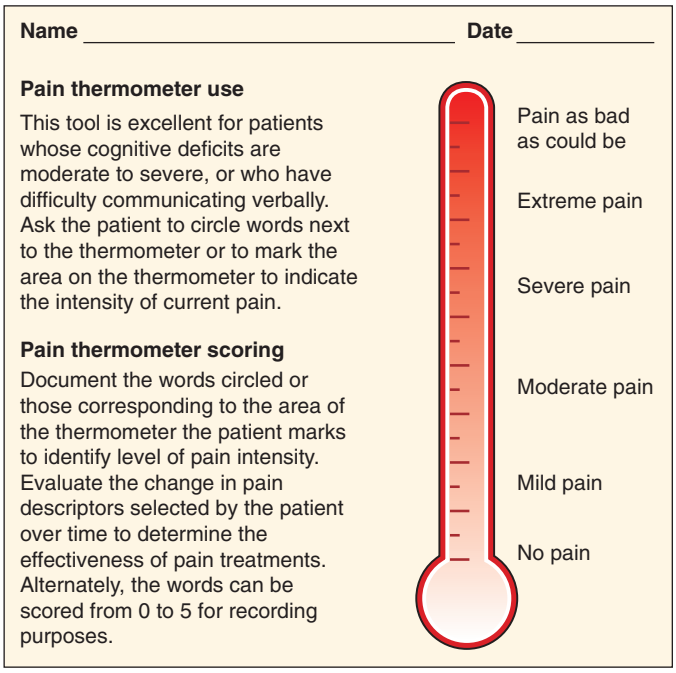

FIG. 9-3 Pain thermometer scale. Ask the patient to circle words next to the thermometer or to mark the area on the thermometer to indicate the intensity of pain. (Used with permission of Keela Herr, RN, PhD, AGSF, FAAN, The University of Iowa.)

Although intensity is an important factor in determining analgesic approaches, do not dose patients with opioids solely based on reported pain scores.[17] Opioid "dosing by numbers" without taking into account a patient's sedation level and respiratory status can lead to unsafe practices and serious adverse events. Safer analgesic administration can be achieved by balancing an amount of pain relief with analgesic side effects. Adjustments in therapy can be made to promote better pain control and minimize adverse outcomes.

Quality. The pain *quality* refers to the nature or characteristics of the pain. For example, patients often describe neuropathic pain as burning, numbing, shooting, stabbing, electric shock–like, or itchy. Nociceptive pain may be described as sharp, aching, throbbing, dull, and cramping. Since the quality of pain relates to some degree to the classification of pain (e.g., neuropathic, nociceptive, or visceral), these descriptors can help to guide treatment options that best address the specific mechanism of pain.

Associated Symptoms. *Associated symptoms* such as anxiety, fatigue, and depression may exacerbate or be exacerbated by pain. Ask about activities and situations that increase or alleviate pain. For example, musculoskeletal pain may be increased or decreased with movement and ambulation. Resting or immobilizing a painful body part can decrease pain. Knowing what makes pain better or worse can help characterize the type of pain and be helpful in selecting treatments.

Management Strategies. As people experience and live with pain, they may cope differently and be more or less willing to try different strategies to manage it. Some strategies are successful, whereas others are not. To maximize the effectiveness of the pain treatment plan, ask patients what they are using now

to control pain, what they have used in the past, and the outcomes of these methods. Strategies include prescription and nonprescription drugs and nondrug therapies such as hot and cold applications, complementary and alternative therapies (e.g., herbal products, acupuncture), and relaxation strategies (e.g., imagery). It is important to document both those that work and those that are ineffective.

Impact of Pain. Pain can have a profound influence on a patient's quality of life and functioning. In your assessment, include the effect of the pain on the patient's ability to sleep, enjoy life, interact with others, perform work and household duties, and engage in physical and social activities. Also assess the impact of pain on the patient's mood.

Patient's Beliefs, Expectations, and Goals. Patient and family beliefs, attitudes, and expectations influence responses to pain and pain treatment. Assess for attitudes and beliefs that may hinder effective treatment (e.g., the belief that opioid use will result in addiction). Ask about expectations and goals for pain management.

In an acute care setting, time limitations may dictate an abbreviated assessment. At a minimum, assess the effects of the pain on the patient's sleep and daily activities, relationships with others, physical activity, and emotional well-being. In addition, include the ways in which the patient describes the pain and the strategies used to cope with and control the pain.

Documentation

Document the pain assessment, since this is critical to ensure effective communication among team members. Many health care facilities and agencies have adopted specific tools to record an initial pain assessment, treatment, and reassessment. (An example of an initial pain assessment tool appears in eFig. 9-2 on the website for this chapter.) There also are many multidimensional pain assessment tools, such as the Brief Pain Inventory, the McGill Pain Questionnaire, the Memorial Pain Assessment Card, and the Neuropathic Pain Scale.

Reassessment

It is critical for you to reassess pain at appropriate intervals. The frequency and scope of reassessment are guided by factors such as pain severity, physical and psychosocial condition, type of intervention and risks of adverse effects, and institutional policy. For example, reassessment for a postoperative patient is done within 30 minutes of an IV dose of an analgesic. In a long-term care facility, residents with chronic pain are reassessed at least quarterly or with a change in condition or functional status.

PAIN TREATMENT

Basic Principles

All pain treatment plans are based on the following 10 principles and practice standards:

1. *Follow the principles of pain assessment* (see Table 9-5). Remember that pain is a subjective experience. The patient is not only the best judge of his or her own pain, but also the expert on the effectiveness of each pain treatment.
2. *Use a holistic approach to pain management.* The experience of pain affects all aspects of a person's life. Thus a holistic approach to assessment, treatment, and evaluation is required.[18]
3. *Every patient deserves adequate pain management.* Many patient populations, including ethnic minorities, older adults, and people with past or current substance abuse, are at risk for inadequate pain management. Be aware of your own biases and ensure that all patients are treated respectfully.
4. *Base the treatment plan on the patient's goals.* Discuss with the patient realistic goals for pain relief during the initial pain assessment. Although goals can be described in terms of pain intensity (e.g., the desire for average pain to decrease from "8/10" to "3/10"), with chronic pain conditions functional goal setting should be encouraged (e.g., a goal of performing certain daily activities, such as socializing and hobbies). Over the course of prolonged therapy, reassess these goals and progress made toward meeting them. The patient, in collaboration with the health care team, determines new goals. If the patient has unrealistic goals for therapy, such as wanting to be completely rid of all chronic arthritis pain, work with the patient to establish a more realistic goal.
5. *Use both drug and nondrug therapies.* Although drugs are often considered the mainstay of therapy, incorporate self-care activities and nondrug therapies to increase the overall effectiveness of therapy and to allow for the reduction of drug dosages to minimize adverse drug effects.[19]
6. *When appropriate, use a multimodal approach to analgesic therapy. Multimodal analgesia* is the use of two or more classes of analgesic medications to take advantage of the various mechanisms of action. This approach achieves superior pain relief, enhances patient satisfaction, and decreases adverse effects of individual drugs.[20]
7. *Address pain using an interdisciplinary approach.* The expertise and perspectives of an interdisciplinary team are often necessary to provide effective evaluation and therapies for patients with pain, especially chronic pain. Interdisciplinary teams frequently include psychology, physical and occupational therapy, pharmacy, spiritual care, and multiple medical specialties (e.g., neurology, palliative care, oncology, surgery, anesthesiology). Some pain teams also include massage therapists, music therapists, acupuncturists, and art therapists.
8. *Evaluate the effectiveness of all therapies to ensure that they are meeting the patient's goals.* Achievement of an effective treatment plan often requires trial and error. Adjustments in drug, dosage, or route are common to achieve maximal benefit while minimizing adverse effects. This trial-and-error process can become frustrating for the patient and caregivers. Reassure them that pain relief, if not pain cessation, is possible and that the health care team will continue to work with them to achieve adequate pain relief.
9. *Prevent and/or manage medication side effects.* Side effects are a major reason for treatment failure and nonadherence. Side effects are managed in one of several ways, as described in Table 9-7. You play a key role in monitoring for and treating side effects, and in teaching patients and caregivers how to minimize these effects.
10. *Incorporate patient and caregiver teaching throughout assessment and treatment.* Content should include information about the causes of the pain, pain assessment methods, treatment goals and options, expectations of pain management, proper use of drugs, side effect management, and nondrug and self-help pain relief measures. Document the teaching, and include evaluation of patient and caregiver comprehension.

TABLE 9-7 DRUG THERAPY

Managing Side Effects of Pain Medications

Side effects can be managed in one or more of the following methods.

- Decreasing the dose of analgesic by 10%-15%
- Changing to a different medication in the same class
- Adding a drug to counteract the adverse effect of the analgesic (e.g., using a stool softener for patients experiencing opioid-induced constipation)
- Using an administration route that minimizes drug concentrations (e.g., intraspinal administration of opioids used to minimize high drug levels that produce sedation, nausea, and vomiting)

Drug Therapy for Pain

Pain medications generally are divided into three categories: nonopioids, opioids, and adjuvant drugs. Treatment regimens may include medications from one or more of these groups. Mild pain often can be relieved using nonopioids alone. Moderate to severe pain usually requires an opioid. Certain types of pain, such as neuropathic pain, typically require adjuvant drug therapy alone or in combination with an opioid or another class of analgesics. Pain caused by specific medical conditions, such as cancer, may be treated with chemotherapy or radiation therapy as well as pain medications.

Nonopioids. Nonopioid analgesics include acetaminophen, aspirin and other salicylates, and NSAIDs (Table 9-8). These agents are characterized by the following: (1) their analgesic properties have an **analgesic ceiling;** that is, increasing the dose beyond an upper limit provides no greater analgesia; (2) they do not produce tolerance or physical dependence; and (3) many are available without a prescription. Monitor over-the-counter (OTC) analgesic use to avoid serious problems related to drug interactions, side effects, and overdose.

Nonopioids are effective for mild to moderate pain. They are often used in conjunction with opioids because they allow for effective pain relief using lower opioid doses (thereby causing fewer opioid side effects). This phenomenon is called the *opioid-sparing effect.*[21]

Aspirin is effective for mild pain, but its use is limited by its common side effects, including increased risk for bleeding, especially gastrointestinal (GI) bleeding. Other salicylates such as choline magnesium trisalicylate (Trilisate) cause fewer GI disturbances and bleeding abnormalities. Similar to aspirin, acetaminophen (Tylenol) has analgesic and antipyretic effects, but unlike aspirin, it has no antiplatelet or antiinflammatory effects. Although acetaminophen is well tolerated, it is metabolized by the liver. Hepatotoxicity may result from chronic dosing of more than 4 g/day, acute overdose, or use by patients with severe preexisting liver disease. The addition of acetaminophen to opioid therapy produces an opioid-sparing effect, lower pain scores, and fewer side effects, which is the reason for opioid-acetaminophen combinations such as Percocet and Lortab.[22] IV acetaminophen (OFIRMEV) is used for the treatment of acute mild to moderate pain and moderate to severe pain as an adjunct to opioid analgesics or part of a multimodal analgesic regimen, and reduction of fever. IV acetaminophen is administered over 15 minutes, and the daily dose should also not exceed 4 g/day.

NSAIDs represent a broad class of drugs with varying efficacy and side effects. All NSAIDs inhibit cyclooxygenase (COX), the enzyme that converts arachidonic acid into prostaglandins and related compounds. The enzyme has two forms: COX-1 and COX-2. COX-1 is found in almost all tissues and is responsible for several protective physiologic functions. In contrast, COX-2 is produced mainly at the sites of tissue injury, where it mediates inflammation (Fig. 9-4). Inhibition of COX-1 causes many of the untoward effects of NSAIDs, such as

TABLE 9-8 DRUG THERAPY

Selected Nonopioid Analgesics

Drug	Nursing Considerations
Nonsalicylate	
acetaminophen (Tylenol)	• Rectal suppository and injectable form (OFIRMEV) available; sustained-release preparations available; maximum daily dose of 3-4 g. • Doses >4 g/day may cause hepatotoxicity. • Acute overdose: acute liver failure. • Chronic overdose: liver toxicity.
Salicylates	
aspirin	• Rectal suppository and sustained-release preparations available. • Possibility of upper GI bleeding. • Used more commonly in low doses as a cardioprotective measure than for its analgesic properties.
choline magnesium trisalicylate (Trilisate)	• Unlike aspirin and NSAIDs, does not increase bleeding time.
Nonsteroidal Antiinflammatory Drugs (NSAIDs)	
ibuprofen (Motrin, Nuprin, Advil)	• Use lowest effective dose for shortest possible duration. • Increased risk of serious GI adverse events (bleeding, ulceration, perforation), especially in older adults. • May increase risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke. • May increase risk of hypertension and renal insufficiency.
naproxen (Naprosyn, Aleve)	• Use lowest effective dose for shortest possible duration. • Increased risk of serious GI adverse events (bleeding, ulceration, perforation), especially in older adults. • Contraindicated for the treatment of perioperative pain in setting of coronary artery bypass graft (CABG) surgery.
ketorolac (Toradol)	• Limit treatment to 5 days. • May precipitate renal failure in dehydrated patients.
diclofenac K (Cataflam)	• Use lowest effective dose for shortest possible duration. • Available in oral, ophthalmic, topical preparations.
celecoxib (Celebrex)	• Causes fewer GI side effects (e.g., bleeding) than other NSAIDs but risk still present. Is more costly than other NSAIDs. • May increase risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke. • Risks may increase with duration of use, preexisting cardiovascular disease, or risk factors for cardiovascular disease.

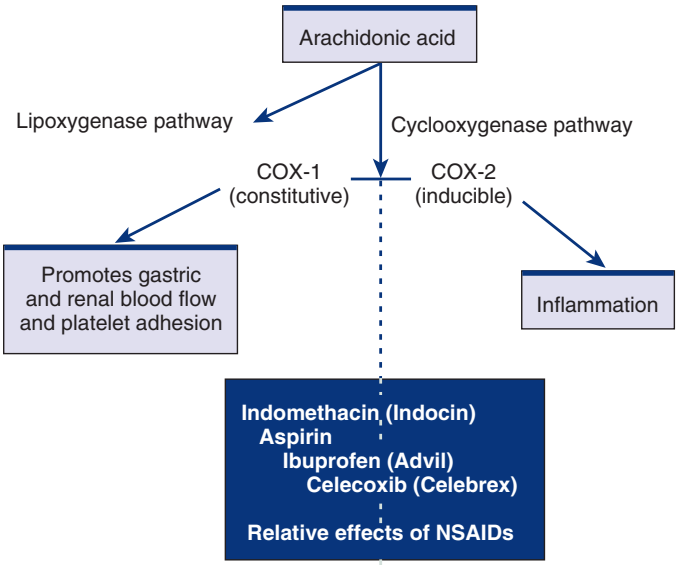

FIG. 9-4 Arachidonic acid is oxidized by two different pathways: lipoxygenase and cyclooxygenase. The cyclooxygenase pathway leads to two forms of the enzyme cyclooxygenase: COX-1 and COX-2. COX-1 is known as *constitutive* (always present), and COX-2 is known as *inducible* (its expression varies markedly depending on the stimulus). Nonsteroidal antiinflammatory drugs (NSAIDs) differ in their actions, with some having more effects on COX-1 and others more on COX-2. Indomethacin acts primarily on COX-1, whereas ibuprofen is equipotent on COX-1 and COX-2. Celecoxib primarily inhibits COX-2.

impairment of renal function, bleeding tendencies, GI irritation, and ulceration. Inhibition of COX-2 is associated with the therapeutic, antiinflammatory effects of NSAIDs. (Celecoxib [Celebrex] is a COX-2 inhibitor.) Older NSAIDs, such as ibuprofen, inhibit both forms of COX and are referred to as nonselective NSAIDs.

Patients vary greatly in their responses to a specific NSAID, so when one NSAID does not provide relief, another should be tried. NSAIDs are associated with many side effects, including GI problems ranging from dyspepsia to life-threatening ulceration and hemorrhage. NSAIDs can also cause cognitive impairment and hypersensitivity reactions with asthma-like symptoms.

Individuals at risk for NSAID-associated GI toxicity include those who have a recent history of peptic ulcer disease, patients who are older than 65, and those concurrently using corticosteroids or anticoagulants. If NSAIDs are used in patients at risk for GI bleeding, they should have concomitant therapy with a misoprostol (Cytotec) or a proton pump inhibitor (PPI) such as omeprazole (Prilosec). NSAIDs should not be administered concurrently with aspirin, since this increases the risk for GI bleeding.[23]

DRUG ALERT

Nonsteroidal Antiinflammatory Drugs (NSAIDs)

- NSAIDs (except aspirin) have been linked to a higher risk for cardiovascular events such as myocardial infarction, stroke, and heart failure.
- Patients who have just had heart surgery should not take NSAIDs.

Opioids. Opioids (Table 9-9) produce their effects by binding to receptors in the CNS. This results in (1) inhibition of the transmission of nociceptive input from the periphery to the spinal cord, (2) altered limbic system activity, and (3) activation of the descending inhibitory pathways that modulate transmission in the spinal cord. Thus opioids act on several nociceptive processes.

Types of Opioids. Opioids are categorized according to their physiologic action (i.e., agonist and antagonist) and binding at specific opioid receptors (e.g., mu, kappa, and delta). The most commonly administered subclass of opioids is the opioid pure agonists, or morphine-like opioids, which bind to mu receptors.

Opioid agonists are used for both acute and chronic pain. Although nociceptive pain appears to be more responsive to opioids than neuropathic pain, opioids are used to treat both types of pain. Pure opioid agonists include morphine, oxycodone (OxyContin), hydrocodone, codeine, methadone, hydromorphone (Dilaudid), oxymorphone (Opana, Opana ER), and levorphanol (Levo-Dromoran) (see Table 9-9). These drugs are effective for moderate to severe pain because they are potent, have no analgesic ceiling, and can be administered through several routes. When opioids are prescribed for moderate pain, they are usually combined with a nonopioid analgesic such as acetaminophen (e.g., codeine plus acetaminophen [Tylenol #3], or hydrocodone plus acetaminophen [Vicodin] or ibuprofen [Vicoprofen]). Addition of acetaminophen or NSAIDs limits the total daily dose that can be given.

Methadone is a unique mu opioid receptor agonist. When methadone is first administered, it has a relatively short analgesic action (4 to 6 hours) and can be titrated every few days, similar to other short-acting oral opioids. However, after 3 or 4 days of regular dosing, the drug's half-life can become prolonged (90 to 120 hours). Doses should not be increased more than once every 1 to 2 weeks to avoid accumulation. Overdose can result in respiratory depression, leading to death.

DRUG ALERT

Morphine

- Morphine may cause respiratory depression.
- If respirations are 12 or less breaths per minute, withhold medication and contact the health care provider.

DRUG ALERT

Methadone (Dolophine)

- Methadone may cause respiratory depression.

Mixed *agonist-antagonists* (e.g., nalbuphine [Nubain], pentazocine [Talwin], butorphanol [Stadol]) bind as agonists on kappa receptors and as weak antagonists or partial agonists on mu receptors. Because of this difference in binding, mixed agonist-antagonists produce less respiratory depression than drugs that act only at mu receptors. These drugs cause more dysphoria and agitation. In addition, opioid agonist-antagonists have an analgesic ceiling and can precipitate withdrawal if used by a patient who is physically dependent on mu agonist drugs. Partial opioid agonists (e.g., buprenorphine [Buprenex]) bind weakly to mu and kappa receptors, which decreases their analgesic efficacy. Agonist-antagonists and partial agonists currently have limited clinical application in pain management.

Mixed Mu Agonist Opioid and Dual Mechanism Agents. Some analgesics have two distinct actions, or dual mechanisms. Tramadol (Ultram) is a weak mu agonist and also inhibits the reuptake of norepinephrine and serotonin. It is effective in low back pain, osteoarthritis, fibromyalgia, diabetic peripheral neuropathic pain, polyneuropathy, and postherpetic neuralgia. The most common side effects are similar to those of other opioids, including nausea, constipation, dizziness, and sedation. As with other medications that increase serotonin and norepinephrine,

TABLE 9-9 DRUG THERAPY

Opioid Analgesics

Drug	Routes of Administration	Nursing Considerations
Mu Agonists		
morphine (Roxanol, MSIR, MS Contin, Avinza, Kadian, Epimorph, Oramorph SR)	PO (short-acting and sustained-release forms), rectal, IV, subcutaneous, epidural, intrathecal, sublingual	• Standard of comparison for opioid analgesics (Table 9-10). • Indicated for moderate to severe pain. • Can stimulate histamine release, leading to pruritus, with systemic administration. • Tablets for sustained-release preparations are to be swallowed whole, and must not be broken, chewed, dissolved, or crushed. • Preparations for neuraxial* administration must be preservative free.
hydromorphone (Dilaudid)	PO (short-acting and sustained-release forms), rectal, IV, subcutaneous, epidural, intrathecal	• Slightly shorter duration than morphine. • Indicated for moderate to severe pain. • Preparations for neuraxial* administration must be preservative free.
methadone (Dolophine)	PO, IV, IM	• High oral and rectal bioavailability. • Accumulates with repeated dosing. • Use with caution in older adults. • Risk of QT interval prolongation with high doses.
levorphanol (Levo-Dromoran)	PO, IV, IM, subcutaneous	• Accumulates with repeated dosing.
fentanyl (Sublimaze [IV], Duragesic [transdermal], Actiq [transmucosal]), buccal tablet (Fentora), sublingual (Abstral), buccal soluble film (Onsolis), nasal spray (Lazanda)	IV, epidural, intrathecal, transmucosal, transdermal	• Immediate onset after IV route; 7-8 min after IM route; 5-15 min after transmucosal route; up to 6 hr after transdermal route. • For procedures, IV fentanyl often combined with benzodiazepines for analgesia and sedation. • Very potent—dosage is in micrograms (mcg). • Transdermal fentanyl only indicated for chronic pain and should not be administered to opioid-naive patients.
oxymorphone (Opana, Opana ER)	IV, PO (short-acting and extended-release forms)	• Tablets for extended-release forms are to be swallowed whole, and must not be broken, chewed, dissolved, or crushed. • Use with caution in older and debilitated patients and patients with hepatic and renal impairment.
oxycodone (Roxicodone, OxyContin) oxycodone plus acetaminophen (Percocet, Endocet, Tylox) oxycodone plus aspirin (Percodan) oxycodone plus ibuprofen (Combunox)	PO (short-acting and sustained-release forms)	• Available as single entity and in combination with a nonopioid. • Can be used similarly to oral morphine for moderate to severe pain. • Often combined with a nonopioid for acute, moderate pain.
hydrocodone (with acetaminophen [Lortab, Vicodin, Zydone])	PO (short acting) Only available in combination with co-analgesics (acetaminophen, aspirin, or ibuprofen)	• Used for moderate or moderately severe pain. • Generally indicated for short-term management of acute pain (e.g., trauma, musculoskeletal).
codeine oral (with acetaminophen [Tylenol #3]), codeine injectable	PO, subcutaneous	• Associated with higher incidence of nausea and constipation than other mu agonists. • Many codeine preparations are combined with acetaminophen. • 5%-10% of European Americans lack the enzyme to metabolize codeine to morphine.
tramadol (Ultram)	PO, short acting and extended release	• Dual mechanism of action: mu opioid agonist and blocks reuptake of norepinephrine and serotonin. • Used for moderate pain.
tapentadol (Nucynta)	PO, short acting and extended release	• Dual mechanism of action: mu opioid agonist and blocks reuptake of norepinephrine and serotonin.
Mixed Agonist-Antagonists		
pentazocine (Talwin)	Formulated in combination with acetaminophen, aspirin, ibuprofen	• May cause psychotomimetic effects (e.g., hallucinations) and may precipitate withdrawal in opioid-dependent patients.
pentazocine plus naloxone (Talwin NX)	Abuse-deterrent preparation includes naloxone to discourage parenteral abuse	• Not recommended for treatment of chronic pain and rarely for acute pain.
butorphanol (Stadol)	Available in a nasal spray and injectable form Not available orally	• Psychotomimetic effects lower than with pentazocine. • May precipitate withdrawal in opioid-dependent patients. • Injectable used for acute pain. • Nasal spray indicated for migraine headaches.
Partial Agonists		
buprenorphine injectable (Buprenex) buprenorphine plus naloxone sublingual (Suboxone)	Sublingual and injectable forms	• Should not be chewed or swallowed. • Lower abuse potential than morphine. Does not produce psychotomimetic effects. • Buprenorphine plus naloxone used as a sublingual preparation to treat opioid dependence for easier withdrawal when necessary to taper from opioids. • May precipitate withdrawal in opioid-dependent patients. Not readily reversed by naloxone.

*Neuraxial anesthesia pertains to local anesthetics placed around the nerves of the central nervous system such as spinal and epidural anesthesia.

TABLE 9-10 OPIOID EQUIANALGESIC DOSES*

Drug	Dose Equal to Parenteral Morphine 10 mg: Oral (mg)	Dose Equal to Parenteral Morphine 10 mg: Parenteral (IM, IV, Subcutaneous) (mg)
Morphine	30	10
Codeine	200	120-130
Fentanyl	NA	0.1 (100 mcg)
Hydrocodone	30	NA
Hydromorphone	7.5	1.5
Levorphanol	4	2
Meperidine	300	75
Methadone	20	10
Oxycodone	15-30	NA
Oxymorphone	NA	1

*All equivalencies should be considered approximations. These amounts can be affected by many factors, including interpatient variability, type of pain, and tolerance. Monitor patients for effectiveness and adverse reactions and adjust the dose accordingly
NA, Not available.

this drug should be avoided in patients with a history of seizures because it lowers seizure threshold.

Tapentadol (Nucynta) is a centrally acting analgesic that works at mu receptors and inhibits norepinephrine reuptake.[24] It is approved for management of moderate to severe acute pain. For chronic moderate to severe pain, an extended-release formula is available. The side effects are similar to those of conventional opioids, except that this drug is associated with less nausea and constipation.

Opioids to Avoid. Some opioids should be avoided for pain relief because of limited efficacy and/or toxicities. Meperidine (Demerol) or pethidine is associated with neurotoxicity (e.g., seizures) caused by accumulation of its metabolite, normeperidine. Its use is limited for very short-term (i.e., less than 48 hours) treatment of acute pain when other opioid agonists are contraindicated.[25]

DRUG ALERT

Meperidine (Demerol)

The American Pain Society does not recommend the use of meperidine as an analgesic.

Side Effects of Opioids. Common side effects of opioids include constipation, nausea and vomiting, sedation, respiratory depression, and pruritus. With continued use, many side effects diminish; the exception is constipation. Less common side effects include urinary retention, myoclonus, dizziness, confusion, and hallucinations. *Constipation* is the most common side effect of opioids. Left untreated, constipation may increase the individual's pain and can lead to fecal impaction and paralytic ileus.

Because tolerance to opioid-induced constipation does not develop, a bowel regimen should be instituted at the beginning of opioid therapy and continued for as long as the person takes opioids. Although dietary roughage, fluids, and exercise should be encouraged, these measures alone may not be sufficient. Most patients should use a gentle stimulant laxative (e.g., senna) plus a stool softener (e.g., docusate sodium [Colace]). Other agents (e.g., milk of magnesia, bisacodyl [Dulcolax], polyethylene glycol [MiraLAX], or lactulose [Constulose]) can be added if necessary.

Methylnaltrexone (Relistor) is a peripheral opioid receptor antagonist used for opioid-induced constipation in patients with advanced disease (e.g., incurable cancer, heart failure, chronic obstructive pulmonary disease) when the response to traditional laxative therapy is insufficient. It is generally administered subcutaneously once a day every other day or less frequently, but not more frequently that once daily.

Nausea is often a problem in opioid-naive patients. The use of an antiemetic such as ondansetron (Zofran), metoclopramide (Reglan), transdermal scopolamine (Transderm Scōp), hydroxyzine (Vistaril), or a phenothiazine (e.g., prochlorperazine [Compazine]) can prevent or minimize nausea and vomiting until tolerance develops, usually within 1 week. Opioids delay gastric emptying (patient complains of gastric fullness), and this effect can be reduced by metoclopramide. If nausea and vomiting are severe and persistent, changing to a different opioid may be necessary.

Sedation is usually seen in opioid-naive patients being treated for acute pain. Hospitalized patients receiving opioid analgesics for acute pain should be monitored regularly, especially in the first few days after surgery. Be aware that the risk for unintended advancing sedation in postoperative patients is greatest within 4 hours after leaving the postanesthesia care unit. Opioid-induced sedation resolves with the development of tolerance. Persistent sedation with chronic opioid use can be effectively treated with psychostimulants such as caffeine, dextroamphetamine (Dexedrine), methylphenidate (Ritalin), or the anticataleptic drug modafinil (Provigil).

The risk of *respiratory depression* is also higher in opioid-naive, hospitalized patients who are treated for acute pain. Clinically significant respiratory depression is rare in opioid-tolerant patients and when opioids are titrated to analgesic effect. Patients most at risk for respiratory depression include those who are age 65 or older, have a history of snoring or witnessed apneic episodes, report excessive daytime sleepiness, have underlying cardiac or lung disease, are obese (body mass index greater than 30 kg/m^2), have a history of smoking (more than 20 pack-years), or are receiving other CNS depressants (e.g., sedatives, benzodiazepines, antihistamines). For postoperative patients the greatest risk for opioid-related respiratory adverse events is within the first 24 hours after surgery. Clinically significant respiratory depression cannot occur in patients who are fully awake. Frequently monitor both the sedation level and respiratory rate in patients receiving opioid analgesics. An extensive evidence-based, expert consensus report outlines the risks for unintended advancing sedation and respiratory depression with opioids and recommendations for monitoring to deliver quality and safe patient care.[20]

A sedation scale can be used for monitoring and providing appropriate interventions based on the level of sedation (Table 9-11).

SAFETY ALERT

- If the patient's respirations fall below 8 or 10 breaths/minute and the sedation level is 5 or greater, you should vigorously stimulate the patient and try to keep the patient awake.[20]
- If the patient becomes oversedated, administer oxygen.
- In this situation, the opioid dose should be reduced.

For patients who are excessively sedated or unresponsive, naloxone (Narcan), an opioid antagonist that rapidly reverses the effects of opioids, can be administered. Naloxone can be given IV or subcutaneously every 2 minutes. If the patient has been taking opioids regularly for more than a few days, use naloxone judiciously and titrate carefully because it can precipitate severe, agonizing pain; profound withdrawal symptoms;

TABLE 9-11 PASERO OPIOID-INDUCED SEDATION SCALE (POSS) WITH INTERVENTIONS

Level of Sedation	Nursing Intervention
S = Sleep, easy to arouse	• Acceptable • No action necessary • May increase opioid dose if needed
1 Awake and alert	• Acceptable • No action necessary • May increase opioid dose if needed
2 Slightly drowsy, easily aroused	• Acceptable • No action necessary • May increase opioid dose if needed
3 Frequently drowsy, arousable, drifts off to sleep during conversation	• Unacceptable • Monitor respiratory status and sedation level closely until sedation level is stable at less than 3 and respiratory status is satisfactory • Decrease opioid dose 25% to 50% or notify health care provider or anesthesiologist for orders • Consider administering a non-sedating, opioid-sparing nonopioid, such as acetaminophen or an NSAID, if not contraindicated
4 Somnolent, minimal or no response to verbal or physical stimulation	• Unacceptable • Stop opioid • Consider administering naloxone • Notify health care provider or anesthesiologist • Monitor respiratory status and sedation level closely until sedation level is stable at less than 3 and respiratory status is satisfactory

Adapted from Pasero C: Assessment of sedation during opioid administration for pain management, *Journal of PeriAnesthesia Nursing* 24:186, 2009.

hypertension; and pulmonary edema. Because naloxone's half-life is shorter than that of most opiates, monitor the patient's respiratory rate because it can drop again as soon as 20 minutes after naloxone administration.

Pruritus (itching) is another common side effect of opioids and occurs most frequently when opioids are administered via neuraxial (i.e., epidural, intrathecal) routes. Management of opioid-induced pruritus may include low-dose infusions of naloxone.

A rare but concerning problem with long-term and even short-term use of high-dose opioids is *opioid-induced hyperalgesia* (OIH). OIH is a state of nociceptive sensitization caused by exposure to opioids. It is characterized by a paradoxic response in which patients actually become more sensitive to certain painful stimuli and report increased pain with opioid use. The exact mechanism for this phenomenon is not clearly understood, but it may be due to neuroplasticity changes. This may explain why opioids tend to lose their effectiveness in certain patients over time.

Adjuvant Analgesic Therapy. These medications comprise classes of drugs that can be used alone or in conjunction with opioid and nonopioid analgesics. Generally, these agents were developed for other purposes (e.g., antiseizure drugs, antidepressants) and found later to be effective for pain. Commonly used analgesic adjuvants are listed in Table 9-12.

Corticosteroids. These drugs, which include dexamethasone, prednisone, and methylprednisolone (Medrol), are used for management of acute and chronic cancer pain, pain secondary to spinal cord compression, and inflammatory joint pain syndromes. Mechanisms of action are unknown but may be related to the ability of corticosteroids to decrease edema and inflammation. They also may decrease activation of an inflamed neuron. Because of this effect, corticosteroids are useful when injected epidurally for acute or subacute disc herniations.

Corticosteroids have many side effects, especially when given chronically in high doses. Adverse effects include hyperglycemia, fluid retention, dyspepsia and GI bleeding, impaired healing, muscle wasting, osteoporosis, adrenal suppression, and susceptibility to infection. Because they act through the same final pathway as NSAIDs, corticosteroids should not be given at the same time as NSAIDs.

Antidepressants. Tricyclic antidepressants (TCAs) enhance the descending inhibitory system by preventing the cellular reuptake of serotonin and norepinephrine. Higher levels of serotonin and norepinephrine in the synaptic cleft inhibit the transmission of nociceptive signals in the CNS. Other potential beneficial actions of TCAs include sodium channel modulation, α_1-adrenergic antagonist effects, and a weak NMDA receptor modulation. They appear to be effective for a variety of pain syndromes, especially neuropathic pain syndromes. However, side effects such as sedation, dry mouth, blurred vision, and weight gain limit their usefulness. Antidepressants that selectively inhibit reuptake of serotonin and norepinephrine (in particular the SNRIs) are effective for many neuropathic pain syndromes and have fewer side effects than the TCAs. These agents include venlafaxine, desvenlafaxine (Pristiq), duloxetine, milnacipran (Savella), and bupropion. A disadvantage to their use is higher cost compared with TCAs.

Antiseizure Drugs. Antiseizure drugs affect both peripheral nerves and the CNS in several ways, including sodium channel modulation, central calcium channel modulation, and changes in excitatory amino acids and other receptors. Agents such as gabapentin, lamotrigine, and pregabalin are valuable adjuvant agents in chronic pain therapy and are being increasingly used in the treatment of acute pain.

GABA Receptor Agonist. Baclofen, an analog of the inhibitory neurotransmitter GABA, can interfere with the transmission of nociceptive impulses and is mainly used for muscle spasms. It crosses the blood-brain barrier poorly and is much more effective for spasticity when delivered intrathecally.

α_2-Adrenergic Agonists. Clonidine and tizanidine (Zanaflex) are the most widely used α_2-adrenergic agonists. They are thought to work on the central inhibitory α-adrenergic receptors. These agents may also decrease norepinephrine release peripherally. They are used for chronic headache and neuropathic pain.

Local Anesthetics. For acute pain from surgery or trauma, local anesthetics such as bupivacaine and ropivacaine can be administered epidurally by continuous infusion, but also by intermittent or continuous infusion with regional nerve blocks. Topical applications of local anesthetics are used to interrupt transmission of pain signals to the brain. For example, 5% lidocaine patch (Lidoderm) is recommended as a first-line agent for the treatment of several types of neuropathic pain. In the treatment of chronic severe neuropathic pain that is refractory to other analgesics, oral therapy with mexiletine (Mexitil) may be tried. Systemic lidocaine administered in the form of an IV infusion is also sometimes used for neuropathic and postoperative visceral pain.

TABLE 9-12 DRUG THERAPY

Adjuvant Drugs Used for Pain

Drug	Specific Indication	Nursing Considerations
Corticosteroids	Inflammation	• Avoid high doses for long-term use.
Antidepressants		
Tricyclic Antidepressants		
amitriptyline (Elavil) doxepin (Sinequan) imipramine (Tofranil) nortriptyline (Pamelor) desipramine (Norpramin)	Neuropathic pain	• Side-effect profile differs for each agent and is often dose dependent. • Common side effects include anticholinergic effects (e.g., dry mouth) and sedation. • Monitor for anticholinergic side effects. • Titrate slowly over days to weeks to reach optimal therapeutic doses.
Serotonin Norepinephrine Reuptake Inhibitor (SNRI) Antidepressants		
venlafaxine (Effexor) duloxetine (Cymbalta) bupropion (Wellbutrin) milnacipran (Savella)	Neuropathic pain Multimodal therapy for acute pain (venlafaxine) Fibromyalgia (duloxetine)	• Side effects vary with each agent.
Antiseizure Drugs		
First generation: carbamazepine (Tegretol) phenytoin (Dilantin) *Second generation*: gabapentin (Neurontin) pregabalin (Lyrica) lamotrigine (Lamictal)	Neuropathic pain Multimodal therapy for acute pain (gabapentin, pregabalin) Fibromyalgia (pregabalin)	• Start with low doses, increase slowly. • Side effects vary with each agent.
GABA Receptor Agonist		
baclofen (Lioresal)	Neuropathic pain Muscle spasms	• Monitor for weakness, urinary dysfunction. • Avoid abrupt discontinuation because of CNS irritability.
α_2-Adrenergic Agonist		
clonidine (Duraclon) tizanidine (Zanaflex)	Particularly useful for neuropathic pain when administered intrathecally	• Side effects include sedation, orthostatic hypotension, dry mouth. • Often combined with anesthetics (e.g., bupivacaine [Sensorcaine]).
Anesthetics: Oral or Systemic		
mexiletine (Mexitil)	Diabetic neuropathy Neuropathic pain	• Monitor for side effects: high incidence of nausea, dizziness, perioral numbness, paresthesias, tremor, seizures (at high doses), dysrhythmias, and myocardial depression. • Avoid in patients with preexisting cardiac disease.
5% lidocaine–impregnated transdermal patch (Lidoderm patch)	Postherpetic neuralgia	• Local skin reactions (e.g., change in color, colored spots, irritation, itching, rash, burning) occur at the site of application; typically mild.
Anesthetics: Local		
lidocaine (L-M-X)	Topical local anesthetic cream applied to intact skin before venipuncture or lumbar puncture. Possible effective for postherpetic neuralgia	• Apply bubble layer to intact skin, wait at least 20-30 minutes before wiping and performing painful procedure. • Duration is approximately 60 minutes after removed from skin. • Available without prescription.
lidocaine 2.5% + prilocaine 2.5% (topical EMLA [eutectic mixture of local anesthetics])	Longer time to take effect than L-M-X	• Apply under an occlusive dressing (e.g., Tegaderm, DuoDerm) or on an anesthetic disk. • Side effects include mild erythema, edema, skin blanching.
capsaicin (Zostrix)	Pain associated with arthritis, postherpetic neuralgia, diabetic neuropathy	• Apply very sparingly onto affected area. Use gloves or wash hands with soap and water after application. • Monitor for side effects: skin irritation (burning, stinging) at application site and cough when inhaled.

CNS, Central nervous system.

Cannabinoids. Cannabinoid-derived medications show promise in the treatment of certain pain syndromes and symptoms. However, these preparations have sparked considerable controversy and confusion, mostly because cannabinoids are related to the cannabis plant, also known as marijuana. Synthetic cannabinoids (e.g., dronabinol [Marinol]) have been approved for medical use in Canada, the United Kingdom, and the United States. Smoking marijuana or cannabis rapidly increases plasma levels of tetrahydrocannabinol (THC), but the amount is highly dependent on composition of the marijuana cigarette and inhalation technique, so this form of use is associated with highly variable results in relief of pain and symptoms.[26] With commercially available oral preparations, the absorption and bioavailability are more reliable and predictable.

Cannabinoids exert their analgesic effects primarily through the cannabinoid-l (CB1) and CB2 receptors. Activation of cannabinoid receptors modulates neurotransmission in the serotoninergic, dopaminergic, and glutamatergic systems, as well as other systems. Cannabinoids also enhance the endogenous opioid system. Other beneficial effects include alleviation of nausea and increased appetite. They may also have opioid-sparing effects, possibly reduce opioid tolerance, and even ameliorate symptoms of opioid withdrawal.[26] In Canada an oromucosal spray, nabiximols (Sativex), is available for adjunctive treatment of neuropathic pain and moderate to severe pain in cancer.[27]

Administration

Scheduling. Appropriate analgesic scheduling focuses on preventing or controlling pain, rather than providing analgesics only after the patient's pain has become severe. A patient should be premedicated before procedures and activities that are expected to produce pain. Similarly, a patient with constant pain should receive analgesics around the clock rather than on an "as needed" (PRN) basis. These strategies control pain before it starts and usually result in lower analgesic requirements. Fast-acting drugs should be used for incident or breakthrough pain, whereas long-acting analgesics are more effective for constant pain. Examples of fast-acting and sustained-release analgesics are described later in this section.

Titration. *Analgesic titration* is dose adjustment based on assessment of the adequacy of analgesic effect versus the side effects produced. The amount of analgesic needed to manage pain varies widely, and titration is an important strategy in addressing this variability. An analgesic can be titrated upward or downward, depending on the situation. For example, in a postoperative patient the dose of analgesic generally decreases over time as the acute pain resolves. On the other hand, opioids for chronic, severe cancer pain may be titrated upward many times over the course of therapy to maintain adequate pain control. The goal of titration is to use the smallest dose of analgesic that provides effective pain control with the fewest side effects.

Equianalgesic Dosing. The term **equianalgesic dose** refers to a dose of one analgesic that is approximately equivalent in pain-relieving effects to a given dose of another analgesic (see Table 9-10). This equivalence helps guide opioid dosing when changing routes or opioids when a particular drug is ineffective or causes intolerable side effects. Equianalgesic charts and conversion programs are widely available in clinical guidelines, in health care facility pain protocols, and on the Internet. They are useful tools, but you need to understand their limitations, since equianalgesic doses are estimates.[28] All changes in opioid therapy must be carefully monitored and adjusted for an individual patient.

Administration Routes. Opioids and other analgesic agents can be delivered via many routes. This flexibility allows the health care provider to (1) target a particular anatomic source of the pain, (2) achieve therapeutic blood levels rapidly when necessary, (3) avoid certain side effects through localized administration, and (4) provide analgesia when patients are unable to swallow. The following discussion highlights the uses and nursing considerations for analgesic agents delivered through a variety of routes.

Oral. Generally, oral administration is the route of choice for the person with a functioning GI system. Most pain medications are available in oral preparations, such as liquid and tablet. For opioids, larger oral doses are needed to achieve the equivalent analgesia of doses administered intramuscularly (IM) or IV (see Table 9-10). For example, 10 mg of parenteral morphine is equivalent to approximately 30 mg of oral morphine. The reason larger doses are required is related to the *first-pass effect* of hepatic metabolism. This means that oral opioids are absorbed from the GI tract into the portal circulation and shunted to the liver. Partial metabolism in the liver occurs before the drug enters the systemic circulation and becomes available to peripheral receptors or can cross the blood-brain barrier and access CNS opioid receptors, which is necessary to produce analgesia. Oral opioids are as effective as parenteral opioids if the dose administered is large enough to compensate for the first-pass metabolism.

Many opioids are available in short-acting (immediate-release) and long-acting (sustained-release or extended-release) oral preparations. Immediate-release products are effective in providing rapid, short-term pain relief. Sustained-release preparations generally are administered every 8 to 12 hours, although some preparations (e.g., Kadian, Avinza, Exalgo) may be dosed every 24 hours. Sustained- or extended-release preparations should not be crushed, broken, or chewed.

Transmucosal and Buccal Routes. Although morphine has historically been administered sublingually to people with cancer pain who have difficulty swallowing, little of the drug is actually absorbed from the sublingual tissue. Instead, most of the drug is dissolved in saliva and swallowed, making its metabolism the same as that of oral morphine.

Several transmucosal fentanyl products are used for the treatment of breakthrough pain including oral transmucosal fentanyl citrate (OTFC) (Actiq) with the fentanyl embedded in a flavored lozenge on a stick, absorbed by the buccal mucosa after being rubbed actively over it when administered as the lozenge (not sucked as a lollipop), fentanyl buccal tablet (FBT) (Fentora) in the form of a buccal tablet that disintegrates, fentanyl sublingual (Abstral), and fentanyl buccal soluble film (Onsolis) for application to the buccal membrane. Transmucosal absorption allows the drug to enter the bloodstream and travel directly to the CNS. Pain relief typically occurs 5 to 7 minutes after administration. These formulations of fentanyl should be used only for patients who are already receiving and are tolerant to opioid therapy.

An oromucosal spray delivery of cannabinoid extract (Sativex) is an adjunctive treatment for neuropathic pain and spasticity in patients with multiple sclerosis. It is not currently available in the United States.

Intranasal Route. Intranasal administration allows delivery of medication to highly vascular mucosa and avoids the first-pass effect. Butorphanol is indicated for acute headache and other intense, recurrent types of pain. A transmucosal fentanyl nasal spray (Lazanda) is available for the treatment of breakthrough pain.

Rectal. The rectal route is often overlooked but is particularly useful when the patient cannot take an analgesic by mouth, such as those patients with severe nausea and vomiting. Analgesics that are available as rectal suppositories include hydromorphone, oxymorphone, morphine, and acetaminophen. If rectal preparations are not available, many oral formulations can be given rectally if the patient is unable to take medications by mouth.

Transdermal Route. Fentanyl (Duragesic) is available as a transdermal patch system for application to nonhairy skin. This

delivery system is useful for the patient who cannot tolerate oral analgesic drugs. Absorption from the patch is slow, and it takes 12 to 17 hours to reach full effect with the first application. Therefore transdermal fentanyl is not suitable for rapid dose titration but can be effective if the patient's pain is stable and the dose required to control it is known. Patches may need to be changed every 48 hours rather than the recommended 72 hours based on individual patient responses. Rashes caused by the adhesive of the patch may be reduced by preparing the skin 1 hour before placement with a weak corticosteroid cream. Bioocclusive dressings are available if the patch keeps falling off because of sweating. A transdermal patient-controlled analgesia (PCA) system (iontophoretic transdermal system [ITS]) is available.

DRUG ALERT

Fentanyl Patches

- Fentanyl patches (Duragesic) may cause death from overdose.
- Signs of overdose include trouble breathing or shallow respirations; tiredness, extreme sleepiness, or sedation; inability to think, talk, or walk normally; and faintness, dizziness, or confusion.

An important distinction should be made between transdermal patches designed for systemic drug delivery (e.g., Duragesic) and those for topical or local delivery (e.g., Lidoderm).

A 5% lidocaine-impregnated transdermal patch (Lidoderm patch) is used for postherpetic neuralgia. The patch is placed directly on the intact skin in the area of postherpetic pain and left in place for up to 12 hours. Topical local anesthetics are generally well tolerated and cause few systemic side effects, even with chronic use.

Creams and lotions containing 10% trolamine salicylate (Aspercreme, Myoflex Creme) are available for joint and muscle pain. This aspirin-like substance is absorbed locally. This route of administration avoids GI irritation but not the other side effects of high-dose salicylates. Topical diclofenac solution and a diclofenac patch (Flector) have been shown to be effective for osteoarthritic pain of the knee.

Other topical analgesic agents, such as capsaicin (e.g., Zostrix) and lidocaine (L-M-X cream), also provide analgesia. Derived from red chili pepper, capsaicin acts on C fiber heat receptors. If used three or four times a day for 4 to 6 weeks, it will cause the C nociceptor fibers to become inactive. The result is neuronal resistance to painful stimuli. Capsaicin can control pain associated with diabetic neuropathy, arthritis, and possibly postherpetic neuralgia. L-M-X cream is useful for control of pain associated with venipunctures. Cover the targeted area of intact skin with a layer of L-M-X for at least 20 to 30 minutes before it is wiped off prior to beginning a painful procedure. An occlusive dressing is recommended but not required during this time.

Parenteral Routes. The parenteral routes include subcutaneous, IM, and IV administration. Single, repeated, or continuous dosing (subcutaneous or IV) is possible via parenteral routes. Although it is frequently used, the IM route is not recommended because injections cause significant pain and result in unreliable absorption. With chronic use, IM injections can result in abscesses and fibrosis. Onset of analgesia after subcutaneous administration is slow, and thus the subcutaneous route is rarely used for acute pain management. However, continuous subcutaneous infusions are effective for pain management at the end of life. This route is especially helpful for people with abnormal GI function and limited venous access. IV administration is the best route when immediate analgesia and rapid titration

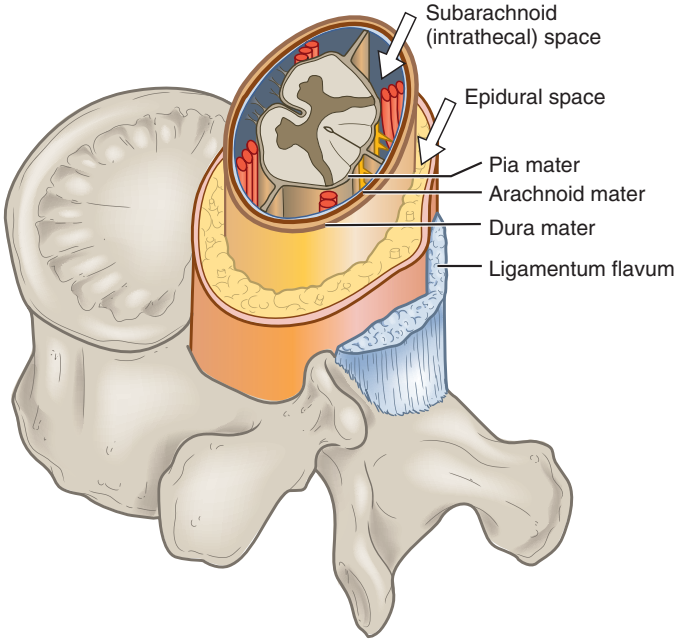

FIG. 9-5 Spinal anatomy. The spinal cord extends from the foramen magnum to the first or second lumbar vertebral space. The subarachnoid space (intrathecal space) is filled with cerebrospinal fluid that continuously circulates and bathes the spinal cord. The epidural space is a potential space filled with blood vessels, fat, and a network of nerve extensions.

are necessary. Continuous IV infusions provide excellent steady-state analgesia through stable blood levels.

Intraspinal Delivery. Intraspinal opioid therapy involves inserting a catheter into the subarachnoid space *(intrathecal delivery)* or the epidural space *(epidural delivery)* (Fig. 9-5). Analgesics are injected either by intermittent bolus doses or continuous infusion.

Percutaneously placed temporary catheters are used for short-term therapy (2 to 4 days), and surgically implanted catheters are used for long-term therapy. Although the lumbar region is the most common site of placement, epidural catheters may be placed at any point along the spinal column (cervical, thoracic, lumbar, or caudal). The tip of the epidural catheter is placed as close to the nerve supplying the painful dermatome as possible. For example, a thoracic catheter is placed for upper abdominal surgery, and a high lumbar catheter is used for lower abdominal surgery. Fluoroscopy is used to ensure correct placement of the catheter.

Intraspinally administered analgesics are highly potent because they are delivered close to the receptors in the spinal cord dorsal horn. Smaller doses of analgesics are needed than with other routes, including IV. For example, 1 mg of intrathecal morphine is approximately equivalent to 10 mg of epidural morphine, 100 mg of IV morphine, and 300 mg of oral morphine. Drugs that are delivered intraspinally include morphine, fentanyl, sufentanil (Sufenta), alfentanil (Alfenta), hydromorphone, ziconotide (Prialt) (a calcium channel receptor modulator for use in neuropathic pain syndromes), and clonidine. Nausea, itching, and urinary retention are common side effects of intraspinal opioids.

Complications of intraspinal analgesia include catheter displacement and migration, accidental infusions of neurotoxic agents, epidural hematomas, and infection. Clinical manifestations of catheter displacement or migration depend on catheter

location and the drug being infused. A catheter that migrates out of the intrathecal or epidural space will cause a decrease in pain relief with no improvement with additional boluses or increases in the infusion rate. If an epidural catheter migrates into the subarachnoid space, increased side effects become quickly apparent. Somnolence, confusion, and increased anesthesia (if the infusate contains an anesthetic) occur. Check with institutional policy before aspirating cerebrospinal fluid to determine intrathecal catheter placement. Migration of a catheter into a blood vessel may cause an increase in side effects because of systemic drug distribution.

Many drugs and chemicals are highly neurotoxic when administered intraspinally. These include many preservatives such as alcohol and phenol, antibiotics, chemotherapy agents, potassium, and parenteral nutrition. To avoid inadvertent injection of IV drugs into an intraspinal catheter, the catheter should be clearly marked as an intraspinal access device, and only preservative-free drugs should be injected.

Infection is a rare but serious complication of intraspinal analgesia. Assess the skin around the exit site for inflammation, drainage, or pain. Manifestations of an intraspinal infection include diffuse back pain, pain or paresthesia during bolus injection, and unexplained sensory or motor deficits in the lower limbs. Fever may or may not be present. Acute bacterial infection (meningitis) is manifested by photophobia, neck stiffness, fever, headache, and altered mental status. Infection is avoided by providing regular, meticulous wound care and using sterile technique when caring for the catheter and injecting drugs.

Long-term epidural catheters may be placed for terminal cancer patients or patients with certain pain syndromes that are unresponsive to other treatments. If a long-term indwelling epidural catheter is used, bacterial filters are recommended.

Implantable Pumps. Intraspinal catheters can be surgically implanted for long-term pain relief. The surgical placement of an intrathecal catheter to a subcutaneously placed pump and reservoir allows for the delivery of drugs directly into the intrathecal space. The pump, which is normally placed in a pocket made in the subcutaneous tissue of the abdomen, may be programmable or fixed. Changes are made by either reprogramming the pump or changing the mixture or concentration of drug in the reservoir. The pump is refilled every 30 to 90 days depending on flow rate, mixture, and reservoir size.

Patient-Controlled Analgesia. A specific type of IV delivery system is **patient-controlled analgesia (PCA),** or demand analgesia. It can also be connected to an epidural catheter (patient-controlled epidural analgesia). With PCA, a dose of opioid is delivered when the patient decides a dose is needed. PCA uses an infusion system in which the patient pushes a button to receive a bolus infusion of an analgesic. PCA is used widely for the management of acute pain, including postoperative pain and cancer pain.

Opioids such as morphine and hydromorphone are commonly administered via IV PCA therapy for both acute and chronic pain management. Fentanyl is less often used for acute pain. Sometimes IV PCA is administered with a continuous or background infusion called a *basal rate,* depending on the patient's opioid requirement. For acute pain (e.g., postoperative pain), basal rates are not recommended when initiating therapy in opioid-naive patients. The addition of a basal rate in opioid-naive patients and those at risk for adverse respiratory outcomes (e.g., older age, obstructive sleep apnea, pulmonary disease) may lead to serious respiratory events.[20]

Use of PCA begins with patient teaching. Help the patient understand the mechanics of getting a drug dose and how to titrate the drug to achieve good pain relief. Teach the patient to self-administer the analgesic before pain is severe. Assure the patient that he or she cannot "overdose" because the pump is programmed to deliver a maximum number of doses per hour. Pressing the button after the maximum dose is administered will not result in additional analgesic. If the maximum doses are inadequate to relieve pain, the pump can be reprogrammed to increase the amount or frequency of dosing. In addition, you can give bolus doses if they are included in the physician's orders. To make a smooth transition from infusion PCA to oral drugs, the patient should receive increasing doses of oral drug as the PCA analgesic is tapered.

Interventional Therapy

Therapeutic Nerve Blocks. Nerve blocks generally involve one-time or continuous infusion of local anesthetics into a particular area to produce pain relief. These techniques are also called *regional anesthesia.* Nerve blocks interrupt all afferent and efferent transmission to the area and thus are not specific to nociceptive pathways. They include local infiltration of anesthetics into a surgical area (e.g., chest incisions, inguinal hernia, joint) and injection of anesthetic into a specific nerve (e.g., occipital or pudendal nerve) or nerve plexus (e.g., brachial or celiac plexus). Nerve blocks often are used during and after surgery to manage pain. For longer-term relief of chronic pain syndromes, local anesthetics can be administered via a continuous infusion.

Adverse effects of nerve blocks are similar to those for local anesthetics delivered via other systemic routes and include systemic toxicity resulting in dysrhythmias, confusion, nausea and vomiting, blurred vision, tinnitus, and metallic taste. Temporary nerve blocks affect both motor function and sensation and typically last 2 to 24 hours, depending on the agent and the site of injection. Motor ability generally returns before sensation.

Neuroablative Techniques. *Neuroablative interventions* are performed for severe pain that is unresponsive to all other therapies. Neuroablative techniques destroy nerves, thereby interrupting pain transmission. Destruction is accomplished by surgical resection or thermocoagulation, including radiofrequency coagulation. Neuroablative interventions that destroy the sensory division of a peripheral or spinal nerve are classified as *neurectomies, rhizotomies,* and *sympathectomies.* Neurosurgical procedures that ablate the lateral spinothalamic tract are classified as *cordotomies* if the tract is interrupted in the spinal cord, or *tractotomies* if the interruption is in the medulla or the midbrain of the brainstem (Fig. 9-6). Both cordotomy and tractotomy can be performed with the aid of local anesthesia by a percutaneous technique under fluoroscopy.

Neuroaugmentation. *Neuroaugmentation* involves electrical stimulation of the brain and the spinal cord. Spinal cord stimulation (SCS) is performed much more often than brain stimulation. The most common use of SCS is for chronic back pain secondary to nerve damage that is unresponsive to other therapies. Other uses include complex regional pain syndrome (CRPS), spinal cord injury pain, and interstitial cystitis. Potential complications include those related to the surgery (bleeding and infection), migration of the generator (which usually is implanted in the subcutaneous tissues of the upper gluteal or pectoralis area), and nerve damage.[29]

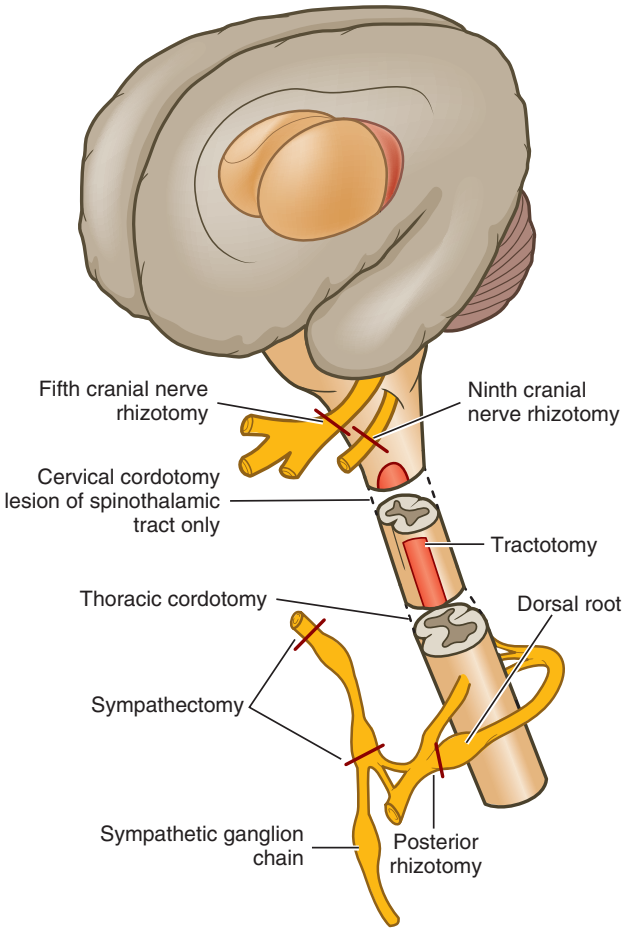

FIG. 9-6 Sites of neurosurgical procedures for pain relief.

Nondrug Therapies for Pain

Nondrug strategies play an important role in pain management (Table 9-13). They can reduce the dose of an analgesic required to relieve pain and thereby minimize side effects of drug therapy. Moreover, they increase the patient's sense of personal control about managing pain and bolster coping skills. Some strategies are believed to alter ascending nociceptive input or stimulate descending pain modulation mechanisms (see discussion on perception on p. 118). These nondrug therapies are especially important in the treatment of chronic pain.[30]

Physical Pain Relief Strategies

Massage. Massage is useful for both acute and chronic pain.[31] Many different massage techniques exist, including moving the hands or fingers over the skin slowly or briskly with long strokes or in circles (superficial massage) or applying firm pressure to the skin to maintain contact while massaging the underlying tissues (deep massage). Another type is trigger point massage. A **trigger point** is a circumscribed hypersensitive area within a tight band of muscle. It is caused by acute or chronic muscle strain and can often be felt as a tight knot under the skin. Trigger point massage is performed by applying either strong, sustained digital pressure; deep massage; or gentler massage with ice followed by muscle heating. (Massage is discussed in Chapter 6.)

Exercise. Exercise is an essential part of the treatment plan for patients with chronic pain, particularly those with musculoskeletal pain.[32] Many patients become physically deconditioned as a result of their pain, which in turn leads to more pain. Exercise acts via many mechanisms to relieve pain. It enhances circulation and cardiovascular fitness, reduces edema, increases muscle strength and flexibility, and enhances physical and psychosocial functioning. An exercise program should be tailored to the patient's physical needs and lifestyle. It may include aerobic exercise, stretching, and strengthening exercises. The program should be supervised by trained personnel (e.g., exercise physiologist, physical therapist).

TABLE 9-13 NONDRUG THERAPIES FOR PAIN

Physical Therapies	Cognitive Therapies
• Acupuncture • Application of heat and cold (see Table 9-14) • Exercise • Massage • Transcutaneous electrical nerve stimulation (TENS)	• Distraction • Hypnosis • Imagery • Relaxation strategies (see Chapter 7) • Relaxation breathing • Imagery • Meditation • Art therapy • Music therapy

Transcutaneous Electrical Nerve Stimulation. *Transcutaneous electrical nerve stimulation* (TENS) involves the delivery of an electric current through electrodes applied to the skin surface over the painful region, at trigger points, or over a peripheral nerve. A TENS system consists of two or more electrodes connected by lead wires to a small, battery-operated stimulator (Fig. 9-7). Usually a physical therapist is responsible for administering TENS therapy, although nurses can be trained in the technique.

TENS may be used for acute pain, including postoperative pain and pain associated with physical trauma. The effects of TENS on chronic pain are less clear, but it may be effective in these cases.[33]

Acupuncture. Acupuncture is a technique of Traditional Chinese Medicine in which very thin needles are inserted into the body at designated points. Acupuncture is used for many different kinds of pain. (Acupuncture is discussed in Chapter 6.)

Heat Therapy. Heat therapy is the application of either moist or dry heat to the skin. Heat therapy can be either superficial or deep. Superficial heat can be applied using an electric heating

FIG. 9-7 Transcutaneous electrical nerve stimulation (TENS) treatment being given for treatment of pain after shoulder surgery.

TABLE 9-14 PATIENT & CAREGIVER TEACHING GUIDE

Heat and Cold Therapy

Include the following instructions when teaching the patient and caregiver about superficial heat or cold techniques.

Heat Therapy

- Do not use heat on an area that is being treated with radiation therapy, is bleeding, has decreased sensation, or has been injured in the past 24 hours.
- Do not use any menthol-containing products (e.g., Ben-Gay, Vicks, Icy Hot) with heat applications because this may cause burns.
- Cover the heat source with a towel or cloth before applying to the skin to prevent burns.

Cold Therapy

- Cover the cold source with a cloth or towel before applying to the skin to prevent tissue damage.
- Do not apply cold to areas that are being treated with radiation therapy, have open wounds, or have poor circulation.
- If it is not possible to apply the cold directly to the painful site, try applying it right above or below the painful site or on the opposite side of the body on the corresponding site (e.g., left elbow if the right elbow hurts).

pad (dry or moist), a hot pack, hot moist compresses, warm wax (paraffin), or a hot water bottle. To expose large areas of the body, patients can immerse themselves in a hot bath, shower, or whirlpool. Physical therapy departments provide deep-heat therapy through such techniques as short-wave diathermy, microwave diathermy, and ultrasound therapy. Patient teaching regarding heat therapy is described in Table 9-14.

Cold Therapy. Cold therapy involves the application of either moist or dry cold to the skin. Dry cold can be applied by means of an ice bag, moist cold by means of towels soaked in ice water, cold hydrocollator packs, or immersion in a bath or under running cold water. Icing with ice cubes or blocks of ice made to resemble Popsicles is another technique used for pain relief. Cold therapy is believed to be more effective than heat for a variety of painful conditions, including acute pain from trauma or surgery, acute flare-ups of arthritis, muscle spasms, and headache. Patient teaching regarding cold therapy is described in Table 9-14.

Cognitive Therapies. Techniques to alter the affective, cognitive, and behavioral components of pain include a variety of cognitive strategies and behavioral approaches. For example, patients can identify and challenge negative pain-related thoughts and replace them with more positive coping thoughts. Some of these techniques require little training and often are adopted independently by the patient. For others, a trained therapist is necessary.

Distraction. Distraction involves redirection of attention away from the pain and onto something else. It is a simple but powerful strategy to relieve pain. Distraction can be achieved by engaging the patient in any activity that can hold his or her attention (e.g., watching TV or a movie, conversing, listening to music, playing a game). It is important to match the activity with the patient's energy level and ability to concentrate.

Hypnosis. Hypnotherapy is a structured technique that enables a patient to achieve a state of heightened awareness and focused concentration that can be used to alter the patient's pain perception. Hypnosis should be administered and monitored only by specially trained clinicians.[34]

Relaxation Strategies. Relaxation strategies are varied, but their goal is to reach a state that is free from anxiety and muscle tension. Relaxation reduces stress, decreases acute anxiety, distracts from pain, alleviates muscle tension, combats fatigue, facilitates sleep, and enhances the effectiveness of other pain relief measures.[35] Relaxation strategies include relaxation breathing, music, imagery, meditation, and muscle relaxation. These strategies are described in Chapter 7.

NURSING AND COLLABORATIVE MANAGEMENT PAIN

You are an important member of the interdisciplinary pain management team. You provide input into the assessment and reassessment of pain. You help in planning and implementing treatments, including education, advocacy, and support of the patient and family. Because patients in any care setting can experience pain, you must be knowledgeable about current therapies and flexible in trying new approaches to pain management.

Together with the patient, develop a written agreement or treatment plan that describes the pain management. The plan should ensure that pain will be treated based on the patient's perception and report of pain. In addition, the plan should clearly outline the gradual tapering of the analgesic dose, with eventual substitution of parenteral analgesics with long-acting oral preparations, and possibly cessation of opioids.

Many nursing roles are described earlier in this chapter, including assessing pain, administering treatment, monitoring for side effects, and teaching patients and caregivers. However, the success of these actions depends on your ability to establish a trusting relationship with the patient and caregiver and to address their concerns regarding pain and its treatment.

EFFECTIVE COMMUNICATION

Because pain is a subjective experience, patients need to feel confident that their reporting of pain will be believed and will not be perceived as "complaining." The patient and the caregiver also need to know that you consider the pain significant and understand that pain may profoundly disrupt a person's life. Communicate concern and commit to helping the patient obtain pain relief and cope with any unrelieved pain. Support the patient and the caregiver through the period of trial and error that may be necessary to implement an effective therapeutic plan. It also is important to clarify responsibilities in pain relief. Help the patient understand the role of the health care team members, as well as the patient's roles and expectations.

In addition to addressing specific aspects of pain assessment and treatment, evaluate the impact that the pain has on the lives of the patient and the caregiver. Table 9-15 addresses teaching needs of patients and caregivers related to pain management.

CHALLENGES TO EFFECTIVE PAIN MANAGEMENT

Common challenges to effective pain management include misunderstandings about tolerance, physical dependence, and addiction. It is important for you to understand and be able to explain these concepts.

TOLERANCE. *Tolerance* occurs with chronic exposure to a variety of drugs. In the case of opioids, tolerance to analgesia is characterized by the need for an increased opioid dose to maintain the same degree of analgesia. Although the development of

TABLE 9-15 PATIENT & CAREGIVER TEACHING GUIDE

Pain Management

Include the following information in the teaching plan for the patient with pain and caregiver.

- Self-management techniques.
- Realistic goals for pain control.
- Negative consequences of unrelieved pain.
- Need to maintain a record of pain level and effectiveness of treatment.
- Pain should be treated with drugs and/or nondrug therapies before it becomes severe.
- Medication may stop working after it is taken for a period of time, and dosages may need to be adjusted.
- Potential side effects and complications associated with pain therapies can include nausea and vomiting, constipation, sedation and drowsiness, itching, urinary retention, and sweating.
- Need to report when pain is not relieved to tolerable levels.

tolerance to side effects (except constipation) is more predictable, the incidence of clinically significant analgesic opioid tolerance in chronic pain patients is unknown, since dosage needs may increase as the disease (e.g., cancer) progresses. It is essential to assess for increased analgesic needs in patients on long-term therapy. The health care team needs to evaluate and rule out other causes of increased analgesic needs, such as disease progression or infection.

If significant tolerance to opioids develops and it is believed that an opioid is losing its effectiveness, or intolerable side effects are associated with escalation of doses, the practice of *opioid rotation* may be considered. This involves switching from one opioid to another, assuming that the new opioid will be more effective at lower equianalgesic doses. However, very high opioid doses can result in opioid-induced hyperalgesia rather than pain relief. This means that increases in the dose can lead to higher pain levels.

PHYSICAL DEPENDENCE. Like tolerance, physical dependence is a normal physiologic response to ongoing exposure to drugs. It is manifested by a withdrawal syndrome when the drug is abruptly decreased. Manifestations of opioid withdrawal are listed in Table 9-16. When opioids are no longer needed to provide pain relief, a tapering schedule should be used in conjunction with careful monitoring. A typical tapering schedule is determined by calculating the 24-hour dose used by the patient and dividing by 2. Of this decreased amount, 25% is given every 6 hours. After 2 days the daily dose is reduced by an additional 25%; this reduction continues every 2 days until the 24-hour oral dose is 30 mg (morphine equivalent) per day. After 2 days on this minimum dose, the opioid is then discontinued.

PSEUDOADDICTION. Inadequate treatment of pain can lead to a phenomenon called *pseudoaddiction*.[36] This occurs when patients exhibit behaviors commonly associated with addiction (e.g., frequent requests for analgesic refills or higher dosages), but the behaviors resolve with adequate treatment of the patient's pain. These patients are often labeled as drug-seeking, which can result in a crisis of mistrust between the patient and the provider. This phenomenon can be avoided by effective communication strategies and optimal pain management.

ADDICTION. *Addiction* is a complex neurobiologic condition characterized by aberrant behaviors arising from a drive to obtain and take substances for reasons other than the prescribed therapeutic value (see Chapter 11). Tolerance and physical dependence are not indicators of addiction. Rather they are normal physiologic responses to chronic exposure to certain drugs, including opioids. Addiction rarely occurs in patients who receive opioids for pain control. If addiction is suspected, it needs to be investigated and diagnosed, if appropriate, but it should not be implied without evidence because this interferes with pain management. The hallmarks of addiction include (1) compulsive use, (2) loss of control of use, and (3) continued use despite risk of harm.

The risk of developing addiction is associated with certain factors, including younger age, personal or family history of substance abuse, and mood disorders. However, the risk of addiction should not prevent health care providers from using opioids to effectively treat moderate to severe acute and chronic pain. Professional organizations and government agencies have issued joint statements about the roles and responsibilities of health care professionals in the appropriate use of opioids for pain management.[37]

TABLE 9-16 MANIFESTATIONS OF OPIOID WITHDRAWAL SYNDROME

	Early Response (6-12 Hr)	Late Response (48-72 Hr)
Psychosocial	• Anxiety	• Excitation
Secretions	• Lacrimation • Rhinorrhea • Diaphoresis	• Diarrhea
Other	• Yawning • Piloerection • Shaking, chills • Dilated pupils • Anorexia • Tremor	• Restlessness • Fever • Nausea and vomiting • Abdominal cramping pain • Hypertension • Tachycardia • Insomnia

DELEGATION DECISIONS

Pain

Effective pain management should be a focus for all members of the nursing team.

Role of Registered Nurse (RN)

- Assess pain characteristics (pattern and onset, area or location, intensity, quality, associated symptoms, and management strategies).
- Develop treatment plan for patient's pain (including drug and nondrug therapies).
- Evaluate whether current treatment plan is effective.
- Teach patient and caregiver about treatment plan.
- Implement discharge teaching about pain management.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Administer ordered pain medications (consider the state nurse practice act and agency policy, since LPNs may not be able to give medications by all routes).
- Assess patient's pain.

Role of Unlicensed Assistive Personnel (UAP)

- Assist with screening for pain and notify RN if patient expresses pain.
- Take and report vital signs before and after pain medications are given.
- Note and report if patient is refusing to participate in ordered activities such as ambulation (since this may indicate inadequate pain management).

TABLE 9-17 PATIENT & CAREGIVER TEACHING GUIDE

Reducing Barriers to Pain Management

When teaching the patient and caregiver about pain management, discuss the following barriers.

Barrier	Nursing Considerations
Fear of addiction	• Explain that addiction is uncommon in patients taking opioids for pain.
Fear of tolerance	• Teach that tolerance is a normal physiologic response to chronic opioid therapy. If tolerance does develop, the drug may need to be changed (e.g., morphine in place of oxycodone). • Teach that there is no absolute upper limit to pure opioid agonists (e.g., morphine). Dosages can be increased, and patient should not save drugs for when the pain is worse. • Teach that tolerance develops more slowly to analgesic effects of opioids than to side effects (e.g., sedation, respiratory depression). Tolerance does not develop to constipation; thus, a regular bowel program should be started early.
Concern about side effects	• Teach methods to prevent and to treat common side effects. • Emphasize that side effects such as sedation and nausea decrease with time. • Explain that different drugs have unique side effects, and other pain drugs can be tried to reduce the specific side effect.
Fear of injections	• Explain that oral medicines are preferred. • Emphasize that even if oral route becomes unusable, transdermal or indwelling parenteral routes can be used rather than injections.
Desire to be "good" patient	• Explain that patients are partners in their care and that the partnership requires open communication of both the patient and the nurse. • Emphasize to patients that they have a responsibility to keep you informed about their pain.
Desire to be stoic	• Explain that although stoicism is a valued behavior in many cultures, failure to report pain can result in undertreatment and severe, unrelieved pain.
Forgetting to take analgesic	• Provide and teach use of pill containers. • Provide methods of record keeping for drug use. • Recruit caregivers to assist with the analgesic regimen.
Concern that pain indicates disease progression	• Explain that increased pain or the need for analgesics may reflect tolerance. • Emphasize that new pain may come from a non–life-threatening source (e.g., muscle spasm, urinary tract infection). • Institute drug and nondrug strategies to reduce anxiety. • Ensure that patient and caregivers have current, accurate, comprehensive information about the disease and prognosis. • Provide psychologic support.
Sense of fatalism	• Explain that pain can be managed in most patients. • Explain that most therapies require a period of trial and error. • Emphasize that side effects can be managed.
Ineffective medication	• Teach that there are multiple options within each category of medication (e.g., opioids, NSAIDs), and another medication from the same category may provide better relief. • Emphasize that finding the best treatment regimen often requires trial and error. • Incorporate nondrug approaches in treatment plan.

Adapted from Ersek M: Enhancing effective pain management by addressing patient barriers to analgesic use, *J Hospice Palliat Nurs* 1:87, 1999.
NSAIDs, Nonsteroidal antiinflammatory drugs.

In addition to the fears about addiction, physical dependence, and tolerance, other barriers hinder effective pain management. Table 9-17 lists some barriers and strategies to address them.

INSTITUTIONALIZING PAIN EDUCATION AND MANAGEMENT

Besides patient and caregiver barriers, other barriers to effective pain management include inadequate health care provider education and lack of organizational support. Traditionally, medical and nursing school curricula have spent little time teaching future physicians and nurses about pain and symptom management. The lack of emphasis on pain in medical and nursing schools has contributed to inadequate training of health care providers.

Progress has been made in overcoming these barriers. Medical and nursing schools now devote more time to addressing pain. Numerous professional organizations have published evidence-based guidelines for assessing and managing pain in many patient populations and clinical settings.

Researchers and health care providers have documented the central role that institutional commitment and practices have in changing clinical practice. Without institutional support, pain outcomes are unlikely to change. One major step in institutionalizing pain management is the development and adoption of The Joint Commission (TJC) guideline on pain.[37] TJC is the accrediting body for most health care facilities (hospitals, nursing homes, and health care clinics). Under these standards, health care facilities are required to (1) recognize the patient's right to appropriate assessment and management of pain; (2) identify pain in patients during their initial assessment and as needed, during ongoing, periodic reassessments; (3) educate health care providers about pain assessment and management and ensure competency; and, (4) educate patients and their families about pain management.

ETHICAL ISSUES IN PAIN MANAGEMENT

Fear of Hastening Death by Administering Analgesics

A common concern of health care professionals and caregivers is that providing sufficient drug to relieve pain will hasten or

precipitate death of a terminally ill person. However, there is no scientific evidence that opioids can hasten death, even among patients at the very end of life. Moreover, as a nurse, you have a moral obligation to provide comfort and pain relief at the end of life. Even if there is a concern about the possibility of hastening death, the rule of double effect provides ethical justification. This rule states that if an unwanted consequence (i.e., hastened death) occurs as a result of an action taken to achieve a moral good (i.e., pain relief), the action is justified if the nurse's intent is to relieve pain and not to hasten death.[38]

Requests for Assisted Suicide

Unrelieved pain is one of the reasons that patients make requests for assisted suicide. Aggressive and adequate pain management may decrease the number of such requests. Assisted suicide is a complex issue that extends beyond pain and pain management. Currently Oregon, Washington, and Montana are the only states where assisted suicide is legal. To address the legal and ethical issues confronting nurses in this unique situation, the Oregon Nurses Association prepared a position paper on this topic.[39]

Use of Placebos in Pain Assessment and Treatment

Placebos are still sometimes used to assess and to treat pain. Using a placebo involves deceiving patients by making them believe that they are receiving an analgesic when in fact they are typically receiving an inert substance such as saline. The use of placebos to assess or treat pain is condemned by several professional organizations.[40]

GERONTOLOGIC CONSIDERATIONS

PAIN

Persistent pain is a common problem in older adults and is often associated with physical disability and psychosocial problems. The prevalence of chronic pain among community-dwelling older adults exceeds 50%, and among older nursing home patients it is approximately 80%. The most common painful conditions among older adults are musculoskeletal conditions such as osteoarthritis and low back pain. Chronic pain often results in depression, sleep disturbance, decreased mobility, increased health care utilization, and physical and social role dysfunction. Despite its high prevalence, pain in older adults is often inadequately assessed and treated.[41]

Several barriers to pain assessment in the older patient exist. Older adults and their health care providers often believe that pain is a normal, inevitable part of aging and that nothing can be done to relieve the pain. Older adults may not report pain for fear of being a "burden" or a "complainer." They may have greater fears of taking opioids than other age-groups. In addition, older patients are more likely to use words such as "aching," "soreness," or "discomfort" rather than "pain." For all these reasons, be persistent in asking older adults about pain. Carry out the assessment in an unhurried, supportive manner.

Another barrier to pain assessment in older adults is the increased prevalence of cognitive, sensory-perceptual, and motor problems that interfere with a person's ability to process information and to communicate. Examples include dementia and delirium, poststroke aphasia, and other communication barriers. Hearing and vision deficits may complicate assessment. Therefore pain assessment tools may need to be adapted for older adults. For example, it may be necessary to use a large-print pain intensity scale. Most older adults, even those with mild to moderate cognitive impairment, can use quantitative scales accurately and reliably.

In older patients with chronic pain, perform a thorough physical examination and history to identify causes of pain, possible therapies, and potential problems. Because depression and functional impairments are common among older adults with pain, they also must be assessed.

Treatment of pain in older adults is complicated by several factors. First, older adults metabolize drugs more slowly than younger people and thus are at greater risk for higher blood levels and adverse effects. The adage "start low and go slow" needs to be applied to analgesic therapy in this age-group. Second, the use of NSAIDs in older adults is associated with a high frequency of GI bleeding. Third, older adults often are taking many drugs for one or more chronic conditions. The addition of analgesics can result in dangerous drug interactions and increased side effects. Fourth, cognitive impairment and ataxia can be exacerbated by analgesics such as opioids, antidepressants, and antiseizure drugs. This requires that health care providers titrate drugs slowly and monitor carefully for side effects.

Treatment regimens for older adults must incorporate nondrug modalities. Exercise and patient teaching are important nondrug interventions for older adults with chronic pain. Also include family and caregivers in the treatment plan (see Table 9-17).

MANAGING PAIN IN SPECIAL POPULATIONS

Patients Unable to Self-Report Pain

Although patient self-report is the gold standard of pain assessment, many illnesses and conditions affect a patient's ability to report pain. These diagnoses and conditions include advanced dementia and other progressive neurologic diseases such as Parkinson's disease and multiple sclerosis, cerebrovascular disease, psychosis, and delirium. For these people, behavioral and physiologic changes may be the only indicators of pain. You must be astute at recognizing behavioral symptoms of pain.

A guide for assessing pain in nonverbal patients is presented in Table 9-18. Several scales have been developed to assess pain-related behaviors in nonverbal patients, particularly those with advanced dementia.[42,43] Several pain assessment tools for people with dementia are available at the City of Hope Pain and Palliative Care Resource Center website (*http://prc.coh.org*).

TABLE 9-18 ASSESSING PAIN IN NONVERBAL PATIENTS

The following assessment techniques are recommended.

- Obtain a self-report when possible (never assume a person is unable to give verbal report).
- Investigate potential causes of pain.
- Observe patient behaviors that indicate pain (e.g., grimacing, frowning, rubbing a painful area, groaning, restlessness).
- Obtain surrogate reports of pain from professional and family caregivers.
- Try to use analgesics and reassess the patient to observe for a decrease in pain-related behaviors.

Source: Position statement from the American Society for Pain Management Nursing (ASPMN). Modified from Herr K, Coyne PJ, Key T, et al: Pain assessment in the nonverbal patient: position statement with clinical practice recommendations, *Pain Manag Nurs* 7:44, 2006.

Patients With Substance Abuse Problems

Health care providers are often reluctant to administer opioids to substance-abusing patients for fear of promoting or enhancing addictions. However, there is no evidence that providing opioid analgesia to these patients in any way worsens their addictive disease. In fact, the stress of unrelieved pain may contribute to relapse in the recovering patient or increased drug use in the patient who is actively abusing drugs.[44]

Guidelines for pain management in patients with addictive disease have been established by the American Society for Pain Management Nursing.[45] These guidelines reflect your role in a team approach in which patients with addictive disease and pain have the right to be treated with dignity, respect, and the same quality of pain assessment and management as all other patients.

If the patient acknowledges opioid use, it is important to determine the types and amounts of drugs used. It is best to avoid exposing the patient to the drug of abuse, and effective equianalgesic doses of other opioids may be determined if daily drug doses are known. If a history of drug abuse is unknown or if the patient does not acknowledge substance abuse, you should suspect abuse when normal doses of analgesics do not relieve the patient's pain.

Aggressive behavior patterns and signs of withdrawal may also occur. Withdrawal symptoms can exacerbate pain and lead to drug-seeking behavior or illicit drug use. Toxicology screens may be helpful in determining recently used drugs. Discussing these findings with the patient may help gain the patient's cooperation in pain control.

Severe pain should be treated with opioids, and at much higher doses than those used with drug-naive patients. The use of a single opioid is preferred. Avoid using a mixed opioid agonist-antagonist such as butorphanol or a partial agonist such as buprenorphine because these drugs may precipitate withdrawal symptoms. Nonopioid and adjuvant analgesics and nondrug pain relief measures may also be used as appropriate. To maintain opioid blood levels and prevent withdrawal symptoms, provide analgesics around the clock. Use supplemental doses to treat breakthrough pain. IV or PCA infusions may be considered for acute pain management.[38]

Pain management for people with addiction is challenging and requires an interdisciplinary team approach. When possible, the team includes pain management and addiction specialists. Team members need to be aware of their own attitudes about people with substance abuse problems, which may result in undertreatment of pain.

CASE STUDY

Pain

Ryan McVay/Photodisc/Thinkstock

Patient Profile

K.C. is a 280-lb (127-kg) 68-year-old African American woman with diabetes who was admitted for an incision and drainage of a right abdominal abscess. She is being discharged on her second postoperative day. Her married daughter will assist with dressing changes at home.

Subjective Data

- Lives alone
- Desires 0 pain but will accept 1 or 2 on a scale of 0 to 10
- Reports incision area pain as a 2 or 3 between dressing changes and as a 6 during dressing changes
- States sharp pain persists 1 to 2 hours after dressing change
- Reports pain between dressing changes controlled by two Percocet tablets
- Has history of fibromyalgia and is complaining of pain "everywhere"

Objective Data

- Requires qid dressing changes after discharge
- For discharge, Percocet (two tablets q4hr for pain PRN) is prescribed

Discussion Questions

1. Describe the assessment data that are important for determining whether K.C. has adequate pain management.
2. How long should the daughter wait after the Percocet is given to begin the dressing change?
3. What additional pain therapies might you plan to help K.C. through the dressing change?
4. ***Priority Decision:*** What are the priority nursing interventions for K.C.?
5. What side effects might she experience because of her pain medication? How can these be managed?
6. ***Delegation Decision:*** To whom can you delegate teaching K.C. and her daughter the plan of care at home?
7. ***Priority Decision:*** Based on the data presented, what are the priority nursing diagnoses? Are there any collaborative problems?
8. ***Evidence-Based Practice:*** K.C.'s daughter asks you if any other strategies could be used to help decrease her mother's incisional pain and her overall fibromyalgia pain.

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Pain is best described as
   - **a.** a creation of a person's imagination.
   - **b.** an unpleasant, subjective experience.
   - **c.** a maladaptive response to a stimulus.
   - **d.** a neurologic event resulting from activation of nociceptors.
2. A patient is receiving a PCA infusion after surgery to repair a hip fracture. She is sleeping soundly but awakens when the nurse speaks to her in a normal tone of voice. Her respirations are 8 breaths/minute. The most appropriate nursing action in this situation is to
   - **a.** stop the PCA infusion.
   - **b.** obtain an oxygen saturation level.
   - **c.** continue to closely monitor the patient.
   - **d.** administer naloxone and contact the physician.

3. Which words are most likely to be used to describe neuropathic pain *(select all that apply)?*
   - **a.** Dull
   - **b.** Mild
   - **c.** Burning
   - **d.** Shooting
   - **e.** Shock-like
4. Unrelieved pain is
   - **a.** expected after major surgery.
   - **b.** expected in a person with cancer.
   - **c.** dangerous and can lead to many physical and psychologic complications.
   - **d.** an annoying sensation, but it is not as important as other physical care needs.
5. A cancer patient who reports ongoing, constant moderate pain with short periods of severe pain during dressing changes is
   - **a.** probably exaggerating his pain.
   - **b.** best treated by referral for surgical treatment of his pain.
   - **c.** best treated by receiving both a long-acting and a short-acting opioid.
   - **d.** best treated by regularly scheduled short-acting opioids plus acetaminophen.
6. An example of distraction to provide pain relief is
   - **a.** TENS.
   - **b.** music.
   - **c.** exercise.
   - **d.** biofeedback.
7. Appropriate nonopioid analgesics for mild pain include *(select all that apply)*
   - **a.** oxycodone.
   - **b.** ibuprofen (Advil).
   - **c.** lorazepam (Ativan).
   - **d.** acetaminophen (Tylenol).
   - **e.** codeine with acetaminophen (Tylenol #3).
8. An important nursing responsibility related to pain is to
   - **a.** leave the patient alone to rest.
   - **b.** help the patient appear to not be in pain.
   - **c.** believe what the patient says about the pain.
   - **d.** assume responsibility for eliminating the patient's pain.
9. Providing opioids to a dying patient who is experiencing moderate to severe pain
   - **a.** may cause addiction.
   - **b.** will probably be ineffective.
   - **c.** is an appropriate nursing action.
   - **d.** will likely hasten the person's death.
10. A nurse believes that patients with the same type of tissue injury should have the same amount of pain. This statement reflects
    - **a.** a belief that will contribute to appropriate pain management.
    - **b.** an accurate statement about pain mechanisms and an expected goal of pain therapy.
    - **c.** a belief that will have no effect on the type of care provided to people in pain.
    - **d.** a lack of knowledge about pain mechanisms, which is likely to contribute to poor pain management.

1. b, 2. c, 3. c, d, e, 4. c, 5. c, 6. b, 7. b, d, 8. c, 9. c, 10. d.

LEARNING OUTCOMES

1. Discuss the purpose of palliative care.
2. Describe the purpose of and services provided by hospice.
3. Describe the physical and psychologic manifestations at the end of life.
4. Explain the process of grief and bereavement at the end of life.
5. Describe the nursing management for the dying patient.
6. Examine the cultural and spiritual issues related to end-of-life care.
7. Discuss ethical and legal issues in end-of-life care.
8. Explore the special needs of family caregivers in end-of-life care.
9. Discuss the special needs of the nurse who cares for dying patients and their families.

PALLIATIVE CARE

Palliative care is any form of care or treatment that focuses on reducing the severity of disease symptoms, rather than trying to delay or reverse the progression of the disease itself or provide a cure. The overall goals of palliative care are to (1) prevent and relieve suffering and (2) improve quality of life for patients with serious, life-limiting illnesses (Fig. 10-1). Specific goals of palliative care are listed in Table 10-1.

Palliative care originated as end-of-life (EOL) care in the 1960s. Initially this care focused on providing the relief of symptoms and emotional support to the patient, family, and significant others during the terminal phase of a serious life-limiting disease. Now that phase of palliative care is called palliative care at end-of-life, which is the focus of this chapter. Since its beginning, the scope of palliative care has greatly expanded. Now palliative care focuses on maintaining and improving the quality of life for all patients and their families during any stage of a life-limiting illness, whether acute, chronic, or terminal.

According to the World Health Organization (WHO), palliative care is an approach that improves the quality of life of patients and their families who face problems associated with life-threatening illness. Palliative care aims to prevent and relieve suffering by early identification, assessment, and treatment of pain and other types of physical, psychologic, emotional, and spiritual distress.[1] Ideally, all patients receiving curative or restorative health care should receive palliative care concurrently. Palliative care extends into the period of EOL care; bereavement care follows the patient's death[2] (Fig. 10-2).

To optimize the benefits of palliative care, it should be initiated after a person receives a diagnosis of a life-limiting

TABLE 10-1 GOALS OF PALLIATIVE CARE

- Provide relief from symptoms, including pain.
- Regard dying as a normal process.
- Affirm life and neither hasten nor postpone death.
- Support holistic patient care and enhance quality of life.
- Offer support to patients to live as actively as possible until death.
- Offer support to the family during the patient's illness and in their own bereavement.

illness, such as cancer, heart failure, chronic obstructive pulmonary disease, dementia, or end-stage kidney disease. Ideally, the palliative care team is an interdisciplinary collaboration involving physicians, social workers, pharmacists, nurses, chaplains, and other health care professionals. Communication among the patient, family, and palliative health care team is important to provide optimal care. Patients receive palliative care services in the home and in long-term and acute care facilities. More recently, emergency departments and intensive care units (ICUs) have integrated palliative care into the delivery of care. Many institutions have established interdisciplinary palliative and hospice care teams.[3]

HOSPICE CARE

Palliative care often includes hospice care before or at the end of life (Fig. 10-3). **Hospice** is not a place but a concept of care that provides compassion, concern, and support for the dying (Fig. 10-4). Hospice exists to provide support and care for persons in the last phases of a terminal disease so that they might live as fully and as comfortable as possible. Hospice programs provide care with an emphasis on symptom management, advance care planning, spiritual care, and family support.[4]

The major difference between palliative care and hospice care is that palliative care allows a person to simultaneously receive curative and palliative treatments. Hospice care is provided once a person decides to forgo curative treatments.

Approximately 1.5 million patients every year receive services through hospice programs. About 42% of the patients who die in the United States are under the care of a hospice program.[5] More than a third of all hospice patients are 85 years of age or older, and 83% are over 65. Of these patients, the most common diagnosis is cancer. Eighty percent of patients using hospice services are white.[5] Currently the median length of stay in a hospice program is 21 days.

Hospice programs are organized under a variety of models. Some are hospital-based programs, others are part of existing home health care agencies, and others are freestanding or community-based programs. However, regardless of their organization, all hospices emphasize palliative rather than curative care, and quality rather than quantity of life.

Hospice care is provided in a variety of locations, including the home, inpatient settings, and long-term care facilities. Hospice care can be on a part-time, intermittent, on-call, regularly scheduled, or continuous basis. Hospice services are available 24 hours a day, 7 days a week to provide help to patients and families in their homes. The inpatient hospice settings have been deinstitutionalized to make the atmosphere as relaxed and homelike as possible (Fig. 10-5). Staff and volunteers are available for the patient and the family.

A medically supervised interdisciplinary team of professionals and volunteers provides holistic hospice services. The hospice nurse plays a pivotal role in coordination of the hospice team.[6] Hospice nurses work collaboratively with hospice physicians, pharmacists, dietitians, physical therapists, social workers, cer-

FIG. 10-5 Inpatient hospice settings have been deinstitutionalized to make the atmosphere as relaxed and homelike as possible. (Photodisc/Thinkstock)

tified nursing assistants, chaplains and other clergy, and volunteers to provide care and support to the patient and the family. Hospice nurses are educated in pain control and symptom management, spiritual assessment, and assessment and management of family needs. To meet patient and family needs, hospice nurses need excellent teaching skills, compassion, flexibility, cultural competence, and adaptability.

The decision to begin hospice care is difficult for several reasons. Frequently patients, families, physicians, and other health care providers lack information about hospice care. Some cultural/ethnic groups may underutilize hospice because of lack of awareness of hospice services, desire to continue with potentially curative therapies, and concerns about lack of minority hospice workers.[7] Physicians may be reluctant to give referrals because they sometimes view a patient's decline as their personal failure. Some patients or family members see it as giving up.

Admission to a hospice program has two criteria. The first criterion is that the patient must desire the services and agree in writing that only hospice care (and not curative care) can be used to treat the terminal illness. Patients in hospice programs can withdraw from the program at any time (e.g., if their condition unexpectedly improves). Patients can receive care for other health problems that begin after starting hospice.

The second criterion is that the patient must be considered eligible for hospice. Medicare, Medicaid, and other insurers require that two physicians certify that the patient's prognosis is terminal, with less than 6 months to live. It is important to realize that the physician who certified that a hospice patient is terminal does not "guarantee" death within 6 months. Indeed, if a patient in hospice survives beyond 6 months, Medicare and other reimbursement organizations will continue to reimburse for more extended periods of treatment if the patient still meets enrollment criteria. After this initial certification, only one physician (e.g., the hospice medical director) is needed to recertify the patient.

DEATH

Death occurs when all vital organs and body systems cease to function. It is the irreversible cessation of cardiovascular, respiratory, and brain function.

Brain death is an irreversible loss of all brain functions, including those of the brainstem. Brain death is a clinical diagnosis, and it can be made in patients whose hearts continue to beat and who are maintained on mechanical ventilation in the ICU.[8] Brain death occurs when the cerebral cortex stops functioning or is irreversibly destroyed.

Since the development of technology that assists in supporting life, controversies have arisen over the exact definition of death. Questions and discussions have focused on whether brain death occurs when the whole brain (cortex and brainstem) ceases activity or when function of the cortex alone stops. In 1995 the Quality Standards Subcommittee of the American Academy of Neurology recommended diagnostic criteria guidelines for clinical diagnosis of brain death.[9] These criteria for brain death include coma or unresponsiveness, absence of brainstem reflexes, and apnea. Specific assessments by a physician are required to validate each of the criteria.[8,9]

Currently, legal and medical standards require that all brain function must cease for brain death to be pronounced and life support to be disconnected. Diagnosis of brain death is of particular importance when organ donation is an option. In some states and under specific circumstances, registered nurses are legally permitted to pronounce death. Policies and procedures may vary from state to state and among health care institutions.

END-OF-LIFE CARE

End of life generally refers to the final phase of a patient's illness when death is imminent. The time from diagnosis of a terminal illness to death varies considerably, depending on the patient's diagnosis and extent of disease.

The Institute of Medicine defines *end of life* as the period during which an individual copes with declining health from a terminal illness or from the frailties associated with advanced age, even if death is not clearly imminent.[10] In some cases it is obvious to health care providers that the patient is at the end of life, but in other cases they may be uncertain if the end is close at hand. This uncertainty adds to the challenge of answering common questions the patient and family may ask, such as "How much time is left?"

End-of-life care (EOL care) is the term used for issues and services related to death and dying. EOL care focuses on physical and psychosocial needs for the patient and the patient's family. The goals for EOL care are to (1) provide comfort and supportive care during the dying process, (2) improve the quality of the patient's remaining life, (3) help ensure a dignified death, and (4) provide emotional support to the family.

Physical Manifestations at End of Life

As death approaches, metabolism is reduced and the body gradually slows down until all functions end. Respiratory changes are common at the end of life. Respirations may be rapid or slow, shallow, and irregular. Breath sounds may become wet and noisy, both audibly and on auscultation. Noisy, wet-sounding respirations, termed the **death rattle,** are caused by mouth breathing and accumulation of mucus in the airways. **Cheyne-Stokes respiration** is a pattern of breathing characterized by

TABLE 10-2 PHYSICAL MANIFESTATIONS AT END OF LIFE

System	Manifestations
Sensory system	
Hearing	• Usually last sense to disappear
Touch	• Decreased sensation • Decreased perception of pain and touch
Taste and smell	• Decreased with disease progression
Sight	• Blurring of vision • Sinking and glazing of eyes • Blink reflex absent • Eyelids remain half-open
Cardiovascular system	• Increased heart rate; later slowing and weakening of pulse • Irregular rhythm • Decreased blood pressure • Delayed absorption of drugs administered intramuscularly or subcutaneously
Respiratory system	• Increased respiratory rate • Cheyne-Stokes respiration (pattern of respiration characterized by alternating periods of apnea and deep, rapid breathing) • Inability to cough or clear secretions resulting in grunting, gurgling, or noisy congested breathing (death rattle) • Irregular breathing, gradually slowing down to terminal gasps (may be described as guppy breathing)
Urinary system	• Gradual decrease in urine output • Incontinence of urine • Inability to urinate
Gastrointestinal system	• Slowing or cessation of GI function (may be enhanced by pain-relieving drugs) • Accumulation of gas • Distention and nausea • Loss of sphincter control, producing incontinence • Bowel movement before imminent death or at time of death
Musculoskeletal system	• Gradual loss of ability to move • Sagging of jaw resulting from loss of facial muscle tone • Difficulty speaking • Swallowing becoming more difficult • Difficulty maintaining body posture and alignment • Loss of gag reflex • Jerking seen in patients on large amounts of opioids
Integumentary system	• Mottling on hands, feet, arms, and legs • Cold, clammy skin • Cyanosis of nose, nail beds, knees • "Waxlike" skin when very near death

alternating periods of apnea and deep, rapid breathing. When respirations cease, the heart stops beating within a few minutes. The physical manifestations of approaching death are listed in Table 10-2.

Psychosocial Manifestations at End of Life

A variety of feelings and emotions can affect the dying patient and family at the end of life (Table 10-3). Most patients and families struggle with a terminal diagnosis and the realization that there is no cure. The patient and the family may feel overwhelmed, fearful, powerless, and fatigued. The family's response

TABLE 10-3 PSYCHOSOCIAL MANIFESTATIONS AT END OF LIFE

- Altered decision making
- Anxiety about unfinished business
- Decreased socialization
- Fear of loneliness
- Fear of meaninglessness of one's life
- Fear of pain
- Helplessness
- Life review
- Peacefulness
- Restlessness
- Saying goodbyes
- Unusual communication
- Vision-like experiences
- Withdrawal

TABLE 10-4 KÜBLER-ROSS MODEL OF GRIEF

Stage	What Person May Say	Characteristics
Denial	No, not me. It cannot be true.	Denies the loss has taken place and may withdraw. This response may last minutes to months.
Anger	Why me?	May be angry at the person who inflicted the hurt (even after death) or at the world for letting it happen. May be angry with self for letting an event (e.g., car accident) take place, even if nothing could have stopped it.
Bargaining	Yes me, but…	May make bargains with God, asking "If I do this, will you take away the loss?"
Depression	Yes me, and I am sad	Feels numb, although anger and sadness may remain underneath.
Acceptance	Yes me, but it is okay	Anger, sadness, and mourning have tapered off. Accepts the reality of the loss.

Adapted from Kübler-Ross E: *On death and dying,* New York, 1969, Macmillan. (Classic)

depends in part on the type and length of the illness and their relationship with the person.

The patient's needs and wishes must be respected. Patients need time to think and express their feelings. Response time to questions may be sluggish because of fatigue, weakness, and confusion.

Bereavement and Grief

Although the terms are often used interchangeably, *bereavement* refers to the state of loss, and *grief* refers to the reaction to loss. **Bereavement** is the period following the death of a loved one during which grief is experienced and mourning occurs. The time spent in bereavement depends on a number of factors, including how attached one was to the person who died and how much time was spent anticipating the loss.

Grief is a normal reaction to loss. Grief occurs in response to the real loss of a loved one and the loss of what might have been. Grief is dynamic and includes both psychologic and physiologic responses following a loss. Psychologic responses include anger, guilt, anxiety, sadness, depression, and despair. Physiologic reactions include sleeping problems, changes in appetite, physical problems, and illness.

Grief is a powerful emotional state that affects all aspects of a person's life. It is a complex and intense emotional experience. In the Kübler-Ross model of grief, there are five stages[11,12] (Table 10-4). Not every person experiences all the stages of grieving,

and they are not always progressive in order. It is common to reach a stage and then go backward. For example, a person may have reached the stage of bargaining, and then revert back to the denial or anger stage.

Another model of grief is the grief wheel (Fig. 10-6). After a person experiences the loss, he or she feels *shock* (numbness, denial, inability to think straight). Then comes the *protest* stage where a person experiences anger, guilt, sadness, fear, and searching. Then comes the *disorganization* stage where a person feels despair, apathy, anxiety, and confusion. The next stage is *reorganization* where a person gradually returns to normal functioning, but he or she feels different. The final stage is the *new normal*. Eventually the destabilization experienced in grief resolves and a normal state can began. However, because of the loss, the normal state is not the same as before. The challenge is to accept the new normal. Trying to go back to the "old" normal (which is not there anymore) is what causes a great deal of anxiety and stress.

The manner in which a person grieves depends on factors such as the relationship with the person who has died (e.g., spouse, parent), physical and emotional coping resources, concurrent life stresses, cultural beliefs, and personality. Additional factors that affect the grief response include mental and physical health, economic resources, religious influences or spiritual beliefs, family relationships, social support, and time spent preparing for the death. Issues that occurred before the death (e.g., marital problems) may affect the grief response.[13]

The grief experience for the caregiver of the patient with a chronic illness often begins long before the actual death event. This is called *anticipatory grief*. Patients at the end of life can also experience anticipatory grief.

Working in a positive way through the grief process helps to adapt to the loss.[14] Grief that assists the person in accepting the reality of death is called *adaptive grief,* which is a healthy response. It may be associated with grieving before a death actually occurs or when the inevitability of the death is known. Indicators of adaptive grief include the ability to see some good resulting from the death and positive memories of the deceased person.

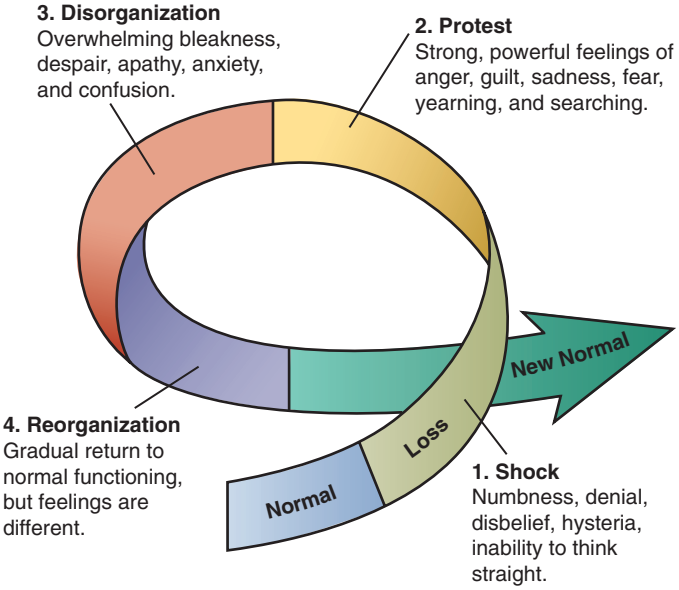

FIG. 10-6 The grief wheel model begins with the normal state at the bottom. After a person goes through the grief process, eventually the grief will resolve. However, because of the loss, the normal state is not the same as before. The challenge is to accept the "new normal." (Adapted from Powell TJ: *Stress-free living,* Dorling Kindersley Ltd 2000. © Dorling Kindersley Ltd.)

Dysfunctional reactions to loss can occur, and the physical and psychologic impact of the loved one's death may persist for years. *Prolonged grief disorder,* formerly called *complicated grief,* is a term used to describe prolonged and intense mourning. Prolonged grief disorder can include symptoms such as recurrent and severe distressing emotions and intrusive thoughts related to the loss of a loved one, self-neglect, and denial of the loss for longer than 6 months. Bereaved individuals with prolonged grief disorder may feel "stuck" and unable to move forward after the death of a loved one. It is estimated that one in five bereaved individuals experiences prolonged grief disorder. Those who experience prolonged grief disorder are at great risk for illness and have work and social impairments. Some studies suggest that prolonged grief disorder is less likely to occur after deaths in hospice compared with those in acute care settings.[15]

Bereavement and grief counseling is an important aspect of palliative care. The goal of a bereavement program is to provide support and to assist survivors in the transition to a life without the deceased person. Incorporate grief support into the plan of care for the family and significant others during the patient's illness and after the death.

Priority interventions for grief must focus on providing an environment that allows the patient and the family to express their feelings such as anger, fear, and guilt. Discussion of feelings helps both the patient and the family work toward resolution of the grief process. Respect for the patient's privacy and need or desire to talk (or not to talk) is important. Honesty in answering questions and giving information is essential.

Spiritual Needs

Assessment of spiritual needs in EOL care is a key consideration (Table 10-5). Spiritual needs do not necessarily equate to religion. **Spirituality** is defined as those beliefs, values, and practices that relate to the search for existential meaning and purpose and that may or may not include a belief in a higher power.[16] A person may not be part of a particular religion but have a deep spirituality. Many times at the end of life, patients question their beliefs about a higher power, their journey through life, religion, and an afterlife (Fig. 10-7). Some patients may choose to pursue

TABLE 10-5 SPIRITUAL ASSESSMENT

1. Who or what provides you strength and hope?
2. Do you use prayer in your life?
3. How do you express spirituality?
4. How would you describe your philosophy of life?
5. What type of spiritual or religious support do you desire?
6. What is the name of your clergy, minister, chaplain, pastor, rabbi?
7. What does suffering mean to you?
8. What does dying mean to you?
9. What are your spiritual goals?
10. Is there a role of church/synagogue in your life?
11. Has belief in God been important in your life?
12. How does your faith help you cope with illness?
13. How do you keep going day after day?
14. What helps you get through this health care experience?
15. How has illness affected you and your family?

FIG. 10-7 Spiritual needs are an important consideration in end-of-life care. (Photodisc/Thinkstock)

a spiritual path. Some may not. Respect an individual's choice. Assess the patient's and the family's preferences related to spiritual guidance or pastoral care services and make appropriate referrals.[16]

Deep-seated spiritual beliefs may surface for some patients when they deal with their terminal diagnosis and related issues. Spiritual distress may occur.[17] Characteristics of spiritual distress include anger toward God or a higher being, change in behavior and mood, desire for spiritual assistance, or displaced anger toward clergy.[16]

Spirituality has been associated with decreased despair in patients at the end of life. Some dying patients are secure in their faith about the future. It is common to observe patients relinquishing material possessions of life and focusing on values that they believe will lead them on to another place. Many turn to religion because it may provide order to the world even in the presence of physical decline, social losses, suffering, and impending death. Religion may offer an existential meaning that offers a sense of peace and recognition of one's place in the broader cosmic context.[17]

CULTURALLY COMPETENT CARE

END OF LIFE

Culture and ethnicity should be considered throughout the EOL process. Cultural beliefs affect a person's understanding of and reaction to death or loss. In some cultural/ethnic groups, death and dying are private matters shared only with significant others. Often feelings are repressed or internalized. People who believe in "toughing it out" or "being strong" may not express themselves when they are experiencing a loss. Some cultural groups, such as African Americans and Hispanic/Latinos, may easily express their feelings and emotions. Kinship tends to be strong in the Hispanic culture, and both immediate and extended family provide support for one another. Expressing feelings of loss is encouraged and accepted easily.[18,19]

If palliative or hospice care is recommended, some cultural/ethnic groups are less likely to use these resources. For example, African Americans use hospice care less often because they value "toughness" in times of hardship and rely on God.[18] For Hispanics, often spouses and daughters need to be involved in decisions regarding palliative care and hospice.[20]Consider patient attitudes toward death and suffering and preferences for information. The decision to use palliative care or hospice services may be perceived as "giving up" or receiving second-rate care. Such attitudes are best approached through clear, open discussions with the patient and the family about the philosophy and services of palliative and hospice organizations.[18-21] Culture and ethnicity affect decision making with regard to life support and withholding and withdrawing of treatments.[22] In some cultures, such as the Filipino American culture, it may be appropriate to first discuss a terminal diagnosis with the family before informing the patient.

Rituals associated with dying are part of all cultures.[18] In certain cultures the family may want to keep constant vigil in the room of a dying patient or in the waiting area. For example, some Jewish Americans believe that the spirit should not be alone when it leaves the body at the time of death. Therefore someone who is terminally ill should never be left alone. The Jewish culture believes all body tissues must be buried with the individual. Once a death has occurred, some cultures, such as the Puerto Rican American culture, may want to kiss and touch the body to say goodbye.

Families with non–English-speaking members are at risk for receiving less information about their family member's critical illness and prognosis.[23] Cultural variations also exist in symptom expression (e.g., pain expression) and use of health care services. Providing culturally competent care requires assessment of nonverbal cues such as grimaces, body position, and decreased or guarded movements. Issues related to pain assessment and management are discussed in Chapter 9.

Differences among cultural beliefs and values in relation to death and dying are innumerable. Nursing assessment of beliefs and preferences should be made on an individual basis to avoid stereotyping individuals with different cultural belief systems. This includes assessing and documenting the patient's cultural background, concerns, health practices, and attitudes about suffering. Early in the assessment, ask the patient and family to describe their desires for care before death and care of the body after death. Use open-ended questions related to the patient's perspectives on his or her illness and the patient's expectations of care. Use this assessment to guide the patient's plan of care and evaluation. You can also suggest or plan grief and bereavement counseling for the family. At the same time, accommodations need to be made related to the patient's language, diet, and cultural beliefs and practices. When appropriate, access medical interpreter services so that the patient's wishes are known. (Culturally competent care is discussed in Chapter 2.)

LEGAL AND ETHICAL ISSUES AFFECTING END-OF-LIFE CARE

Patients and families struggle with many decisions during the terminal illness and dying experience. Many people decide that the outcomes related to their care should be based on their own wishes and values. It is important to provide information to assist patients with these decisions. The decisions may involve the choice for (1) organ and tissue donations, (2) advance directives (e.g., medical power of attorney, living wills), (3) resuscitation, (4) mechanical ventilation, and (5) feeding tube placement.

Organ and Tissue Donation

Persons who are legally competent may choose organ donation. Any body part or the entire body may be donated. The decision to donate organs or to provide anatomic gifts may be made by a person before death or by immediate family after death. Family permission must be obtained at the time of donation.[24]

Some people carry donor cards. Some states allow organ donation to be marked on drivers' licenses. The names of agencies that handle organ donation vary by state and community. Common names for such an agency might be the organ bank, organ-sharing network, and organ-sharing alliance. Both organ and tissue donations follow specific legal guidelines. Legal requirements and facility policies for organ or tissue donation must be followed. The physician must be notified immediately when organ donation is intended because some tissues must be used within hours after death.

Advance Care Planning and Advance Directives

Advance care planning is a process that involves having patients (1) think through their values and goals for treatment, (2) talk about their values and goals with others, and (3) document them. **Advance directives** are the written documents that provide information about the patient's wishes and his or her designated spokesperson (Table 10-6).

The first advance directive was known by laypersons as a *living will.* Most states have replaced the idea of living wills with *natural death acts,* which may include *directives to physicians* (DTPs), *durable power of attorney for health care* (DPAHC), and *medical power of attorney* (MPOA). Under the natural death acts, an individual can tell the physician exactly what treatment is or is not desired. Each state has its own unique requirements. Keep in mind that patients often change their minds about desired treatments as their disease state progresses. Therefore it is important to reassess a patient's advance directives. For cognitively impaired older adults, consider the person's values and manner of life to make health care decisions consistent with decisions they made when they were cognitively intact.

Copies of state-specific forms can be obtained from local medical associations and on the Internet. However, a person may write his or her wishes without special forms. Verbal directives may be given to physicians with specific instructions in the presence of two witnesses. Attorneys and notaries may not be required. If the person is not capable of communicating his or her wishes, the surrogate decision maker (most often family or significant other) determines the measures that will or will not be taken. The physician and the nurse can discuss the options that are available with the family. Then it is important to document the family's decision.

Resuscitation

Cardiopulmonary resuscitation (CPR) has become common practice in health care. Patients who have respiratory or cardiac arrest are given CPR unless a *do-not-resuscitate (DNR) order* is given by the physician. A DNR order is a written medical order that documents a patient's wishes regarding resuscitation and, more important, the patient's desire to avoid CPR.[25]

The patient or the patient's family has the right to decide whether CPR will be used. It is no longer the sole decision of the physician. The American Nurses Association (ANA) supports the patient's right to self-determination and believes that nurses have a primary role in supporting the patient and family's decisions.[26]

A physician's order should be written concerning the patient's or family's wishes for the use of CPR. Several different types of CPR decisions can be made. Complete and total heroic measures, which may include CPR, drugs, and mechanical ventilation, can be referred to as a *full code.* Some people choose variations of the full code. A *chemical code* involves the

TABLE 10-6 COMMON DOCUMENTS USED IN END-OF-LIFE CARE

Document	Description	Special Considerations
Advance directive	General term used to describe documents that give instructions about future medical care and treatments and who should make the decisions in the event the person is unable to communicate.	• Should comply with guidelines established by state of residence.
Directive to physicians	Written document specifying the patient's wish to be allowed to die without heroic or extraordinary measures.	• Indicates specific measures to be used or withheld.
Do not resuscitate (DNR)	Written physician's order instructing health care providers not to attempt CPR. DNR order often requested by family. Must be signed by a physician to be valid.	• Must indicate any specific measures to be used or withheld.
Durable power of attorney for health care	Term used by some states to describe a document used for listing the person(s) to make health care decisions should a patient become unable to make informed decisions for self.	• May be the same as medical power of attorney. • Indicates specific measures to be used or withheld.
Living will	Lay term used to describe any documents that give instructions about future medical care and treatments or the wish to be allowed to die without heroic or extraordinary measures should the patient be unable to communicate for self.	• Must identify specific treatments that a person wants or does not want at end of life.
Medical power of attorney	Term used by some states to describe a document used for listing the person(s) to make health care decisions should a patient become unable to make informed decisions for self.	• May be the same as durable power of attorney for health care, health care proxy, or appointment of a health care agent or surrogate. Specifies measures to be used or withheld. • Person appointed may be called a health care agent, surrogate, attorney-in-fact, or proxy.

CPR, Cardiopulmonary resuscitation.

use of drugs for resuscitation without the use of CPR. A "no code," or a DNR order, allows the person to die with comfort measures only and without the interference of technology. Some states have implemented a form called *out-of-hospital DNR* for use by terminally ill patients who wish to have no heroic measures used to prolong life after they leave an acute care facility.[27,28]

Allow natural death (AND) is a term being used to replace "no code" or DNR.[28] This term more accurately conveys what actually happens. It is also sometimes referred to as *"comfort measures only"* status, meaning that all comfort measures associated with pain control and symptom management are carried out, but the natural physiologic progression to death is not delayed or interrupted.

Withholding or withdrawing treatments must be included in an advance directive. The directive must clearly state what is to be done and what is not to be done. The ANA position statement on foregoing nutrition and hydration states that the decision to withhold artificial nutrition and hydration should be made by the patient or surrogate with the health care team.[26] For patients who are no longer receiving artificial nutrition and hydration, it is important to continue to provide expert nursing care.

Euthanasia is the deliberate act of hastening death. The ANA statement on active euthanasia states that the nurse should not participate in active euthanasia because such an act is in direct violation of the Code for Nurses, the ethical traditions and goals of the profession, and its covenant with society. As a nurse, you have an obligation to provide timely, humane, comprehensive, and compassionate EOL care.

You need to be aware of legal issues and the patient's wishes. Advance directives and organ donor information should be located in the medical record and identified on the patient's record and/or the nursing care plan. All caregivers responsible for the patient need to know the patient's wishes. Additionally, you are responsible for becoming familiar with state, local, and agency procedures in EOL care documentation.

ETHICAL/LEGAL DILEMMAS

End-of-Life Care

Situation

A.P., a terminally ill 50-year-old woman with metastatic breast cancer, has developed severe bone pain that is not adequately controlled by her present dose of IV morphine. She moans at rest and verbalizes severe pain from any movement to reposition her. At the team conference the nurses discuss the need for more effective pain control, but are concerned that additional pain medicine could hasten her death.

Ethical/Legal Points for Consideration

- Adequate pain relief is an important outcome for all patients, especially patients who are terminally ill. The *principle of beneficence* means that care is provided to benefit patients. The goal of adequate pain control in the terminally ill to alleviate suffering is based on the *principle of nonmaleficence:* preventing or reducing harm to the patient. The secondary effect of hastening the patient's death is ethically justified; this is known as the concept of *double effect.*
- Legally, the *standard of care* is used to define the nursing acts that are required for safe and competent nursing practice. When the actual nursing care falls below the standard of care, it is considered negligent and unsafe, and the nurse is at risk for being found incompetent.
- In a court of law the standard of care in nursing is determined by nursing experts and evidence-based practices. The increasing use of technology to access the latest scientific findings is changing the standard of nursing care to a national, if not global, standard defined by research findings and nationally recognized expert testimony.
- In this situation the standard of care is that the patient will experience pain relief. Failure of the nurse to act assertively to achieve pain relief for the patient and failure to effectively use resources to obtain that pain relief will be considered below the standard of care and unsafe and incompetent practice.

Discussion Questions

1. What types of discussions need to occur among the health care team, patient, and family as the terminally ill patient approaches this phase of care?
2. Distinguish between promotion of comfort and relief of pain in dying patients, and between assisted suicide and euthanasia. (Use the American Nurses Association position statements at www.ana.org.)

NURSING MANAGEMENT END OF LIFE

Nurses spend more time with patients near the end of life than any other health care professionals. Nursing care of terminally ill and dying patients is holistic and encompasses all psychosocial and physical needs. Respect, dignity, and comfort are important for the patient and the family. In addition, you need to recognize your own needs when dealing with grief and dying.

NURSING ASSESSMENT

Assessment of the terminally ill or dying patient varies with the patient's condition. Be sensitive and do not impose repeated, unnecessary assessments on the dying patient. When possible, use health history data that are available in the medical record rather than tiring the patient with an interview.

Document the specific event or change that brought the patient into the health care setting. Record the patient's medical diagnoses, medication profile, and allergies.

If the patient is alert, do a brief review of the body systems to detect important signs and symptoms. Assess for discomfort, pain, nausea, and dyspnea so that prompt interventions can be implemented. In addition, evaluate and manage co-morbidities or acute episodes of problems such as diabetes mellitus or headache. Elicit information about the patient's abilities, food and fluid intake, patterns of sleep and rest, and response to the stress of terminal illness. Assess the patient's ability to cope with the diagnosis and prognosis of the illness. Also determine the family's capacity to manage the needed care and to cope with the illness and its consequences.

The physical assessment is abbreviated and focuses on changes that accompany terminal illness and the specific disease process.[29] The frequency of assessment depends on the patient's stability, but assessment is done at least every 8 hours in the institutional setting. For patients cared for in their homes by hospice programs, assessment may occur weekly. As changes occur, assessment and documentation may need to be done more frequently. If the patient is in the final hours of life, the physical assessment may be limited to essential data.

Key elements of a social assessment include determining the relationships and patterns of communication among the family. If multiple family members are present, listen to varying concerns from different members. Differences in expectations and interpersonal conflict can result in family disruptions after the death of the loved one. Social assessment also includes evaluating the goals of the patient and the family.

As death approaches, monitor the patient for multiple systems that often are failing during the EOL period. This requires vigilance and attention to physical changes that are often subtle. Neurologic assessment is especially important and includes level of consciousness, presence of reflexes, and pupil responses. Evaluation of vital signs, skin color, and temperature indicates changes in circulation. Monitor and describe respiratory status, character and pattern of respirations, and characteristics of breath sounds. Monitor nutritional and fluid intake, urine output, and bowel function, since this provides assessment data for renal and gastrointestinal functioning. Assess skin condition on an ongoing basis because skin becomes fragile and may easily break down.

PLANNING

Planning and coordinating care at EOL must focus on the needs of the patient, family, and significant others. In some cases a family conference may be helpful to develop a coordinated plan of care.

Develop a comprehensive plan to support, teach, and evaluate patients and families. Nursing care goals during the last stages of life involve comfort measures and care of the patient's emotional and physical needs. These goals may also include determining where the patient would like to die and whether this is possible. For example, the patient may want to die at home, but the family may object.

The last hours or days of the patient experiencing brain death are frequently spent in the ICU. Planning for EOL care may be particularly challenging in the ICU environment. At this time, some families are approached about organ donation. Consultation from palliative care specialists may help the family plan and cope with EOL issues.

NURSING IMPLEMENTATION

Psychosocial care and physical care are interrelated for both the dying patient and family. Teaching them is an important part of EOL care. Families need ongoing information on the disease, the dying process, and any care that will be provided. They need information on how to cope with the many issues during this period of their lives. Denial and grieving may be barriers to learning and understanding at the end of life for both the patient and family.

PSYCHOSOCIAL CARE. As death approaches, respond appropriately to the patient's psychosocial manifestations at the end of life (Table 10-7).

Anxiety and Depression. Patients often exhibit signs of anxiety and depression during the EOL period. Anxiety is an uneasy feeling whose cause is not easily identified. Anxiety is frequently related to fear.

Causes of anxiety and depression may include uncontrolled pain and dyspnea, psychosocial factors related to the disease process or impending death, altered physiologic states, and drugs used in high dosages. Encouragement, support, and teaching decrease some of the anxiety and depression. Management of anxiety and depression may include both medications and nonpharmacologic interventions. Relaxation strategies such as relaxation breathing, muscle relaxation, music, and imagery may be useful (see Chapter 7).

Anger. Anger is a common and normal response to grief. A grieving person cannot be forced to accept the loss. The surviving family members may be angry with the dying loved one who is leaving them. Encourage the expression of feelings, but at the same time realize how difficult it is to come to terms with loss. As a nurse, you may be the target of the anger. You need to understand what is happening and not react on a personal level.

TABLE 10-7 NURSING ASSESSMENT

Psychosocial Care at End of Life

Characteristic	Nursing Management
Withdrawal	
Patient near death may seem withdrawn from the physical environment, maintaining the ability to hear but unable to respond.	Converse as though the patient were alert, using a soft voice and gentle touch.
Unusual Communication	
This may indicate that an unresolved issue is preventing the dying person from letting go. Patient may become restless and agitated or perform repetitive tasks (may also indicate terminal delirium).	Encourage the family to talk with and reassure the dying person.
Vision-like Experiences	
Patient may talk to persons who are not there or see places and objects not visible. Vision-like experiences assist the dying person in coming to terms with meaning in life and transition from it.	Affirm the dying person's experience as a part of transition from this life.
Saying Goodbyes	
It is important for the patient and family to acknowledge their sadness, mutually forgive one another, and say goodbye.	Encourage the dying person and family to verbalize their feelings of sadness, loss, forgiveness; to touch, hug, cry. Allow the patient and family privacy to express their feelings and comfort one another.
Spiritual Needs	
Patient or family may request spiritual support such as the presence of a chaplain.	Encourage visit by appropriate spiritual care service provider, chaplain, or family member. Allow patient to express his or her spiritual needs.

Hopelessness and Powerlessness. Feelings of hopelessness and powerlessness are common at the EOL. Encourage realistic hope within the limits of the situation. Allow the patient and the family to deal with what is within their control, and help them to recognize what is beyond their control. When possible, support the patient's involvement in decision making about care to foster a sense of control and autonomy.

Fear. Fear is a typical feeling associated with dying. Four specific fears associated with dying are fear of pain, fear of shortness of breath, fear of loneliness and abandonment, and fear of meaninglessness.

Fear of Pain. Many people assume that pain always accompanies death. Physiologically, there is no absolute indication that death is always painful. Psychologically, pain may occur based on the anxieties and separations related to dying. Terminally ill patients who do experience physical pain should have pain-relieving drugs available. Assure the patient and the family that

FIG. 10-8 Dying patients typically want someone whom they know and trust to stay with them. (iStockphoto/Thinkstock)

drugs will be given promptly when needed and that side effects of drugs can and will be managed. Patients can participate in their own pain relief by discussing pain relief measures and their effects. Most patients want their pain relieved without the side effects of grogginess or sleepiness. Pain relief measures do not need to deprive the patient of the ability to interact with others.[30]

Fear of Shortness of Breath. Respiratory distress and dyspnea are common near the end of life. The sensation of air hunger results in anxiety for the patient and family. Current therapies include opioids, bronchodilators, and oxygen, depending on the cause of the dyspnea. Anxiety-reducing agents (e.g., anxiolytics) may help produce relaxation.

Fear of Loneliness and Abandonment. Most terminally ill and dying people fear loneliness and do not want to be alone. Many dying patients are afraid that loved ones who are unable to cope with the patient's imminent death will abandon them. The simple presence of someone provides support and comfort (Fig. 10-8). Holding hands, touching, and listening are important nursing interventions. Providing companionship allows the dying person a sense of security.

Fear of Meaninglessness. Fear of meaninglessness leads people to review their lives. They review their intentions during life, examining actions and expressing regrets about what might have been. *Life review* helps patients recognize the value of their lives. Assist patients and their families in identifying the positive qualities of the patient's life. Practical ways of helping may include looking at photo albums or collections of important mementos. Sharing thoughts and feelings may enhance spirituality and provide comfort for the patient at this time. Respect and accept the practices and rituals associated with the patient's life review while remaining nonjudgmental.[30]

> *What we leave behind is not what is engraved in stone monuments, but what is woven into the lives of others.*
> *Pericles (fifth-century Greek statesman)*

Communication. Communication among health care providers, patient, and family is essential at the end of life. Empathy and active listening are essential components of communication in EOL care. *Empathy* is the identification with and understanding of another's situation, feelings, or motives. *Active listening* is paying attention to what is said, observing the patient's nonverbal cues, and not interrupting.

There may be silence. Frequently silence is related to the overwhelming feelings experienced at the end of life. Silence can also allow time to gather thoughts. Listening to the silence sends a message of acceptance and comfort. Communication also needs to consider the patient's ethnic, cultural, and religious backgrounds.

Patients and family members may have difficulties expressing themselves emotionally. Allow time for them to express their feelings and thoughts. Make time to listen and interact in a sensitive way to enhance the relationship among you, the patient, and the family. A family conference is one way to create a more conducive environment for communication.

Unusual communication by the patient may take place at the end of life. The patient's speech may become confused, disoriented, or garbled. Patients may speak to or about family members or others who have predeceased them, give instructions to those who will survive them, or speak of projects yet to be completed. Active, careful listening allows for the identification of specific patterns in the dying person's communication and decreases the risk for inappropriate labeling of behaviors.

PHYSICAL CARE. Nursing management related to physical care at the end of life focuses on symptom management and comfort rather than treatment for curing a disease or disorder (Table 10-8). The priority is meeting the patient's physiologic and safety needs. Physical care focuses on the needs for oxygen, nutrition, pain relief, mobility, elimination, and skin care. People who are dying deserve and require the same physical care as people who are expected to recover.

Postmortem Care. After the patient is pronounced dead, prepare or delegate preparation of the body for immediate viewing by the family with consideration for cultural customs and in accord with state law and agency policies and procedures. In some cultures and in some types of death, it may be important to allow the family to prepare or assist in preparing the body. In general, close the patient's eyes, replace dentures, wash the body as needed (placing pads under the perineum to absorb urine and feces), and remove tubes and dressings (if appropriate). The body is straightened, leaving the pillow to support the head and prevent pooling of blood and discoloration of the face. Allow the family privacy and as much time as they need with the deceased person. In the case of an unexpected or unanticipated death, preparation of the body for viewing or release to a funeral home depends on state law and agency policies and procedures.

SPECIAL NEEDS OF CAREGIVERS AND NURSES IN END-OF-LIFE CARE

Special Needs of Family Caregivers

Family caregivers are important in meeting the patient's physical and psychosocial needs. The role of caregivers includes working and communicating with the patient and other family members, supporting the patient's concerns, and helping the patient resolve any unfinished business. Families often face emotional, physical, and economic consequences as a result of caring for a family member who is dying. The caregiver's responsibilities do not end when the person is admitted to an acute care, inpatient hospice, or long-term care facility.

TABLE 10-8 NURSING MANAGEMENT

Physical Care at End of Life

Characteristic	Nursing Management
Pain	
• Pain may be a major symptom associated with terminal illness and the one most feared. • Pain can be acute or chronic. • Physical and emotional irritations can aggravate pain.	• Assess pain thoroughly and regularly to determine the quality, intensity, location, and contributing factors. • Minimize possible irritants such as skin irritations from wetness, heat or cold, and pressure. • Administer medications around the clock in a timely manner and on a regular basis to provide constant relief rather than waiting until the pain is unbearable and then trying to relieve it. • Provide complementary and alternative therapies such as guided imagery, massage, and relaxation techniques as needed (see Chapters 6 and 7). • Evaluate effectiveness of pain relief measures frequently to ensure that the patient is on a correct, adequate drug regimen. • Do not delay or deny pain relief measures to a terminally ill patient.
Delirium	
• A state characterized by confusion, disorientation, restlessness, clouding of consciousness, incoherence, fear, anxiety, excitement, and often hallucinations. • May be misidentified as depression, psychosis, anger, or anxiety. • Use of opioids or corticosteroids may cause delirium. • Underlying disease process may contribute to delirium. • Generally considered a reversible process.	• Perform a thorough assessment for reversible causes of delirium, including pain, constipation, and urinary retention. • Provide a room that is quiet, well lit, and familiar to reduce the effects of delirium. • Reorient the dying person to person, place, and time with each encounter. • Administer ordered benzodiazepines and sedatives as needed. • Stay physically close to frightened patient. Reassure in a calm, soft voice with touch and slow strokes of the skin. • Provide family with emotional support and encouragement in their efforts to cope with the behaviors associated with delirium. • Encourage the family to participate in care of the patient.
Restlessness	
• May occur as death approaches and cerebral metabolism slows.	• Assess for spiritual distress as a cause of restlessness and agitation. • Do not restrain. • Use soothing music; slow, soft touch and voice. • Limit the number of persons at the bedside.
Dysphagia	
• May occur because of extreme weakness and changes in level of consciousness.	• Identify the least invasive alternative routes of administration for drugs needed for symptom management. • Suction orally as needed.
Weakness and Fatigue	
• Expected at the end of life. • Metabolic demands related to disease process contribute to weakness and fatigue.	• Assess the patient's tolerance for activities. • Time nursing interventions to conserve energy. • Help the patient identify and complete valued or desired activities. • Provide support as needed to maintain positions in bed or chair. • Provide frequent rest periods.
Dehydration	
• May occur during the last days of life. • Hunger and thirst are rare in the last days of life. • As the end of life approaches, patients tend to take in less food and fluid.	• Assess mucous membranes frequently to prevent excessive dryness, which can lead to discomfort. • Maintain complete, regular oral care to provide for comfort and hydration of mucous membranes. • Do not force the patient to eat or drink. • Encourage consumption of ice chips and sips of fluids or use moist cloths to provide moisture to the mouth. • Use moist cloths and swabs for unconscious patients to avoid aspiration. • Apply lubricant to the lips and oral mucous membranes as needed. • Reassure family that cessation of food and fluid intake is a natural part of the process of dying.
Dyspnea	
• Subjective symptom. • Accompanied by fear of suffocation and anxiety. • Underlying disease process can exacerbate dyspnea. • Coughing and expectorating secretions become difficult.	• Assess respiratory status regularly. • Elevate the head and/or position patient on side to improve chest expansion. • Use a fan or air conditioner to facilitate movement of cool air. • Administer supplemental oxygen as ordered. • Suction PRN to remove accumulation of mucus from the airways. Suction cautiously in the terminal phase.

TABLE 10-8 NURSING MANAGEMENT—cont'd

Physical Care at End of Life

Characteristic	Nursing Management
Myoclonus	
• Mild to severe jerking or twitching sometimes associated with use of high dose of opioids. • Patient may complain of involuntary twitching of extremities.	• Assess for initial onset, duration, and any discomfort or distress experienced by patient. • If myoclonus is distressing or becoming more severe, discuss possible drug therapy modifications with the health care provider. • Changes in opioid medication may alleviate or decrease myoclonus.
Skin Breakdown	
• Skin integrity is difficult to maintain at the end of life. • Immobility, urinary and bowel incontinence, dry skin, nutritional deficits, anemia, friction, and shearing forces lead to a high risk for skin breakdown. • Disease and other processes may impair skin integrity. • As death approaches, circulation to the extremities decreases and they become cool, mottled, and cyanotic.	• Assess the skin for signs of breakdown. • Implement protocols to prevent skin breakdown by controlling drainage and odor and keeping the skin and any wound areas clean. • Perform wound assessments as needed. • Follow appropriate nursing management protocol for dressing wounds. • Follow appropriate nursing management protocol for a patient who is immobile, but consider realistic outcomes of skin integrity vs. maintenance of comfort. • Follow appropriate nursing management to prevent skin irritations and breakdown from urinary and bowel incontinence. • Use blankets to cover for warmth; never apply heat. • Prevent the effects of shearing forces.
Bowel Patterns	
• Constipation can be caused by immobility, use of opioid medications, lack of fiber in the diet, and dehydration. • Diarrhea may occur as muscles relax or from a fecal impaction related to the use of opioids and immobility.	• Assess bowel function. • Assess for and remove fecal impactions. • Encourage movement and physical activities as tolerated. • Encourage fiber in the diet if appropriate. • Encourage fluids if appropriate. • Use suppositories, stool softeners, laxatives, or enemas if ordered.
Urinary Incontinence	
• May result from disease progression or changes in the level of consciousness. • As death becomes imminent, the perineal muscles relax.	• Assess urinary function. • Use absorbent pads for urinary incontinence. • Follow appropriate nursing protocol for the consideration and use of indwelling or external catheters. • Follow appropriate nursing management to prevent skin irritations and breakdown from urinary incontinence.
Anorexia, Nausea, and Vomiting	
• May be caused by complications of disease process. • Drugs contribute to nausea. • Constipation, impaction, and bowel obstruction can cause anorexia, nausea, and vomiting.	• Assess the patient for complaints of nausea or vomiting. • Assess possible contributing causes of nausea or vomiting. • Have family provide the patient's favorite foods. • Discuss modifications to the drug regimen with the health care provider. • Provide antiemetics before meals if ordered. • Offer and provide frequent meals with small portions of favorite foods. • Offer culturally appropriate foods. • Provide frequent mouth care, especially after vomiting.

An understanding of the grieving process as it affects both the patient and family is important. Being present during a family member's dying process can be highly stressful. Recognize signs and behaviors among family members who may be at risk for abnormal grief reactions, and be prepared to intervene if necessary. Warning signs may include dependency and negative feelings about the dying person, inability to express feelings, sleep disturbances, a history of depression, difficult reactions to previous losses, perceived lack of social or family support, low self-esteem, multiple previous bereavements, alcoholism, or substance abuse. Caregivers with concurrent life crises (e.g., divorce) will be especially at risk.

Family caregivers and other family members need encouragement to continue their usual activities as much as possible. They need to discuss their activities and maintain some control over their lives.

Inform caregivers about appropriate resources for support, including respite care. Resources such as community counseling and local support may assist some people in working through their grief. Encourage caregivers to build a support system of extended family, friends, faith community, and clergy. The caregivers should have people to call on at any time to express any feelings they are experiencing. (The stressors and special needs of family caregivers are discussed in Chapter 4 on pp. 51-52.)

Special Needs of Nurses

Many nurses who care for dying patients do so because they are passionate about providing high-quality EOL care. Caring for patients and their families at the end of life is challenging and rewarding, but also intense and emotionally charged. A bond or connection may develop between you and the patient or

family. Be aware of how grief personally affects you. When you provide care for terminally ill or dying patients, you are not immune to feelings of loss. It is common to feel helpless and powerless when dealing with death. Express feelings of sorrow, guilt, and frustration.

Interventions are available that may help ease your physical and emotional stress. Be aware of what you can and cannot control. Recognizing personal feelings allows openness in exchanging feelings with the patient and the family. Realizing that it is okay to cry with the patient or family during the end of life may be important for your well-being.

To meet your personal needs, focus on interventions that will help decrease your stress. Get involved in hobbies or other interests, schedule time for yourself, maintain a peer support system, and develop a support system beyond the workplace.[31] Hospice agencies can help you cope through professionally assisted groups, informal discussion sessions, and flexible time schedules.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. An 80-year-old female patient is receiving palliative care for heart failure. Primary purpose(s) of her receiving palliative care is (are) to *(select all that apply)*
   - **a.** improve her quality of life.
   - **b.** assess her coping ability with disease.
   - **c.** have time to teach patient and family about disease.
   - **d.** focus on reducing the severity of disease symptoms.
   - **e.** provide care that the family is unwilling or unable to give.
2. The primary purpose of hospice is to
   - **a.** allow patients to die at home.
   - **b.** provide better quality of care than the family can.
   - **c.** coordinate care for dying patients and their families.
   - **d.** provide comfort and support for dying patients and their families.
3. A 67-year-old woman was recently diagnosed with inoperable pancreatic cancer. Before the diagnosis she was very active in her neighborhood association. Her husband is concerned because his wife is staying at home and missing her usual community activities. Which common EOL psychologic manifestation is she most likely demonstrating?
   - **a.** Peacefulness
   - **b.** Decreased socialization
   - **c.** Decreased decision making
   - **d.** Anxiety about unfinished business
4. For the past 5 years Tom has repeatedly asked his mother to donate his deceased father's belongings to charity, but his mother has refused. She sits in the bedroom closet, crying and talking to her long-dead husband. What type of grief is Tom's mother experiencing?
   - **a.** Adaptive grief
   - **b.** Disruptive grief
   - **c.** Anticipatory grief
   - **d.** Prolonged grief disorder
5. The home health nurse visits a 40-year-old patient with metastatic breast cancer who is receiving palliative care. The patient is experiencing pain at a level of 7 (on a 10-point scale). In prioritizing activities for the visit, the nurse would do which first?
   - **a.** Auscultate for breath sounds.
   - **b.** Administer PRN pain medication.
   - **c.** Check pressure points for skin breakdown.
   - **d.** Ask family about patient's food and fluid intake.
6. While caring for his dying wife, the husband states that his wife is a devout Roman Catholic but he is a Baptist. Who is considered the most reliable source for spiritual preferences concerning EOL care for the dying wife?
   - **a.** A priest
   - **b.** Dying wife
   - **c.** Hospice staff
   - **d.** Husband of dying wife
7. The family attorney informed a patient's adult children and wife that the patient did not have an advance directive after he suffered a serious stroke. Who is responsible for making the decision about EOL measures when the patient cannot communicate his or her specific wishes?
   - **a.** Notary and attorney
   - **b.** Physician and family
   - **c.** Wife and adult children
   - **d.** Physician and nursing staff
8. The children caregivers of an elderly patient whose death is imminent have not left the bedside for the past 36 hours. In the nurse's assessment of the family, what findings indicate the potential for an abnormal grief reaction to occur *(select all that apply)*?
   - **a.** Family cannot express their feelings to one another.
   - **b.** Dying patient is becoming more restless and agitated.
   - **c.** A family member is going through a difficult divorce.
   - **d.** Family talks with and reassures the patient at frequent intervals.
   - **e.** Siblings who were estranged from each other have now reunited.
9. A nurse has been working full time with terminally ill patients for 3 years. He has been experiencing irritability and mixed emotions when expressing sadness since four of his patients died on the same day. To optimize the quality of his nursing care, he should examine his own
   - **a.** full-time work schedule.
   - **b.** past feelings toward death.
   - **c.** patterns for dealing with grief.
   - **d.** demands for involvement in patient care.

1. a, d, 2. d, 3. b, 4. d, 5. b, 6. b, 7. c, 8. a, c, 9. c.

LEARNING OUTCOMES

1. Apply the terms *addiction, addictive behavior, substance misuse, substance abuse, dependence, tolerance, withdrawal, craving,* and *abstinence* to clinical situations.
2. Relate the effects of substance abuse to its resulting major health complications.
3. Differentiate among the effects of the use of stimulants, depressants, and cannabis.
4. Explain your role in promoting the cessation of smoking and tobacco use.
5. Summarize the nursing management and collaborative care of patients who experience intoxication, overdose, or withdrawal from stimulants and depressants.
6. Describe the incidence and effects of substance abuse and dependence in the older adult.

KEY TERMS

addiction, Table 11-1, p. 155
addictive behavior, Table 11-1, p. 155
craving, Table 11-1, p. 155
dependence, Table 11-1, p. 154
Korsakoff's psychosis, p. 159
physical dependence, Table 11-1, p. 155
psychologic dependence, Table 11-1, p. 155
substance abuse, Table 11-1, p. 155
tolerance, Table 11-1, p. 155
Wernicke's encephalopathy, p. 159

Substance abuse and addiction are serious problems affecting the health care system and society today. Addiction to chemical substances usually includes dependence on psychoactive agents that result in pleasure or modify thinking and perception. These include substances that are legal for adult use such as alcohol and tobacco, and illicit drugs including marijuana/hashish, cocaine, heroin, hallucinogens, inhalants, and prescription medications used nonmedically. In 2010 an estimated 22.6 million Americans ages 12 or older, or 8.9% of the population, were using illicit drugs monthly.[1] Americans' abuse and misuse of prescription medications such as analgesics, sedative-hypnotics, tranquilizers, and amphetamines have increased and can create harmful effects that are more deadly than the abuse of illicit drugs.[2]

The *Diagnostic and Statistical Manual of Mental Disorders IV* states that **substance abuse** and **dependence** (defined in Table 11-1) are specific psychiatric diagnoses.[3] Abused substances are discussed in detail in psychiatric and pharmacologic books and resources. Long-term management of patients who abuse substances is most often provided in specialized treatment facilities that provide both drug and behavior therapies.

Individuals who abuse substances use the health care system more than those who do not.[4] Almost every drug of abuse harms some tissue or organ in addition to the brain. Some health problems are caused by the effects of specific drugs, such as liver damage related to alcohol use or chronic obstructive pulmonary disease (COPD) related to smoking. Other health problems result from behaviors associated with substance abuse, such as injecting drugs or neglecting nutrition and hygiene. Common health complications related to substance abuse are identified in Table 11-2.

This chapter focuses on the role of the medical-surgical nurse in identifying and managing the substance-abusing patient in acute care settings. All nurses care for patients dependent on substances, whether they are identified as dependent or not, simply because of the prevalence of substance abuse and its association with health problems.

Reviewed by Carol Capitano, RN, PhD(C), College of Nursing, University of New Mexico, Albuquerque, New Mexico.

TABLE 11-1 TERMINOLOGY OF SUBSTANCE ABUSE

Term	Definition
Abstinence	Avoidance of substance use.
Addiction	Compulsive, uncontrollable dependence on a substance, behavior, or practice to such a degree that cessation causes severe emotional, mental, or physiologic reactions.
Addictive behavior	Behavior associated with maintaining an addiction.
Craving	Subjective need for a substance, usually experienced after decreased use or abstinence. Cue-induced craving occurs in the presence of experiences previously associated with drug taking.
Dependence	Reliance on a substance to the degree that its absence will cause impairment in function.
• Physical	Altered physiologic state from prolonged substance use; regular use is necessary to prevent withdrawal.
• Psychologic	Compulsive need to experience pleasurable response from the substance.
Overdose	Ingestion of excessive dose of one drug or a combination of similarly acting drugs. Leads to toxic reactions, including respiratory and circulatory arrest.
Relapse	Return to substance use after a period of abstinence.
Substance	Drug, chemical, or biologic entity that is self-administered. The words *"drug," "substance,"* and *"chemical"* are often used interchangeably.
Substance abuse	Overindulgence in a substance that has a negative impact on an individual's psychologic, physiologic, and/or social functioning.
Substance misuse	Use of a drug for purposes other than those for which it is intended.
Tolerance	Decreased effect of a substance that results from repeated exposure. It is possible to develop cross-tolerance to other substances in the same category.
Withdrawal	Combination of physiologic and psychologic responses that occur when there is abrupt cessation or reduced intake of a substance on which an individual is dependent.

TABLE 11-2 COMMON HEALTH PROBLEMS RELATED TO SUBSTANCE ABUSE

Substance	Health Problems*
Nicotine and smoking	• Chronic obstructive pulmonary disease (COPD) • Cancers of lung, mouth, larynx, esophagus, stomach, pancreas, bladder, prostate, cervix • Coronary artery disease, peripheral artery disease • Peptic ulcer disease, GERD
Cocaine	• Nasal sores, septal necrosis or perforation • Chronic sinusitis • Cardiac dysrhythmias, myocardial ischemia and infarction • Stroke • Psychosis
Amphetamines	• Cardiac dysrhythmias, myocardial ischemia and infarction • Death of brain cells • Mood disturbances, violent behavior, psychoses
Caffeine	• Gastrointestinal irritation, peptic ulcer disease, GERD • Anxiety, insomnia
Alcohol	• See Table 11-7 on p. 160
Sedative-hypnotics	• Possible memory impairment • Respiratory depression • Risk for falls and fractures
Opioids	• Sexual dysfunction • Gastric ulcers • Glomerulonephritis
Cannabis	• Bronchitis, chronic sinusitis • Cardiac dysrhythmias, myocardial ischemia and palpitations • Memory impairment • Impaired immune function
Behaviors	**Health Problems**
Injecting drugs	• Blood clots, phlebitis, skin infections • Hepatitis B and C • HIV/AIDS • Other infections: endocarditis, tuberculosis, pneumonia, meningitis, tetanus, bone and joint infections, lung abscesses
Snorting drugs	• Nasal sores, septal necrosis or perforation • Chronic sinusitis
Risky sexual behavior	• HIV/AIDS • Hepatitis B and C • Other sexually transmitted infections
Personal neglect	• Malnutrition, impaired immunity • Accidental injuries

*The health problems related to substance abuse are discussed in the appropriate chapters throughout the text where they are identified as risk factors for these problems.
GERD, Gastroesophageal reflux disease.

COMMON DRUGS OF ABUSE

NICOTINE

The addictive behavior that you are most likely to encounter is tobacco use. Nicotine is a stimulant substance in tobacco and is the most rapidly addictive of commonly abused drugs. Cigarette smoking is the predominant form of tobacco abuse in the United States. Tobacco use is the leading cause of preventable illness and death in the United States, claiming 443,000 lives a year.[5]

Effects of Use and Complications

The effects of nicotine are identical to those of other highly addictive stimulant drugs, including cocaine. Although users report that nicotine causes a depressant effect with relaxation and relief of anxiety, these effects are thought to occur when withdrawal is relieved with more nicotine.

Smoking is the most harmful method of nicotine use and can injure nearly every organ in the body. Smoking causes chronic lung disease, cardiovascular disease, and many cancers, and it is associated with cataracts, pneumonia, periodontitis, and abdominal aortic aneurysm[6] (see Table 11-2). The chronic respiratory irritation caused by exposure to cigarette smoke is

a key risk factor in the development of COPD and lung cancer (carcinogens in tobacco are also involved). The toxic gases inhaled in cigarette smoke constrict the bronchi, paralyze the cilia, thicken the mucus-secreting membranes, dilate the distal airways, and destroy the alveolar walls.

Carbon monoxide is a component of cigarette smoke. Its effects, combined with those of nicotine, increase the risk for coronary artery disease. Carbon monoxide has a high affinity for hemoglobin and combines with it more readily than oxygen, reducing the oxygen-carrying capacity of the blood. Smokers inhale less oxygen when smoking, further decreasing the available oxygen. Together with the increased myocardial oxygen consumption that nicotine causes, carbon monoxide significantly decreases the oxygen available to the myocardium. The result is a cycle of increases in heart rate and myocardial oxygen consumption that can lead to myocardial ischemia.

Children whose parents smoke have a higher rate of respiratory illnesses and sudden infant death syndrome. In adults, secondhand smoking is associated with decreased pulmonary function, increased risk for lung cancer, and increased mortality rates from coronary artery disease.

Women appear to be at greater risk than men for smoking-related diseases. Smoking in women is associated with increased menstrual bleeding and dysmenorrhea, early menopause, and infertility. Lung cancer related to smoking has surpassed breast cancer as the leading cause of cancer deaths among women.[7]

Although those who use smokeless tobacco (snuff, plug, and leaf) have less risk of lung disease than smokers, the use of smokeless tobacco is not without complications. Holding tobacco in the mouth increases the risk of cancer of the mouth, the cheek, the tongue, and gingiva nearly 50-fold. Smokeless tobacco users also experience the systemic effects of nicotine on the cardiovascular system, thus increasing the risk for cardiovascular disease.[6]

All users of nicotine in any form may develop complications directly related to the effects of nicotine itself, including an increased risk for peripheral artery disease, delayed wound healing, peptic ulcer disease, and gastroesophageal reflux disease (GERD).[6]

NURSING AND COLLABORATIVE CARE
TOBACCO USE

TOBACCO CESSATION

As a nurse, you have a professional responsibility to help individuals stop smoking or using tobacco. The Joint Commission mandates that every health professional is responsible for identifying tobacco users and providing them with information on ways to stop the use of tobacco. Hospitalization offers an ideal opportunity to provide cessation assistance because hospitals are tobacco-free environments, and patients may be more motivated to quit because of their illness. Patients who receive even brief advice and intervention from you are more likely to quit than those who receive no intervention.

Because many health care facilities are tobacco-free environments, an admitted patient who is addicted to nicotine may experience withdrawal symptoms since they are unable to smoke. These symptoms are the same as for the person who stops using tobacco "cold turkey." Ask each patient about his or her tobacco status. Unless contraindicated, offer nicotine replacement therapy to those who desire it to control with-

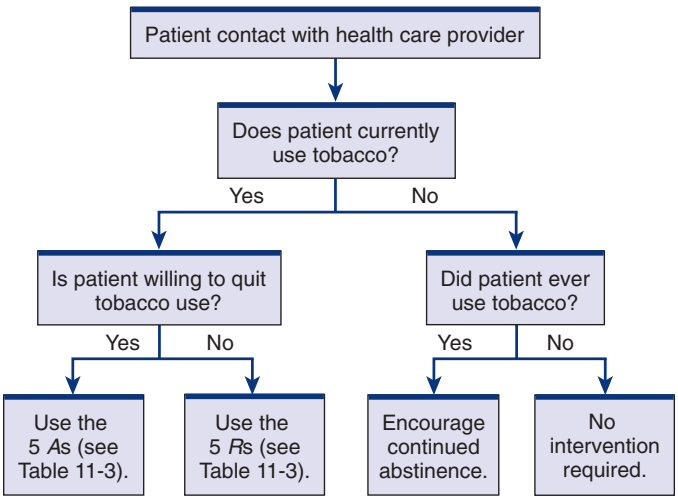

FIG. 11-1 Clinical practice guidelines: treating tobacco use and dependence.

TABLE 11-3 CLINICAL PRACTICE GUIDELINE

Treating Tobacco Use and Dependence

The Five *As* for Individuals Who Desire to Quit	The Five *Rs* for Individuals Unwilling to Quit
1. **Ask:** Identify all tobacco users at every contact.	1. **Relevance:** Ask the patient to indicate why quitting is personally relevant (e.g., family, health).
2. **Advise:** Strongly urge all tobacco users to quit.	2. **Risks:** Ask the patient to identify negative consequences of tobacco use (e.g., cough, shortness of breath).
3. **Assess:** Determine willingness to make a quit attempt.	3. **Rewards:** Ask the patient to identify potential benefits of stopping tobacco use (e.g., saving money, feeling better).
4. **Assist:** Aid the patient in developing a plan to quit.	4. **Roadblocks:** Ask patient to identify barriers or impediments to quitting (e.g., weight gain, partner smokes).
5. **Arrange:** Schedule follow-up contact.	5. **Repetition:** Repeat process every clinic visit.

TABLE 11-4 INPATIENT TOBACCO CESSATION INTERVENTIONS

Take the following steps for every hospitalized patient.

- Ask each patient on admission if he or she uses tobacco and document tobacco use status.
- For current tobacco users, list tobacco use status on the admission problem list and as a discharge diagnosis.
- Use counseling and medication to help all tobacco users maintain abstinence and to treat withdrawal symptoms.
- Provide advice and assistance on how to quit during hospitalization and remain abstinent after discharge.
- Arrange for follow-up regarding smoking status. Supportive contact should be provided for at least a month after discharge.

Source: Agency for Healthcare Research and Quality: *AHCPR supported clinical practice guideline: treating tobacco use and dependence: 2008 update,* Washington, DC, 2008, US Public Health Service.

drawal symptoms during their hospitalization. These symptoms include craving, restlessness, depression, headache, hyperirritability, drowsiness or insomnia, decreased BP and heart rate, and increased appetite.

With each patient encounter, encourage the patient to quit and offer specific smoking cessation interventions. The Agency for Healthcare Research and Quality has issued clinical practice guidelines for clinicians, including nurses, to use to motivate users to quit[8] (Tables 11-3 and 11-4 and Fig. 11-1). Use these brief clinical interventions, called the "five *A*s," with each patient encounter. These interventions are designed to identify tobacco users, encourage them to quit, determine their willingness to quit, assist them in quitting, and arrange for follow-up to prevent relapse.

If a tobacco user is unwilling to quit, *motivational interventions* based on the principles of motivational interviewing have been shown to increase future quit attempts. The content areas that should be addressed in a motivational counseling intervention can be captured by the "five *R*s": relevance, risks, rewards, roadblocks, and repetition. A patient teaching guide (Table 11-5) expands on the fourth "A" strategy, "Assist: aid the patient in quitting."

The patient is most likely to achieve long-term tobacco cessation with a combination of nicotine replacement products,

TABLE 11-5 PATIENT TEACHING GUIDE

Smoking and Tobacco Use Cessation

The following interventions are methods that work for quitting tobacco use. Tobacco users have the best chance of quitting if they use more than one method.

Develop a Quit Plan

- Set a quit date, ideally within 2 weeks.
- Talk to your health care provider about getting help to quit.
- Tell family, friends, and co-workers about quitting and request understanding and support.
- Anticipate withdrawal symptoms and challenges when quitting.
- Before quitting, avoid smoking in places where you spend a lot of time (work, car, home).
- Throw away all tobacco products from your home, car, and work.
- Do not take even a single puff or dip after the quit date. Total abstinence is essential.

Use Approved Nicotine Replacement Systems

- Use a nicotine replacement agent unless you are a pregnant or nursing woman (see Table 11-6).
- Do not use other forms of tobacco when using nicotine replacement systems.

Dealing With Urges to Use Tobacco

- Identify situations that may cause you to want to smoke or use other tobacco, such as being around other smokers, being under time pressure, getting into an argument, feeling sad or frustrated, and drinking alcohol.
- Avoid difficult situations while you are trying to quit. Try to lower your stress level.
- Exercise can help, such as walking, jogging, or bicycling.
- Distract yourself from thoughts of smoking and the urge to use tobacco by talking to someone, getting busy with a task, or reading a book.
- Drink a lot of water.
- Take a shower or soak in the tub.

Support and Encouragement

- If you have tried to stop using tobacco before, identify what helped and what hurt in previous quit attempts.
- Joining a quit-tobacco support group will increase your chances of stopping permanently.
- If you get the urge for tobacco, call someone to help talk you out of it—preferably an ex-user.
- Do not be afraid to talk about how you feel while quitting, especially fears of not being able to quit for good. Ask your spouse or partner, friends, and co-workers to support you. Self-help materials and hot lines are also available:
  - American Lung Association: 800-586-4872; *www.lungusa.org*
  - American Cancer Society: 800-227-2345; *www.cancer.org*
  - National Cancer Institute: 877-448-7848 or 800-784-8669; *www.smokefree.gov*
  - Make Smoking History, Massachusetts Department of Public Health: 800-784-8669; *http://makesmokinghistory.org*

Avoiding Relapse

Most relapses occur within the first 3 months after quitting. Do not be discouraged if you start using tobacco again. Remember, most people try several times before they finally quit. Explore different ways to break habits. You may have to deal with some of the following triggers that cause relapse.

- *Change your environment.* Get rid of cigarettes, tobacco (in any form), and ashtrays in your home, car, and place of work. Get rid of the smell of cigarettes in your car and home.
- *Alcohol.* Consider limiting or stopping alcohol use while you are quitting tobacco.
- *Other smokers at home.* Encourage housemates to quit with you. Work out a plan to cope with others who smoke, and avoid being around them.
- *Weight gain.* Tackle one problem at a time. Work on quitting tobacco first. You will not necessarily gain weight, and increased appetite is often temporary.
- *Negative mood or depression.* If these symptoms persist, talk to your health care provider. You may need treatment for depression.
- *Withdrawal symptoms.* Your body will go through many changes when you quit tobacco. You may have a dry mouth, cough, or scratchy throat, and you may feel irritable. The nicotine patch or gum may help with cravings (see Table 11-6).
- *Thoughts.* Get your mind off tobacco. Exercise and do things you enjoy.
- *Keep a list.* Keep a list of "slips" and near-slips, what caused them, and what you can learn from them.
- *Focus on the benefits of quitting:*
  1. At 20 minutes after you quit, blood pressure decreases, pulse rate drops, and the body temperature of your hands and feet increases.
  2. At 12 hours, the carbon monoxide level in your blood drops to normal, and the oxygen level in your blood increases to normal.
  3. At 24 hours, your chance of a heart attack decreases.
  4. At 48 hours, nerve endings start regrowing, and the ability to smell and taste is enhanced.
  5. At 2 weeks to 3 months, your circulation improves; walking becomes easier; lung function increases; and coughing, sinus congestion, fatigue, and shortness of breath decrease.
  6. At 1 year, your risk of heart disease decreases to half that of a smoker.
  7. By 10 to 15 years, your risk of stroke, lung and other cancers, and early death returns to nearly the level of people who have never smoked.

TABLE 11-6 DRUG THERAPY

Smoking Cessation*

Agents	Common Side Effects	Considerations
Nicotine Replacement Agents		
Nicotine Gum (OTC) Nicorette 2 mg, 4 mg • Use 12 wk or more • Use 9-12 pieces/day • Maximum dose: 30 pieces of 2 mg, 20 pieces of 4 mg	Hiccups, mouth ulcers, indigestion, jaw pain	Specific 30-min chewing regimen with periods of holding the gum between cheek and teeth. Avoid food and drink 15 min before and during use.
Nicotine Lozenge (OTC) Commit 2 mg, 4 mg • Use 8-12 wk or more • Use 1 lozenge q1-2hr tapering to 1 lozenge q4-8hr in 12 wk	Nausea and indigestion, hiccups, headache, cough, mouth soreness, flatulence	Dissolves in the mouth in 20-30 min. Chewing and swallowing the lozenge increases GI side effects. Avoid food and drink during use.
Nicotine Patch (OTC) NicoDerm CQ, Habitrol, Nicotine transdermal system • 18- or 24-hr doses • Use ≥8 wk	Transient itching, burning, and redness at patch site. Sleep disturbances with 24-hr patch	Provides steady level of nicotine and is easy to use. Cannot be used by those with adhesive allergies.
Nicotine Nasal Spray Nicotrol NS • Use up to 6 mo	Nose and throat irritation, sneezing, rhinitis, watery eyes, cough	Requires a prescription. Provides fastest nicotine delivery and highest nicotine levels. Most irritating product.
Nicotine Inhaler Nicotrol nicotine inhalation system • Delivers 4 mg • Use up to 6 mo	Cough. Nose, mouth, and throat irritation. Heartburn and nausea	Requires a prescription. Simulates smoking with mouthpiece and nicotine cartridge. May not be advisable for those with asthma or pulmonary disease.
Non-Nicotine Agents		
Bupropion (Zyban) • 150 mg/day for 3 days, then 150 mg bid • Use 12 wk; can use up to 6 mo or longer	Insomnia, dry mouth, irritability, anorexia	Contraindicated with history of seizures or eating disorders. Promotes weight loss. First choice for smokers with depression.
Varenicline (Chantix)† • 0.5 mg/day for 3 days, 0.5 mg bid for 4 days, then 1 mg bid • Use 12 wk; additional 12 wk recommended for those who stop smoking to increase chance of long-term abstinence	Nausea, sleep disturbances, constipation, flatulence, vomiting, headache	If taken concurrently with nicotine replacement therapy, incidence of nausea, headache, vomiting, dizziness, dyspepsia, and fatigue is increased, but nicotine pharmacokinetics not affected.
Nortriptyline (Aventyl)‡ • 25-75 mg/day • Use 12 wk, longer if depressed	Dry mouth, drowsiness, dizziness	Must have stable ECG. Do not use immediately after MI.
Clonidine (Catapres)‡ • 0.1 mg q6hr PRN for craving	Dry mouth, drowsiness, constipation, hypotension	Used to control craving. Change position slowly to prevent postural hypotension.

*OTC nicotine replacement agents are also available in generic forms. Additional information and patient instructions are available from the American Lung Association at *www.lungusa.org*.
†See the Drug Alert for varenicline on p. 157.
‡Nortriptyline and clonidine are not approved by the U.S. Food and Drug Administration for treatment of smoking cessation but have been used successfully for this purpose.

medications, behavioral approaches, and support.[9] Support the patient by providing the resources needed to continue or start a quit attempt.

A variety of nicotine replacement products can be used to reduce the craving and withdrawal symptoms associated with tobacco cessation (Table 11-6). These agents enable a smoker to reduce nicotine previously obtained from cigarettes with a system that delivers the drug more slowly and eliminates the carcinogens and gases associated with tobacco smoke. Nicotine replacement therapy is generally not recommended for pregnant women and people who have experienced an acute myocardial infarction within 2 weeks, have unstable angina, or have life-threatening dysrhythmias.

Varenicline (Chantix) is a drug used to aid smoking cessation. Varenicline is unique in that it has both agonist and antagonist actions at nicotinic receptors. Its agonist activity at one subtype of nicotinic receptors provides some nicotine effects to ease the withdrawal symptoms. It also prevents stimulation of the dopamine system by blocking another subtype of nicotinic receptors. Thus it eases withdrawal symptoms while blocking the effects of nicotine if a person resumes smoking.

Non-nicotine drugs may also be used in smoking cessation. Bupropion (Zyban) is an antidepressant approved as an aid to quit smoking. It reduces the urge to smoke, reduces some symptoms of withdrawal, and helps prevent weight gain associated with smoking cessation. Nortriptyline (Aventyl) and clonidine (Catapres) are not approved by the U.S. Food and Drug Administration (FDA) for use in smoking cessation, but are used in some cases to reduce withdrawal symptoms and promote cessation.[10]

DRUG ALERT: Varenicline (Chantix) and Bupropion (Zyban)
- Serious neuropsychiatric symptoms such as changes in behavior, hostility, agitation, depressed mood, suicidal thoughts and behavior, and attempted suicide can occur.
- Advise patients to stop taking these drugs and contact a health care provider immediately if they experience any of these symptoms.

Participation in tobacco cessation programs is recommended in conjunction with nicotine replacement therapy. You should be aware of community resources that assist individuals who are motivated to quit. Local chapters of the American Lung Association and the American Cancer Society have information on available programs. Cessation programs may involve hypnosis, acupuncture, behavioral interventions, aversion therapy, group support programs, individual therapy, and self-help options. Behavioral approaches teach patients to avoid high-risk situations for smoking relapse, such as those that promote *cue-induced craving.* Cessation programs also promote development of other coping skills, such as cigarette refusal skills, assertiveness, alternative activities to cope with stress, and use of peer support systems.

Women are less successful than men in quitting smoking. Some of the reasons include concern about weight gain, less responsiveness to nicotine replacement therapy, influences of the menstrual cycle, and inadequate emotional support from others. Smoking-associated environmental cues may be more influential in smoking behavior in women than in men. The identification of gender differences in smoking cessation suggests that women who use nicotine replacement do better with nicotine inhalers than the nicotine patch and that women can increase their chances for quitting by timing their attempt to coincide with the first half of their menstrual cycles.[7]

ALCOHOL

Almost half of Americans ages 12 and older consume alcohol (Fig. 11-2). Although most people use alcohol in moderation, it is estimated that alcoholism, or alcohol dependence, affects 7% of the population.[1] Alcoholism is currently viewed as a chronic, progressive, potentially fatal disease if untreated. Alcohol dependence generally occurs over a period of years and may be preceded by heavy social drinking.

Effects of Use and Complications

Alcohol affects almost all cells of the body and has complex effects on the neurons in the central nervous system (CNS). Alcohol, like other addictive substances, causes increased levels of dopamine in the brain, but it also depresses all areas and functions of the CNS.[11] Alcohol is absorbed directly from the stomach and small intestine. In a moderate drinker the metabolism of alcohol by the liver and the stomach occurs at a relatively constant rate of approximately one drink (7 g of alcohol) per hour. One drink is equal to 12 oz of beer, 5 oz of wine, or 1 oz of distilled spirits. Because women have significantly lower rates of stomach metabolism, they have higher blood alcohol levels than men do after the same amount of alcohol intake.[12]

FIG. 11-2 Alcohol is often used to cope with the stresses of life. (Digital Vision/Thinkstock)

The effects of alcohol are related to the concentration of alcohol and individual susceptibility to the drug. The concentration of alcohol in the body can be determined by assessing the blood alcohol concentration (BAC). For the person who is not dependent on alcohol, the BAC is generally predictable of alcohol's effects. The relationship between BAC and behavior is different in a person who has developed tolerance to alcohol and its effects. This tolerant individual is usually able to drink large amounts without obvious impairment and perform complex tasks without problems at BAC levels several times higher than levels that would produce obvious impairment in the nontolerant drinker.[12] In the United States the legal limit for intoxication is 0.08 mg% BAC as measured by a breath device, urinalysis, or blood test.

Individuals who abuse alcohol have many health problems (Table 11-7), which frequently are the reasons they seek health care. One serious complication of chronic alcohol abuse is **Wernicke's encephalopathy,** an inflammatory, hemorrhagic, degenerative condition of the brain. Wernicke's encephalopathy is caused by a thiamine deficiency resulting from poor diet and alcohol-induced suppression of thiamine absorption. This syndrome is readily reversible with administration of thiamine. Untreated or progressive Wernicke's encephalopathy may lead to **Korsakoff's psychosis,** an irreversible form of amnesia characterized by loss of short-term memory and an inability to learn.

Complications may also arise from the interaction of alcohol with commonly prescribed or over-the-counter (OTC) drugs. Drugs that interact with alcohol in an additive manner include antihypertensives, antihistamines, and antianginals. Alcohol taken with aspirin may cause or exacerbate GI bleeding. Alcohol taken with acetaminophen may increase the risk of liver damage. Potentiation and cross-tolerance with other CNS depressants also may occur. *Potentiation* occurs when an additional CNS depressant is taken with alcohol, increasing the effect. *Cross-tolerance,* requiring an increased dose for effect, occurs when an alcohol-dependent individual is alcohol free and receives other CNS depressants.

NURSING AND COLLABORATIVE CARE
ALCOHOL DEPENDENCE

ALCOHOL INTOXICATION

Acute alcohol toxicity may occur with binge drinking or the use of alcohol with other CNS depressants. It manifests as an emergency primarily because of the narrow range between the intoxicating, the anesthetic, and the lethal doses of alcohol. Alcohol-induced CNS depression leads to respiratory and circulatory failure.

Obtain as accurate a history as possible and assess for injuries, trauma, diseases, and hypoglycemia. No antidote for alcohol is available. Implement supportive care measures to maintain airway, breathing, and circulation (the ABCs) until detoxification is complete and the alcohol is metabolized. Fre-

TABLE 11-7 EFFECTS OF CHRONIC ALCOHOL ABUSE

Body System	Effects
Central nervous system	Alcoholic dementia. Wernicke's syndrome (confusion, nystagmus, paralysis of ocular muscles, ataxia). Korsakoff's psychosis (confabulation, amnesic disorder). Impairment of cognitive function, psychomotor skills, abstract thinking, and memory. Depression, attention deficit, labile moods, seizures, sleep disturbances.
Peripheral nervous system	Peripheral neuropathy, including pain, paresthesias, weakness.
Immune system	Increased risk for tuberculosis and viral infections. Increased risk for cancer of oral cavity, pharynx, esophagus, liver, colon, rectum, and possibly breast.
Hematologic system	Bone marrow depression, anemia, leukopenia, thrombocytopenia, blood clotting abnormalities.
Musculoskeletal system	Painful, tender swelling of large muscle groups. Painless progressive muscle weakness and wasting; osteoporosis.
Cardiovascular system	Elevated pulse and blood pressure. Decreased exercise tolerance. Cardiomyopathy (irreversible). Increased risk for hemorrhagic stroke, coronary artery disease, hypertension, sudden cardiac death.
Hepatic system	Steatosis* (nausea, vomiting, hepatomegaly). Alcoholic hepatitis* (anorexia, nausea, vomiting, fever, chills, abdominal pain). Cirrhosis, hepatocellular cancer.
Gastrointestinal system	Gastritis, gastroesophageal reflux disease (GERD), peptic ulcer, esophagitis, esophageal varices, enteritis, colitis, Mallory-Weiss tear, chronic pancreatitis.
Nutrition	Decreased appetite, indigestion, malabsorption, vitamin deficiencies (especially thiamine).
Urinary system	Diuretic effect from inhibition of antidiuretic hormone.
Endocrine and reproductive systems	Altered gonadal function, testicular atrophy, decreased beard growth, decreased libido, diminished sperm count, gynecomastia, glucose intolerance.
Integumentary system	Palmar erythema, spider angiomas, rosacea, rhinophyma.

*In the early stages of the disease this is reversible if the person quits drinking.

TABLE 11-8 CLINICAL MANIFESTATIONS AND TREATMENT OF ALCOHOL WITHDRAWAL

Clinical Manifestations	Drug Treatment
Minor Withdrawal Syndrome	
Tremulousness, anxiety ↑ Heart rate ↑ Blood pressure Sweating Nausea Hyperreflexia Insomnia ↑ Hyperactivity without seizures	Benzodiazepines (such as chlordiazepoxide [Librium], lorazepam [Ativan], or diazepam [Valium]) to stabilize vital signs, reduce anxiety, and prevent seizures and delirium Thiamine (prevents Wernicke's encephalopathy) Multivitamins (folic acid, B vitamins) Magnesium sulfate (if serum magnesium is low) IV glucose solution
Major Withdrawal Syndrome	
Visual or auditory hallucinations Gross tremors Seizures Alcohol withdrawal delirium	Continued use of benzodiazepines Carbamazepine (Tegretol) or phenytoin (Dilantin) to treat seizures Antipsychotic agents (e.g., chlorpromazine [Thorazine], haloperidol [Haldol]) if psychosis persists after benzodiazepine administration

quently monitor vital signs and level of consciousness. Treat alcohol-induced hypotension with IV fluids. Do not give stimulants to an intoxicated patient. In addition, do not give other depressants because of their additive effects.

Patients experiencing hypoglycemia are given glucose-containing IV solutions. Glucose administration may precipitate Wernicke's encephalopathy in a previously unaffected patient. To identify Wernicke's encephalopathy in the patient with chronic alcoholism, assess the patient for eye abnormalities (e.g., nystagmus, paralysis of the lateral rectus muscles), ataxia, and confusion.

Because the intoxicated patient may have symptoms similar to those of encephalopathy and because untreated encephalopathy may progress to Korsakoff's psychosis, administer IV thiamine before or with IV glucose solutions to all intoxicated patients. Many patients also have decreased serum magnesium levels and other signs of malnutrition, so health care providers frequently add multivitamins and magnesium to the IV fluids.

Agitation and anxiety are common. Stay with the patient as much as possible, orienting to reality as necessary. Assess the patient for increasing belligerence and a potential for violence. Because the patient is also at risk for injury because of lack of coordination and impaired judgment, use protective measures. It is critical to continue assessment and interventions until the BAC has fallen to at least 100 mg/dL (0.10 mg%) and until any associated disorders or injuries have been ruled out.

ALCOHOL WITHDRAWAL SYNDROME

A patient with alcohol dependence who is hospitalized for any condition can develop *alcohol withdrawal syndrome* when the ingestion of alcohol is abruptly stopped. The onset of signs and symptoms of alcohol withdrawal is variable depending on the patient's drinking pattern. Initial symptoms may occur 4 to 6 hours after the last drink, and symptoms may last up to 14 days. Table 11-8 presents the clinical manifestations and suggested drug treatment for alcohol withdrawal. Since the symptoms of alcohol withdrawal do not always progress in a predictable manner, use a clinical withdrawal assessment tool, such as the Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised (CIWA-Ar), to determine treatment (see Table 11-9 on p. 162 and eTable 11-1 on the website for this chapter).

Alcohol withdrawal delirium is a serious complication that can occur from 30 to 120 hours after the last drink. The greater the patient's dependence on alcohol, the greater the risk of serious withdrawal symptoms. Delirium components include disorientation, visual or auditory hallucinations, and increased hyperactivity without seizures. Death may result from hyperthermia, peripheral vascular collapse, or cardiac failure.[13]

Anticipating withdrawal syndrome in patients is important because alcohol withdrawal delirium can usually be prevented or controlled by administration of benzodiazepines such as

NURSING CARE PLAN 11-1

Patient in Alcohol Withdrawal

NURSING DIAGNOSIS **Acute confusion** *related to* alcohol abuse and delirium *as evidenced by* increased agitation, hallucinations, fluctuations in level of consciousness and psychomotor activity, disorientation, or misperceptions.

PATIENT GOALS
1. Demonstrates decrease in alcohol withdrawal severity.
2. Experiences no injury or complications of acute alcohol withdrawal.
3. Experiences no hallucinations.
4. Experiences no seizures.

Outcomes (NOC)

Substance Withdrawal Severity

- Substance cravings ___
- Agitation ___
- Hyperreflexia ___
- Tremors ___
- Change in vital signs ___
- Disorientation ___
- Altered level of consciousness ___
- Difficulty interpreting environmental stimuli ___
- Misinterpretation of cues ___
- Sleeplessness ___
- Hallucinations ___
- Seizures ___

Measurement Scale
1 = Severe
2 = Substantial
3 = Moderate
4 = Mild
5 = None

Distorted Thought Self-Control

- Asks for validation of reality ___
- Reports decrease in hallucinations or delusions ___
- Perceives environment accurately ___
- Exhibits logical thought flow patterns ___
- Exhibits reality-based thinking ___
- Exhibits appropriate thought content ___

Measurement Scale
1 = Never demonstrated
2 = Rarely demonstrated
3 = Sometimes demonstrated
4 = Often demonstrated
5 = Consistently demonstrated

Interventions (NIC) and *Rationales*

Substance Use Treatment: Alcohol Withdrawal

- Monitor vital signs during withdrawal *to identify extreme autonomic nervous system response.*
- Administer antiseizure drugs or sedatives *to prevent alcohol withdrawal delirium and relieve other symptoms during withdrawal.*
- Administer vitamin therapy *to prevent Wernicke's syndrome.*
- Address hallucinations in a therapeutic manner *to provide reality orientation.*
- Determine CIWA-Ar score every 4 hours until it is less than 8 for 24 hours *to assess need for medications.*
- Provide emotional support to patient/family *to decrease anxiety.*

Seizure Precautions

- Keep suction, Ambu-bag, and oral or nasopharyngeal airway at bedside *to establish respiratory function after seizure activity.*
- Use padded side rails and keep side rails up *to prevent injury during seizure activity.*

Delirium Management

- Monitor neurologic status on an ongoing basis *to determine appropriate interventions.*
- Verbally acknowledge the patient's fears and feelings to *decrease anxiety.*
- Provide patient with information about what is happening and what can be expected to occur in the future *to assist in reality orientation.*
- Maintain a well-lit environment that reduces sharp contrasts and shadows *to reduce external stimuli.*
- Remove stimuli, when possible, that create misperception in a particular patient (e.g., pictures on the wall or television) *to reduce misinterpretation of environment.*
- Inform patient of person, place, and time *to promote orientation.*
- Use environmental cues (e.g., signs, pictures, clocks, calendars, and color coding of environment) *to stimulate memory, reorient, and promote appropriate behavior.*

NURSING DIAGNOSIS **Ineffective self-health management** *related to* inadequate coping mechanisms and resources *as evidenced by* abuse of alcohol

PATIENT GOALS
1. Acknowledges a substance abuse problem
2. Commits to alcohol cessation
3. Identifies positive coping mechanisms and resources to use during alcohol abstinence

Outcomes (NOC)

Alcohol Abuse Cessation Behavior

- Expresses willingness to stop alcohol use ___
- Develops effective strategies to eliminate alcohol use ___
- Commits to alcohol elimination strategies ___
- Uses strategies to cope with withdrawal symptoms ___
- Uses effective coping mechanisms ___
- Adjusts lifestyle to promote alcohol elimination ___
- Obtains assistance from health professional ___
- Uses available support groups ___
- Eliminates alcohol use ___

Measurement Scale
1 = Never demonstrated
2 = Rarely demonstrated
3 = Sometimes demonstrated
4 = Often demonstrated
5 = Consistently demonstrated

Interventions (NIC) and *Rationales*

Substance Use Treatment

- Encourage patient to take control over own behavior *to change undesired behaviors.*
- Discuss with patient the impact of substance use on medical condition or general health *to promote acknowledgment of consequences of use.*
- Identify constructive goals with patient *to provide alternatives to the use of substances to reduce stress.*
- Assist patient to learn alternative methods of coping with stress or emotional distress *to reduce substance use.*
- Identify support groups in the community for long-term substance abuse treatment *to promote continued abstinence.*

TABLE 11-9 CLINICAL INSTITUTE WITHDRAWAL ASSESSMENT OF ALCOHOL SCALE, REVISED (CIWA-Ar)*

The CIWA-Ar is a widely used tool for assessing alcohol withdrawal. The categories assessed are:

- Agitation
- Anxiety
- Auditory disturbances
- Headache, fullness in head
- Nausea and vomiting
- Orientation and clouding of sensorium
- Paroxysmal sweats
- Tactile disturbances
- Tremor
- Visual disturbances

Source: University of Maryland School of Medicine. Available at *http://umem.org/files/uploads/1104212257_CIWA-Ar.pdf*.

*evolve The complete CIWA-Ar and instructions for how to use it are presented in eTable 11-1 (available on the website for this chapter).

chlordiazepoxide (Librium) or lorazepam (Ativan).[13] A quiet, calm environment is important to prevent exacerbation of symptoms. Avoid the use of restraints and IV lines whenever possible. Supportive care is needed to ensure adequate rest and nutrition. The nursing care for a patient in alcohol withdrawal is presented in NCP 11-1 on p. 161.

OTHER DRUGS OF ABUSE

STIMULANTS

Frequently abused stimulants include cocaine and amphetamines. The use of cocaine is illegal, but amphetamines may be prescribed for the treatment of narcolepsy, attention deficit disorders, and weight control. All stimulants work in part by increasing the amount of dopamine in the brain, producing euphoria, alertness, and rapid dependence (see Table 11-10). Cocaine and amphetamines also stimulate the peripheral nervous and cardiovascular systems, thus creating adrenalin-like effects.[11]

Caffeine is the most widely used psychoactive substance in the world, but it is very weak when compared with the other stimulants. It is not regulated, and its use is safe in most people. Recently, more problems with caffeine have occurred because of high doses in popular "power" drinks. Caffeine dependence in a hospitalized patient can result in withdrawal headaches after general anesthesia or during restrictions on usual coffee or tea intake.

NURSING AND COLLABORATIVE CARE STIMULANT ABUSE

OVERDOSE

Almost 500,000 people are treated each year for cocaine and amphetamine use.[1] At high levels of overdose, the patient experiences restlessness, paranoia, agitated delirium, confusion, and repetitive stereotyped behaviors. Death is often related to stroke, dysrhythmias, or myocardial infarction.[14]

Emergency management of cocaine and amphetamine toxicity depends on the clinical manifestations at the time of treatment (Table 11-11). Therapy may be complicated by the possibility that the patient has combined the use of stimulants with heroin, alcohol, or phencyclidine hydrochloride (PCP). A specific antidote for cocaine and amphetamine toxicity is not available.

WITHDRAWAL

It is unusual for an individual dependent on stimulants to be hospitalized for management of withdrawal symptoms. However, you may identify withdrawal symptoms in a patient dependent on cocaine or amphetamines who is hospitalized for other health problems. Withdrawal from cocaine and amphetamines usually causes few physical symptoms, but fatigue, prolonged sleep, and depression occur in some individuals (see Table 11-10). Craving for the drug is intense during the first hours to days of drug cessation and may continue for weeks. Treatment is supportive.

DEPRESSANTS

Commonly abused depressants include sedative-hypnotics and opioids. With the exception of alcohol and some federally regulated drugs, most CNS depressants are medically useful. These drugs are widely recognized for their rapid development of tolerance and dependence and for medical emergencies involving overdose and withdrawal.

Sedative-Hypnotics

Commonly abused sedative-hypnotic agents include barbiturates, benzodiazepines, and barbiturate-like drugs. Barbiturates are preferred as recreational drugs because they more frequently produce euphoric effects. Sedative-hypnotic drugs depress the CNS, causing sedation at low doses and sleep at high doses. Excessive amounts produce an initial euphoria and an intoxication that resembles that of alcohol. The effects of sedative-hypnotics are presented in Table 11-10.

Tolerance develops rapidly to the effects of the drug, requiring higher doses to achieve euphoria. Tolerance may not develop to the brainstem-depressant effects. As a result, an increased dose may trigger hypotension and respiratory depression, resulting in death.[15]

Health problems resulting from the use of sedative-hypnotics are identified in Table 11-2. Complications associated with IV use of the drugs (e.g., blood-borne infections) also occur. An overdose of sedative-hypnotics can cause death from respiratory depression and arrest.

Opioids

Commonly abused opioids are identified in Table 11-10. Individuals dependent on opioids include those who use illegal drugs sold on the street and those who misuse prescription opioids. Heroin is a commonly used street drug. Misusing medications such as oxycodone (OxyContin) and acetaminophen plus hydrocodone (Vicodin) can result in the same harmful consequences as abusing heroin (Fig. 11-3). By acting on opiate receptors and neurotransmitter systems in the CNS, opioids cause CNS depression and have a major effect on the brain reward system. Cross-tolerance among the opioids is common. Cross-tolerance to other CNS depressants does not occur. However, additive effects of other CNS depressants may cause increased CNS depression.

Opioids are usually injected IV, increasing the user's risk for human immunodeficiency virus (HIV) infection, hepatitis B virus (HBV) infection, and hepatitis C virus (HCV) infection. In addition, drug abuse by any route increases the risk of contracting HIV because of risky sexual behaviors in exchange for drugs or money or because of lack of inhibition. Like all depressants, opioids can cause death from CNS and respiratory

TABLE 11-10 COMMONLY ABUSED ADDICTIVE SUBSTANCES

Substance	Physiologic and Psychologic Effects	Manifestations of Withdrawal	Treatment of Withdrawal
Stimulants			
Cocaine and Amphetamines			
Cocaine (street names: crack, snow, nose candy, coke, flake) dextroamphetamine (Dexedrine) methamphetamine (Desoxyn) methylphenidate (Ritalin) phentermine (Adipex-P)	*Early:* euphoria, grandiosity, excitation, restlessness, insomnia; tachycardia, hypertension, angina, dysrhythmias; dyspnea, tachypnea; sexual arousal, delayed orgasm; anorexia *Long-term:* depression, hallucinations, tremors, myocardial infarction, heart failure, cardiomyopathy; lung congestion; rhinorrhea; loss of interest in sexual activity	Severe craving, severely depressed mood, exhaustion, prolonged sleep, vivid dreams, apathy, irritability, disorientation	No specific drug therapy is effective in treating withdrawal. Supportive care includes taking measures to decrease agitation and restlessness in the early phase and allowing the patient to sleep and eat as needed in later phases. Refer to psychotherapy or behavioral therapy once stable.
Depressants			
Sedative-Hypnotics			
Barbiturates: secobarbital (Seconal), pentobarbital (Nembutal), amobarbital (Amytal) *Benzodiazepines:* diazepam (Valium), chlordiazepoxide (Librium), alprazolam (Xanax) *Nonbarbiturates-nonbenzodiazepines:* methaqualone (Quaalude), chloral hydrate (Somnote)	Initial relaxation, emotional lability, decreased inhibitions, drowsiness, lack of coordination, impaired judgment, slurred speech, hypotension, bradycardia, bradypnea, constricted pupils	*Early:* Weakness, restlessness, insomnia, hyperthermia, orthostatic hypotension, confusion, disorientation *Days 3-5:* Major convulsive episodes, psychotic delirium, exhaustion, cardiovascular collapse, death	Stabilize on phenobarbital or a long-acting benzodiazepine. Gradually taper dose after stabilization. Supportive care includes measures to ensure patient safety and comfort, frequent assessment of neurologic status and vital signs, and provision of reassurance and orientation. Motivate the patient to engage in long-term treatment and refer to psychotherapy or behavioral therapy once stable.
Opioids			
Heroin (street names: brown sugar, dope, horse, junk, mud, smack), morphine, opium, codeine, fentanyl (Sublimaze), meperidine (Demerol), hydromorphone (Dilaudid), pentazocine (Talwin), oxycodone (OxyContin), methadone (Dolophine)	Analgesia, euphoria, drowsiness, detachment from environment, relaxation, constricted pupils, constipation, nausea, decreased respiratory rate, slurred speech, impaired judgment, decreased sexual and aggressive drives	Watery eyes, dilated pupils, runny nose, yawning, tremors, muscle and joint pain, chills, fever, diaphoresis, insomnia, tachycardia, hypertension, nausea, vomiting, diarrhea, abdominal cramps, food cravings	Methadone in decreasing doses is used during detoxification to decrease symptoms. Symptom management includes bismuth subsalicylate (Kaopectate) for diarrhea, acetaminophen (Tylenol) for muscle aches, and clonidine (Catapres) for generalized symptoms. Once stable, continued use of opioid agonists (methadone), opioid antagonists (naltrexone [ReVia]), or mixed opioid agonists-antagonists (buprenorphine [Subutex, Suboxone]) is recommended under outpatient supervision.
Cannabis			
Marijuana (street names: pot, reefer, weed, herb), hashish (street names: hash, hemp)	Euphoria, sedation, hallucinations	Flulike illness, disturbed sleep, irritability, anxiety, insomnia, tremor, anorexia	No specific drug therapy is effective in treating withdrawal. Supportive care includes measures to ensure patient comfort, including analgesics and hydration. Benzodiazepines are used for symptomatic relief. Refer to psychotherapy or behavioral therapy once stable.

depression. Other complications associated with opioid use are presented in Table 11-2.

NURSING AND COLLABORATIVE CARE
DEPRESSANT ABUSE

OVERDOSE

Unintentional overdose frequently occurs with recreational use of depressants because of the unpredictability in potency and purity. If the patient has ingested multiple substances, a complex and potentially confusing clinical picture can result. Serum and urine drug screens may be helpful in identifying the type and amounts of drugs present in the body. The first priority of care in overdose is always the patient's ABCs. Continuous monitoring of neurologic status, including level of consciousness, and respiratory and cardiovascular function is critical until the patient is stable.[15] Emergency management of depressant drug overdose is presented in Table 11-12.

SEDATIVE-HYPNOTICS. Overdoses of benzodiazepines are treated with flumazenil (Romazicon), a specific benzodiazepine antagonist. Flumazenil is used with caution because it can cause seizures in patients with physical dependence on benzodiaze-

FIG. 11-3 Use of oxycodone injections has increased rapidly. (Doug Menuez/Photodisc/Thinkstock)

pines. Because flumazenil may have a shorter duration of action than some benzodiazepines, doses may need to be repeated until the benzodiazepine is metabolized.

There are no known antagonists to counteract the effects of barbiturates or other sedative-hypnotic drugs. The patient who has overdosed on sedative-hypnotics other than benzodiazepines must be treated aggressively. Dialysis may be required to decrease the drug level and to prevent irreversible CNS depressant effects and death. Gastric lavage and administration of activated charcoal may be instituted if the drug was taken orally within the previous hour. CNS stimulants are avoided, since their use is associated with higher mortality rates.

OPIOIDS. A patient with an opioid overdose can be seen at the emergency department in a coma and respiratory arrest. A toxicologic blood or urine screen may be helpful to identify the specific drug, but treatment is not delayed for toxicology results. Death can occur if the overdose is not treated. An opioid antagonist such as naloxone (Narcan) should be given as soon as life support is instituted. Monitor the patient closely because naloxone has a shorter duration of action than most opioids. The patient may have a mixed drug ingestion that does not respond to opioid antagonists.

TABLE 11-11 EMERGENCY MANAGEMENT

Cocaine and Amphetamine Toxicity

Assessment Findings	Interventions
Cardiovascular • Palpitations • Tachycardia • Hypertension • Dysrhythmias • Myocardial ischemia or infarction	• Ensure patent airway. • Anticipate need for intubation if respiratory distress evident. • Establish IV access and initiate fluid replacement as appropriate. • Obtain a 12-lead ECG and initiate ECG monitoring. • Treat ventricular dysrhythmias as appropriate with lidocaine, bretylium (Bretylol), or procainamide (Pronestyl). • Hypertension and chest pain may require administration of nitroprusside (Nipride) or phentolamine (Regitine). • Aspirin may be administered to lower the risk of myocardial infarction. • Administer IV diazepam (Valium) or lorazepam (Ativan) for seizures. • Administer IV antipsychotic drugs for psychosis and hallucinations. • Naloxone (Narcan) IV should be given if CNS depression is present and concurrent opioid use is suspected. • Monitor vital signs and level of consciousness. • Initiate cooling measures for hyperthermia.
Central Nervous System • Feeling of impending doom • Euphoria • Agitation • Combativeness • Seizures • Hallucinations • Confusion • Paranoia • Fever	
Other • Track marks • Consumption of bags of cocaine	

TABLE 11-12 EMERGENCY MANAGEMENT

Depressant Drug Overdose

Assessment Findings	Interventions
• Aggressive behavior • Agitation • Confusion • Lethargy • Stupor • Hallucinations • Depression • Slurred speech • Pinpoint pupils • Nystagmus • Seizures • Needle tracks • Cold, clammy skin • Rapid, weak pulse • Slow or rapid shallow respirations • Decreased oxygen saturation • Hypotension • Dysrhythmias • ECG changes • Cardiac or respiratory arrest	• Ensure patent airway. • Anticipate intubation if respiratory distress evident. • Establish IV access. • Obtain temperature. • Obtain 12-lead ECG and initiate continuous ECG monitoring. • Obtain information about substance (name, route, when taken, amount). • Obtain specific drug levels or comprehensive toxicology screen. • Obtain a health history, including drug use and allergies. • Administer antidotes as appropriate. • Perform gastric lavage if necessary. • Administer activated charcoal and cathartics as appropriate. • Monitor vital signs, level of consciousness, and oxygen saturation.

WITHDRAWAL

SEDATIVE-HYPNOTICS. Withdrawal from sedative-hypnotics can be life threatening. The manifestations are nearly identical to those of alcohol withdrawal (see Table 11-8). Because the patient may experience delirium, seizures, and respiratory and cardiac arrest within 24 hours after the last dose, close monitoring in an inpatient setting is often required[16] (see Table 11-10). Mild to moderate symptoms can persist for 2 to 3 weeks after a 3- to 5-day period of acute symptoms.

OPIOIDS. Withdrawal from opioids occurs with decreased amounts or cessation of the drug after prolonged moderate to heavy use. The administration of an opioid antagonist, such as naloxone, will also cause withdrawal symptoms in dependent individuals. Symptoms of withdrawal are not usually life threatening but can be severe, depending on the potency of the abused opioid, route of administration, and duration of use (see Table 11-10). Treatment is based on symptoms and may require the use of medications. Methadone (Dolophine) in decreasing doses is the drug used most often during detoxification to decrease symptoms.

CANNABIS

Cannabis, called marijuana or hashish, is the most widely used illicit drug in North America.[1] Patterns of use are similar to those of alcohol in that there is occasional use, misuse resulting in temporary problems, and abuse or dependence associated with a high potential for future problems.

The key active ingredient in cannabis responsible for most of the psychoactive effects is tetrahydrocannabinol (THC). Two THC preparations, dronabinol (Marinol) and nabilone (Cesamet), are available by prescription to control nausea and vomiting resulting from cancer chemotherapy. Dronabinol may also be used to stimulate the appetite in patients with acquired immunodeficiency syndrome (AIDS). Some states have legalized marijuana use for specified health problems. At low to moderate doses, THC produces fewer physiologic and psychologic alterations than do other classes of psychoactive drugs, including alcohol. Health problems caused by heavy use are identified in Table 11-2.

In the patient with acute marijuana intoxication, perform a physical examination and a thorough history. An individual with marijuana intoxication is seldom hospitalized. Panic, flashbacks, and toxic reactions related to the use of marijuana are managed by providing a quiet environment and supporting and reassuring the patient by explaining what is happening. The patient needs to understand that the level of intoxication may fluctuate over several days as metabolites are released.

You may identify withdrawal symptoms in a patient dependent on cannabis who is hospitalized for other health problems. Withdrawal usually causes few physical symptoms, but some patients have flu-like illness, disturbed sleep, and tremors[17] (see Table 11-10). Treatment is supportive.

NURSING MANAGEMENT SUBSTANCE ABUSE

NURSING ASSESSMENT

Any patient with substance dependence who is hospitalized for any condition can develop withdrawal syndrome when the ingestion of the substance is abruptly stopped. Early recognition and identification of withdrawal syndrome are crucial to successful treatment outcomes for any health problem. Hospitalization also provides a chance to address substance use, and for many patients, controlling their health problems requires addressing their substance use.

Question every patient about the use of all substances, including prescribed medications, OTC drugs, caffeine, tobacco, and recreational drugs. Screen for alcohol use using a validated screening questionnaire. Although a variety of screening tools are available, one culturally sensitive tool that is easily used by nurses to identify alcohol dependence is the Alcohol Use Disorders Identification Test (AUDIT) (Table 11-13). A score of 8 points or less is considered nonalcoholic, whereas 9 points or above indicates alcoholism. Another frequently used instrument is the Drug Abuse Screening Test (DAST-10) questionnaire (Table 11-14).

Take a history in a setting that ensures privacy and avoids interruption. To obtain accurate information, use open and nonjudgmental communication with the patient. Ask questions in a way that lets the patient know that you find a behavior normal or at least understandable. You might say, "Given your situation, I wonder if you have been using anything to help relieve your stress." You may also collect a history from any available collateral sources (e.g., spouse) because patients often underreport or minimize their alcohol and drug use.

Reassure the patient that all information will remain confidential and will be used only to provide safe care. The substance-abusing patient may be afraid of losing control of drug administration and may be concerned that substance use will be reported to legal authorities. Inform the patient that federal privacy laws prohibit nurses and other health care providers from disclosing any treatment of substance abuse without the patient's specific written consent.

TABLE 11-13 ALCOHOL USE DISORDERS IDENTIFICATION TEST (AUDIT)

Please answer each question by checking one of the circles in the second column.		**Score**
1. How often do you have a drink containing alcohol?	○ Never	(0)
	○ Monthly or less	(1)
	○ 2-4 times per month	(2)
	○ 2-4 times per week	(3)
	○ 4+ times per week	(4)
2. How many drinks containing alcohol do you have on a typical day when you are drinking?	○ 1 or 2	(0)
	○ 3 or 4	(1)
	○ 5 or 6	(2)
	○ 7 to 9	(3)
	○ 10 or more	(4)
3. How often do you have six or more drinks on one occasion?	○ Never	(0)
	○ Less than monthly	(1)
	○ Monthly	(2)
	○ Weekly	(3)
	○ Daily or almost daily	(4)
4. How often during the last year have you found that you were not able to stop drinking once you had started?	○ Never	(0)
	○ Less than monthly	(1)
	○ Monthly	(2)
	○ Weekly	(3)
	○ Daily or almost daily	(4)
5. How often in the last year have you failed to do what was normally expected of you because you were drinking?	○ Never	(0)
	○ Less than monthly	(1)
	○ Monthly	(2)
	○ Weekly	(3)
	○ Daily or almost daily	(4)
6. How often during the last year have you needed a first drink in the morning to get yourself going after a heavy drinking session?	○ Never	(0)
	○ Less than monthly	(1)
	○ Monthly	(2)
	○ Weekly	(3)
	○ Daily or almost daily	(4)
7. How often during the last year have you had a feeling of guilt or remorse about drinking?	○ Never	(0)
	○ Less than monthly	(1)
	○ Monthly	(2)
	○ Weekly	(3)
	○ Daily or almost daily	(4)
8. How often during the last year have you been unable to remember what happened the night before because you had been drinking?	○ Never	(0)
	○ Less than monthly	(1)
	○ Monthly	(2)
	○ Weekly	(3)
	○ Daily or almost daily	(4)
9. Have you or someone else been injured as a result of your drinking?	○ No	(0)
	○ Yes, but not in the last year	(2)
	○ Yes, during the last year	(4)
10. Has a relative, friend, or other health worker been concerned about your drinking or suggested that you cut down?	○ No	(0)
	○ Yes, but not in the last year	(2)
	○ Yes, during the last year	(4)

Scoring for AUDIT: Questions 1 through 8 are scored 0, 1, 2, 3, or 4. Questions 9 and 10 are scored 0, 2, or 4 only. The minimum score (nondrinkers) is 0 and the maximum possible score is 40. A score of 9 or more indicates hazardous or harmful alcohol consumption.

TABLE 11-14 DRUG ABUSE SCREENING TEST (DAST-10)

In the last 12 months:

1. Have you used drugs other than those required for medical reasons?	No	Yes
2. Do you abuse more than one drug at a time?	No	Yes
3. Are you always able to stop using drugs when you want to?	No	Yes
4. Have you had "blackouts" or "flashbacks" as a result of drug use?	No	Yes
5. Do you ever feel bad or guilty about your drug use?	No	Yes
6. Does your spouse (or parents) ever complain about your involvement with drugs?	No	Yes
7. Have you neglected your family because of your use of drugs?	No	Yes
8. Have you engaged in illegal activities in order to obtain drugs?	No	Yes
9. Have you ever experienced withdrawal symptoms or felt sick when you stopped taking drugs?	No	Yes
10. Have you had medical problems as a result of your drug use?	No	Yes

TABLE 11-15 SIGNS SUGGESTING SUBSTANCE ABUSE

- Fatigue
- Insomnia
- Headaches
- Seizure disorder
- Changes in mood
- Anorexia, weight loss
- Vague physical complaints
- Overabundant use of mouthwash or toiletries
- Appearing older than stated age, unkempt appearance
- Leisure activities that involve alcohol and/or other drugs
- Sexual dysfunction, decreased libido, erectile dysfunction
- Trauma secondary to falls, auto accidents, fights, or burns
- Driving while intoxicated (more than one citation suggests dependence)
- Failure of standard doses of sedatives to have a therapeutic effect
- Financial problems, including those related to spending for substances
- Defensive or evasive answers to questions about substance use and its importance in the person's life
- Problems in areas of life function (e.g., frequent job changes; marital conflict, separation, or divorce; work-related accidents, tardiness, absenteeism; legal problems; social isolation, estrangement from friends or family)

During your assessment, observe for patient behaviors that influence history taking such as denial, avoidance, underreporting or minimizing of substance use, or provision of inaccurate information. Possible behaviors and physical complaints suggesting substance dependence are listed in Table 11-15, but these behaviors are not all-inclusive. Even if a patient denies addiction or dependence, if there is any indication of alcohol or other CNS depressant use when a patient is hospitalized, always ask when the patient last used the substance. This information will help you anticipate drug interactions or the time of possible onset of withdrawal symptoms if the patient is indeed dependent on a substance.

Problems associated with substance abuse are often revealed through physical assessment, including assessment of the patient's general appearance and nutritional status and examination of the abdomen; the skin; and the cardiovascular, respiratory, and neurologic systems. Urine and blood drug screenings may be performed in some situations to determine drug use. A complete blood count, serum electrolytes, blood urea nitrogen, creatinine, and hepatic function tests may be done to evaluate for electrolyte imbalances or kidney or liver dysfunction.

NURSING DIAGNOSES

Nursing diagnoses for an individual with substance abuse may include, but are not limited to, those presented in NCP 11-1.

PLANNING

The overall goals are that the patient with a substance abuse problem will (1) have normal physiologic functioning, (2) acknowledge a substance abuse problem, (3) explain the psychologic and physiologic effects of substance use, (4) abstain from the use of addicting substances, and (5) cooperate with a proposed treatment plan.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Your role in health promotion includes prevention and early detection of substance abuse. Teaching about the effects and negative outcomes of substance abuse is essential in preventing this problem. When individuals have substance abuse problems, it is critical to motivate them to enter treatment programs.

ACUTE INTERVENTION. Acute intoxication, overdose, and withdrawal may be seen in acute care situations. Intoxication and overdose may require physiologic support until detoxification can occur. During detoxification the patient is treated to diminish or remove drugs or their effects from the body. Treatments may involve administration of antagonistic drugs, promotion of metabolism and elimination of the drug, or intensive supportive care until the drug is naturally eliminated. Be aware that intoxication and overdose could occur in a hospitalized patient dependent on substances if visitors provide the substances.

You are in a unique position to motivate and facilitate behavior change in people who are abusing substances. When patients seek care for health problems related to substance abuse or when hospitalization interferes with the patient's usual pattern of substance use, the patient's awareness of a substance abuse problem is increased. Intervention by nurses at this time can be a crucial factor in promoting behavior change. Take an active role in performing motivational interviewing and providing counseling aimed at promoting cessation. Document all the interventions in the patient's chart.

AMBULATORY AND HOME CARE. Before treatment and rehabilitation for substance abuse are considered, acute health problems must be resolved. Many of the patients with substance abuse problems that you encounter in hospitals and primary care centers seek care for health problems associated with substance abuse, not for their addiction itself. When you are working in a medical-surgical setting, you usually will not be involved in long-term treatment of patients with substance abuse problems. However, it is your responsibility to identify the problem, motivate the patient to change behavior, and be prepared to refer the patient to inpatient and outpatient programs in the community that provide treatment and rehabilitation. Failure to confront

the patient's substance abuse problem, thus enabling the behavior, is a breach of your professional responsibility.

GERONTOLOGIC CONSIDERATIONS

SUBSTANCE ABUSE

Health care providers are much less likely to recognize substance misuse, abuse, and dependence in older adults than in younger adults. Older adults do not fit the image of abusers. In addition, their patterns of misuse of prescription psychoactive agents and alcohol are less commonly seen than those of younger populations. Because the effects of alcohol and drug use can be mistaken for medical conditions common among older adults, such as insomnia, depression, poor nutrition, heart failure, and frequent falls, the substance abuse problem is often not diagnosed and not treated.[18]

Older adults' misuse and abuse of psychoactive agents, either alone or in combination, may cause confusion, disorientation, delirium, memory loss, and neuromuscular impairment. Physiologic changes that accompany aging, such as decreased circulation, metabolism, and excretion, may lead to intoxication at levels that may not have been a problem at a younger age. Withdrawal symptoms that occur in the older adult when alcohol, opioids, or sedative-hypnotics are abruptly stopped may be more severe than in younger individuals. Always consider that behavior changes in older adults may be caused by substance use or withdrawal.

Identification of substance misuse, abuse, and dependence in older adults presents a challenge. Family members are important sources of information. As with all patients, it is important for you to discuss all drug and alcohol use with older adult patients, including OTC, herbal, and homeopathic drug use. Assess the patient's knowledge of medications that are currently being taken.

The older adult may not exhibit the social, legal, and occupational consequences of substance abuse identified by common screening questionnaires. However, the Short Michigan Alcoholism Screening Test–Geriatric Version (SMAST-G) has been developed as a short-form alcoholism-screening instrument for older adults.[19] This tool, available at *http://consultgerirn.org*, can identify those at risk for negative outcomes of alcohol use. The AUDIT and DAST-10 questionnaires (discussed previously) can also be used with or instead of the SMAST-G to identify alcohol and drug abuse or dependence in older adults.

Smoking and other tobacco use is also an issue in older adults. Older adults who have been chronic smokers for decades may feel unable to stop, or they may believe there is no benefit to stopping at an advanced age. However, smoking contributes to and exacerbates many chronic illnesses found in the older adult population. Smoking cessation at any age is beneficial. The clinical practice guideline for treating tobacco use and dependence discussed earlier is appropriate for helping older adults with smoking cessation (see Tables 11-3 to 11-6).

Patient teaching for the older adult includes teaching about the desired effects, possible side effects, and appropriate use of prescribed and OTC drugs. Advise patients not to drink alcohol when using prescribed and OTC drugs. If no medical condition or possible drug interactions preclude the use of alcohol, advise older patients to limit their alcohol intake to one drink per day. When you suspect alcohol or substance dependence in the older patient, refer the patient for treatment. It is a mistaken belief that older people have little to gain from alcohol and drug dependence treatment. The rewards of treatment can lead to greater quality and quantity of life for older adults.

CASE STUDY

Substance Misuse and Abuse

iStockphoto/Thinkstock

Patient Profile

C.M., a 78-year-old white woman, is admitted to the emergency department after falling and injuring her right hip. She has been widowed for 4 years and lives alone. Recently her best friend died. Her only family is a daughter who lives out of town. When contacted by phone, the daughter tells the nurse that her mother has appeared more disoriented and confused over the past few months when she has talked to her on the phone.

Subjective Data

- Is complaining of severe pain in her right hip
- Admits she had some wine in the late afternoon to stimulate her appetite
- Has experienced several falls in the past 2 months
- Reports that she fell after taking her sleeping pill prescribed by her physician because she does not sleep well
- Speech is hesitant and slurred
- Says she smokes about one-half pack of cigarettes a day

Objective Data

Physical Examination

- Oriented to person and place, but not time
- BP 162/94, pulse 92, respirations 24
- Severe pain and tenderness in the right hip region
- Tremors of hands

Diagnostic Tests

- X-ray reveals a subtrochanteric fracture of the right femur requiring surgical repair
- Blood alcohol concentration (BAC) 120 mg/dL (0.12 mg%)
- Complete blood count: hemoglobin 10.6 g/dL, hematocrit 33%

Discussion Questions

1. What other information is needed to assess C.M.'s condition?
2. How should questions regarding substance use be addressed?
3. What factors may contribute to C.M.'s use of psychoactive substances?
4. ***Priority Decision:*** What are the priority nursing interventions during C.M.'s preoperative period?
5. What possible complications and other health problems may become apparent during C.M.'s postoperative recovery?
6. ***Priority Decision:*** What are the priority nursing interventions after C.M.'s surgery?
7. ***Delegation Decision:*** How would you use the following nursing personnel on the postoperative unit to carry out the priority interventions that you identified in question 6: registered nurse (RN), licensed practical nurse (LPN), unlicensed assistive personnel (UAP)?
8. ***Priority Decision:*** Based on the assessment data presented, what are the priority nursing diagnoses? Are there any collaborative problems?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A person who injects heroin to experience the euphoria that it causes is demonstrating
   - **a.** abuse.
   - **b.** addiction.
   - **c.** tolerance.
   - **d.** addictive behavior.
2. When admitting a patient, the nurse must assess the patient for substance use based on the knowledge that long-term use of addictive substances leads to
   - **a.** the development of coexisting psychiatric illnesses.
   - **b.** a higher risk for complications from underlying health problems.
   - **c.** increased availability of dopamine, resulting in decreased sleep requirements.
   - **d.** potentiation of effects of similar drugs taken when the individual is drug free.
3. The nurse would suspect cocaine overdose in the patient who is experiencing
   - **a.** craving, restlessness, and irritability.
   - **b.** agitation, cardiac dysrhythmias, and seizures.
   - **c.** diarrhea, nausea and vomiting, and confusion.
   - **d.** slow, shallow respirations; hyporeflexia; and blurred vision.
4. The most appropriate nursing intervention for a patient who is being treated for an acute exacerbation of chronic obstructive pulmonary disease who is not interested in quitting smoking is to
   - **a.** accept the patient's decision and not intervene until the patient expresses a desire to quit.
   - **b.** realize that some smokers will never quit, and trying to assist them increases the patient's' frustration.
   - **c.** motivate the patient to quit by describing how continued smoking will worsen the breathing problems.
   - **d.** ask the patient to identify the relevance, risks, and benefits of quitting and what barriers to quitting are present.
5. While caring for a patient who is experiencing alcohol withdrawal, the nurse should *(select all that apply)*
   - **a.** monitor neurologic status on a routine basis.
   - **b.** provide a quiet, nonstimulating, dimly lit environment.
   - **c.** pad the side rails and place suction equipment at the bedside.
   - **d.** orient the patient to environment and person with each contact.
   - **e.** administer antiseizure drugs and sedatives to relieve symptoms during withdrawal.
6. Substance abuse problems in older adults are usually related to
   - **a.** use of drugs and alcohol as a social activity.
   - **b.** misuse of prescribed and over-the-counter drugs and alcohol.
   - **c.** continuing the use of illegal drugs initiated during middle age.
   - **d.** a pattern of binge drinking for weeks or months with periods of sobriety.

1. d, 2. b, 3. b, 4. d, 5. a, c, d, e, 6. b

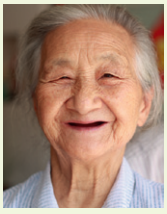
MANAGING MULTIPLE PATIENTS

Introduction

You are assigned to care for the following five patients on a medical-surgical unit. Your team consists of yourself, a new LPN still on orientation, and an unlicensed assistive personnel (UAP).

Patients



iStockphoto/Thinkstock

A.Z. is a 75-year-old woman who came to the United States from Russia 10 years ago with her daughter, her son-in-law, and their five children. She speaks minimal English, relying on her oldest granddaughter to translate. A.Z., who has a history of diabetes mellitus, was admitted to the hospital yesterday with a diagnosis of heart failure.

Thomas M. Perkins/ Shutterstock.com

M.L. is a 60-year-old Asian woman who was admitted to the hospital with a diagnosis of exacerbation of chronic obstructive pulmonary disease (COPD). She is receiving oxygen at 2 L/min via nasal cannula and her condition is currently stable.

iStockphoto/Thinkstock

L.X. is a 79-year-old Chinese woman who was admitted through the emergency department with a chief complaint of shortness of breath. She was diagnosed with community-acquired pneumonia, which is being treated with IV antibiotics.

Ryan McVay/Photodisc/ Thinkstock

K.C. is a 280-lb (127-kg) 68-year-old African American woman with diabetes who was admitted for an incision and drainage of a right abdominal abscess. She is being discharged on her second postoperative day. Her married daughter will assist with dressing changes at home.

iStockphoto/Thinkstock

C.M. is a 78-year-old white woman who was admitted from the emergency department after falling and fracturing her right hip. She is in Buck's traction and is scheduled to undergo surgical repair later this morning. She has a history of substance abuse and her blood alcohol content (BAC) was 120 mg/dL (0.12 mg%) on admission. The night nurse reports that she has been somewhat confused and restless overnight.

Management Discussion Questions

1. ***Priority Decision:*** After receiving report, which patient should you see first? Provide rationale.
2. ***Delegation Decision:*** Which morning task(s) could you delegate to the LPN *(select all that apply)?*
   a. Obtain a capillary blood glucose reading on K.C.
   b. Assess L.X.'s IV site for signs of phlebitis or infiltration.
   c. Access the hospital's available translation services for A.Z.
   d. Titrate M.L.'s oxygen to obtain a pulse oximetry reading of 95%, as ordered by the health care provider.
3. ***Priority and Delegation Decision:*** When you and the LPN enter A.Z.'s room, you find the patient sitting up in bed with labored respirations. Although you cannot understand what she is saying, you note that she is unable to say more than two words without stopping for a breath. Which initial action would be the most appropriate?
   a. Ask the LPN to get A.Z.'s vital signs while you auscultate her lung sounds.
   b. Administer A.Z.'s cardiac and respiratory medications and reassess her in 30 minutes.
   c. Have the LPN find A.Z.'s granddaughter so that she can translate what A.Z. is trying to tell you.
   d. Ask the LPN to stay with A.Z. while you go to the nurse's station to call A.Z.'s health care provider.

Case Study Progression

A.Z.'s assessment reveals bibasilar crackles, 2+ dependent pitting edema, BP 175/84, pulse 96, RR 32, temp 36.8° C, and pulse oximetry 88% on room air. You administer oxygen at 2 L/min via nasal cannula and obtain an order from A.Z.'s health care provider for furosemide 40 mg IV stat. After administering the diuretic, A.Z.'s granddaughter arrives and you discuss her grandmother's condition. She tells you that her grandmother asked her to bring in potato chips and soda yesterday. She did not think her grandmother should be eating salt, but A.Z. insisted that the dietitian said that she could eat them.

4. On further investigation, the dietitian tells you that a translator was not available when she saw A.Z. yesterday. Because the dietitian did not understand what the patient was saying, she could not respond to any of her questions. She planned to visit A.Z. today when the granddaughter is present. Being a culturally competent nurse, you realize that A.Z. most likely interpreted the dietitian's silence as
   a. agreement with what A.Z. was asking.
   b. demonstrating a lack of respect for A.Z.'s wishes.
   c. a lack of understanding by the dietitian as to what she was asking.
   d. a need for the dietitian to get more information before answering her questions.
5. Which assessment findings might suggest elder mistreatment by L.X.'s son, with whom she lives *(select all that apply)?*
   a. Two sacral ulcers
   b. Asking when her son is coming to visit
   c. Multiple small bruises on her forearms and shins
   d. Matted hair, poor oral hygiene, overgrown toenails
6. Knowing that C.M.'s reported restlessness overnight may indicate acute alcohol withdrawal, you perform a more thorough assessment. Your assessment reveals a score of 11 on the Clinical Institute Withdrawal Assessment for Alcohol Scale. To prevent alcohol delirium, you plan to administer
   a. IV thiamine.
   b. morphine sulfate.
   c. naloxone (Narcan).
   d. lorazepam (Ativan).
7. ***Management Decision:*** The UAP informs you that the LPN is not following hospital protocol when caring for patients at risk for falling. What is your most appropriate action?
   a. Notify the unit manager as soon as possible.
   b. Ask the UAP to explain hospital protocol to the LPN.
   c. Write up the LPN's actions so they are included in her evaluation.
   d. Talk to the LPN about the importance of following hospital protocol to prevent injury in patients at risk for falling.

LEARNING OUTCOMES

1. Describe the inflammatory response, including vascular and cellular responses and exudate formation.
2. Explain local and systemic manifestations of inflammation and their physiologic bases.
3. Describe the drug therapy, nutrition therapy, and nursing management of inflammation.
4. Differentiate among healing by primary, secondary, and tertiary intention.
5. Describe the factors that delay wound healing and common complications of wound healing.
6. Describe the nursing and collaborative management of wound healing.
7. Explain the etiology and clinical manifestations of pressure ulcers.
8. Apply a patient risk assessment for pressure ulcers to measures used to prevent the development of pressure ulcers.
9. Discuss nursing and collaborative management of a patient with pressure ulcers.

This chapter focuses on inflammation and wound healing. Pressure ulcer prevention and treatment are also described.

INFLAMMATORY RESPONSE

The **inflammatory response** is a sequential reaction to cell injury. It neutralizes and dilutes the inflammatory agent, removes necrotic materials, and establishes an environment suitable for healing and repair. The term *inflammation* is often but incorrectly used as a synonym for the term *infection*. Inflammation is always present with infection, but infection is not always present with inflammation. However, a person who is neutropenic may not be able to mount an inflammatory response. An infection involves invasion of tissues or cells by microorganisms such as bacteria, fungi, and viruses. In contrast, inflammation can also be caused by heat, radiation, trauma, chemicals, allergens, and an autoimmune reaction.

The mechanism of inflammation is basically the same regardless of the injuring agent. The intensity of the response depends on the extent and severity of injury and on the injured person's reactive capacity. The inflammatory response can be divided into a vascular response, a cellular response, formation of exudate, and healing. Fig. 12-1 illustrates the vascular and cellular response to injury.

Reviewed by Trevah A. Panek, RN, MSN, CCRN, Assistant Professor of Nursing, Saint Francis University, Loretto, Pennsylvania; and Clemma K. Snider, RN, MSN, Assistant Professor, Associate Degree Nursing, Eastern Kentucky University, Richmond, Kentucky.

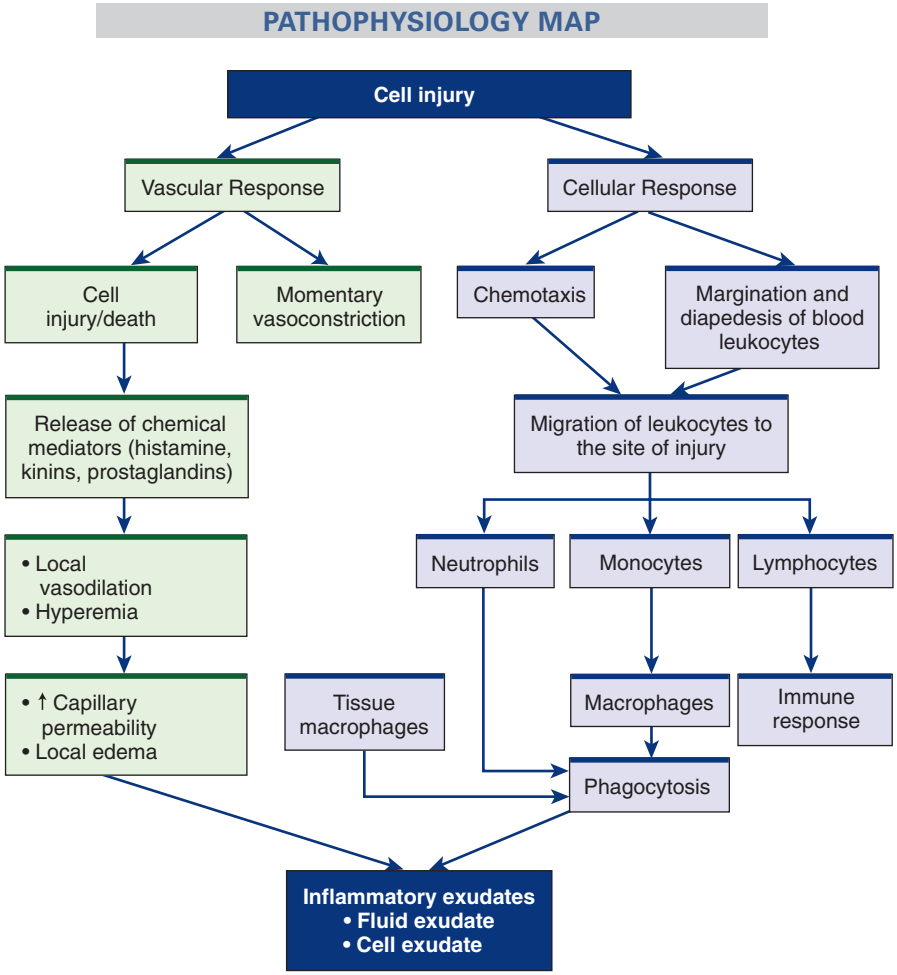

FIG. 12-1 Vascular and cellular responses to tissue injury.

Vascular Response

After cell injury, local arterioles briefly undergo transient vasoconstriction. After release of histamine and other chemicals by the injured cells, the vessels dilate. Chemical mediators cause increased capillary permeability and facilitate fluid movement from capillaries into tissue spaces. Initially composed of serous fluid, this inflammatory exudate later contains plasma proteins, primarily albumin. These proteins exert oncotic pressure that further draws fluid from blood vessels. Both vasodilation and increased capillary permeability are responsible for redness, heat, and swelling at the site of injury.

As the plasma protein fibrinogen leaves the blood, it is activated to fibrin by the products of the injured cells. Fibrin strengthens a blood clot formed by platelets. In tissue the clot functions to trap bacteria, prevent their spread, and serve as a framework for the healing process. Platelets release growth factors that start the healing process.

Cellular Response

Neutrophils and monocytes move from circulation to the site of injury (see Fig. 12-1). *Chemotaxis* is the directional migration of white blood cells (WBCs) to the site of injury, resulting in an accumulation of neutrophils and monocytes at the site. (eFig. 12-1 showing chemotaxis is available on the website for this chapter.)

Neutrophils. Neutrophils are the first leukocytes to arrive at the injury site (usually within 6 to 12 hours). They phagocytize (engulf) bacteria, other foreign material, and damaged cells. With their short life span (24 to 48 hours), dead neutrophils soon accumulate. In time a mixture of dead neutrophils, digested bacteria, and other cell debris accumulates as a creamy substance termed *pus*.

To keep up with the demand for neutrophils, the bone marrow releases more neutrophils into circulation. This results in an elevated WBC count, especially the neutrophil count. Sometimes the demand for neutrophils increases to the extent that the bone marrow releases immature forms of neutrophils *(bands)* into circulation. (Mature neutrophils are called segmented neutrophils.) The finding of increased numbers of band neutrophils in circulation is called a *shift to the left,* which is commonly found in patients with acute bacterial infections. (See Chapter 30 for a discussion of neutrophils.)

Monocytes. Monocytes are the second type of phagocytic cells that migrate from circulating blood. They usually arrive at the site within 3 to 7 days after the onset of inflammation. On entering the tissue spaces, monocytes transform into macrophages. Together with the tissue macrophages, these newly arrived macrophages assist in phagocytosis of the inflammatory debris. The macrophage role is important in cleaning the area before healing can occur. Macrophages have a long life span;

TABLE 12-1 MEDIATORS OF INFLAMMATION

Mediator	Source	Mechanisms of Action
Histamine	Stored in granules of basophils, mast cells, platelets	Causes vasodilation and increased capillary permeability.
Serotonin	Stored in platelets, mast cells, enterochromaffin cells of GI tract	Same as above. Stimulates smooth muscle contraction.
Kinins (e.g., bradykinin)	Produced from precursor factor kininogen as a result of activation of Hageman factor (XII) of clotting system	Cause contraction of smooth muscle and vasodilation. Result in stimulation of pain.
Complement components (C3a, C4a, C5a)	Anaphylatoxic agents generated from complement pathway activation	Stimulate histamine release and chemotaxis.
Prostaglandins (PGs) and leukotrienes (LTs)	Produced from arachidonic acid (see Fig. 12-2)	PGs cause vasodilation. LTs stimulate chemotaxis.
Cytokines	For information on cytokines, see Table 14-3	

they can multiply and may stay in the damaged tissues for weeks. These long-lived cells are important in orchestrating the healing process.

In cases where particles are too large for a single macrophage, the macrophages accumulate and fuse to form a *multinucleated giant cell.* The giant cell is then encapsulated by collagen, leading to the formation of a granuloma. A classic example of this process occurs in tuberculosis of the lung. While the *Mycobacterium* bacillus is walled off, a chronic state of inflammation exists. The granuloma formed is a cavity of necrotic tissue.

Lymphocytes. Lymphocytes arrive later at the site of injury. Their primary role is related to humoral and cell-mediated immunity (see Chapter 14).

Chemical Mediators

Mediators of the inflammatory response are presented in Table 12-1.

Complement System. The complement system is an enzyme cascade (C1 to C9) consisting of pathways to mediate inflammation and destroy invading pathogens. (eFig. 12-2 showing the complement cascade is available on the website for this chapter.) Major functions of the complement system are enhanced phagocytosis, increased vascular permeability, chemotaxis, and cellular lysis. All of these activities are important mediators of the inflammatory response and healing.

Cell lysis occurs when the final components create holes in the cell membranes and cause targeted cell death by membrane rupture. In autoimmune disorders, healthy tissue can be damaged by complement activation and the resulting inflammatory response. Examples of this include rheumatoid arthritis and systemic lupus erythematosus.

Prostaglandins and Leukotrienes. When cells are activated by injury, the arachidonic acid in the cell membrane is rapidly converted to produce prostaglandins (PGs), thromboxane, and leukotrienes (Fig. 12-2). PGs are generally considered proinflammatory and are potent vasodilators contributing to increased blood flow and edema formation.

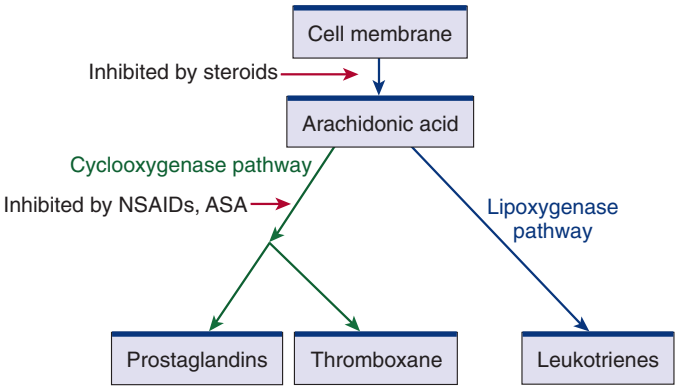

FIG. 12-2 Pathway of generation of prostaglandins, thromboxane, and leukotrienes. Corticosteroids, nonsteroidal antiinflammatory drugs *(NSAIDs),* and acetylsalicylic acid *(ASA)* act to inhibit various steps in this pathway.

Some subtypes of PGs are formed when platelets are activated and can inhibit platelet and neutrophil aggregation. PGs also perform a significant role in sensitizing pain receptors to arousal by stimuli that would normally be painless. PGs have a pivotal role as pyrogens when stimulating the temperature-regulating area of the hypothalamus and producing a febrile response.

Thromboxane is a powerful vasoconstrictor and platelet-aggregating agent. It causes brief vasoconstriction and skin pallor at the injury site and promotes clot formation. It has a short half-life, and the pallor soon gives way to vasodilation and redness, which is caused by PGs and histamine.

Leukotrienes form the slow-reacting substance of anaphylaxis (SRS-A), which constricts smooth muscles of bronchi, causing narrowing of the airway, and increases capillary permeability, leading to airway edema.

Exudate Formation

Exudate consists of fluid and leukocytes that move from the circulation to the site of injury. The nature and quantity of exudate depend on the type and severity of the injury and the tissues involved (Table 12-2).

Clinical Manifestations

The *local response* to inflammation includes the manifestations of redness, heat, pain, swelling, and loss of function (Table 12-3). *Systemic* manifestations of inflammation include an increased WBC count with a shift to the left, malaise, nausea and anorexia, increased pulse and respiratory rate, and fever.

Leukocytosis results from the increased release of WBCs from the bone marrow. Although the causes of other systemic manifestations are poorly understood, they may be related to complement activation and the release of *cytokines* (soluble factors secreted by WBCs and other types of cells that act as intercellular and intracellular messengers). Some of these cytokines (e.g., interleukins [ILs], tumor necrosis factor [TNF]) are important in causing the systemic manifestations of inflammation, as well as inducing fever. An increase in pulse and respiration follows the rise in metabolism as a result of an increase in body temperature. (Cytokines are discussed in Chapter 14.)

Fever. The onset of fever is triggered by the release of cytokines, which cause fever by initiating metabolic changes in the

TABLE 12-2 TYPES OF INFLAMMATORY EXUDATE

Type	Description	Examples
Serous	Results from outpouring of fluid. Seen in early stages of inflammation or when injury is mild.	Skin blisters, pleural effusion
Serosanguineous	Found during the midpoint in healing after surgery or tissue injury. Composed of RBCs and serous fluid, which is semiclear pink and may have red streaks.	Surgical drain fluid
Fibrinous	Occurs with increasing vascular permeability and fibrinogen leakage into interstitial spaces. Excessive amounts of fibrin that coats tissue surfaces may cause them to adhere.	Adhesions, gelatinous ribbons seen in surgical drain tubing Frequently covers fluid-exuding wounds such as venous ulcers
Hemorrhagic	Results from rupture or necrosis of blood vessel walls.	Hematoma, bleeding after surgery or tissue trauma
Purulent (pus)	Consists of WBCs, microorganisms (dead and alive), liquefied dead cells, and other debris.	Furuncle (boil), abscess, cellulitis (diffuse inflammation in connective tissue)
Catarrhal	Found in tissues where cells produce mucus. Mucus production is accelerated by inflammatory response.	Runny nose associated with upper respiratory tract infection

TABLE 12-3 LOCAL MANIFESTATIONS OF INFLAMMATION

Manifestations	Cause
Redness (rubor)	Hyperemia from vasodilation.
Heat (calor)	Increased metabolism at inflammatory site.
Pain (dolor)	Change in pH. Nerve stimulation by chemicals (e.g., histamine, prostaglandins). Pressure from fluid exudate.
Swelling (tumor)	Fluid shift to interstitial spaces. Fluid exudate accumulation.
Loss of function (functio laesa)	Swelling and pain.

temperature-regulating center in the hypothalamus (Fig. 12-3). The synthesis of PGs is the most critical metabolic change. PGs act directly to increase the thermostatic set point. The hypothalamus then activates the autonomic nervous system to stimulate increased muscle tone and shivering and decreased perspiration and blood flow to the periphery. Epinephrine released from the adrenal medulla increases the metabolic rate. The net result is fever.

With the physiologic thermostat fixed at a higher-than-normal temperature, the rate of heat production is increased until the body temperature reaches the new set point. As the set point is raised, the hypothalamus signals an increase in heat

PATHOPHYSIOLOGY MAP

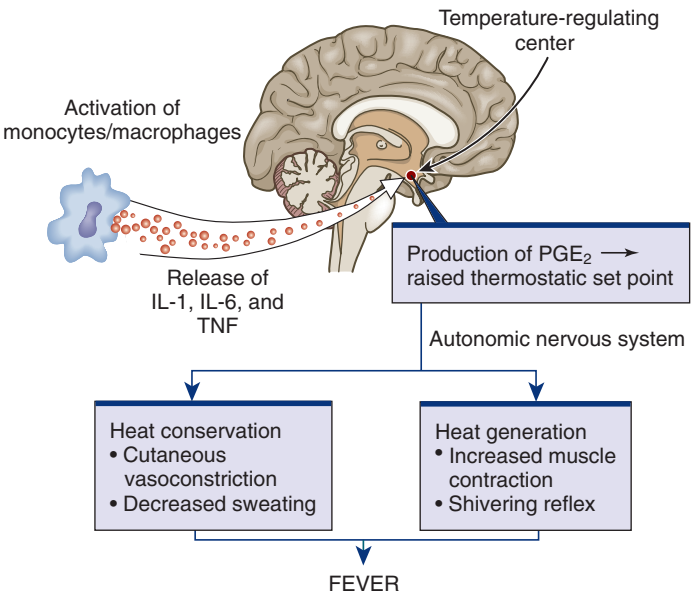

FIG. 12-3 Production of fever. When monocytes/macrophages are activated, they secrete cytokines such as interleukin-1 *(IL-1),* interleukin-6 *(IL-6),* and tumor necrosis factor *(TNF),* which reach the hypothalamic temperature-regulating center. These cytokines promote the synthesis and secretion of prostaglandin E_2 *(PGE_2)* in the anterior hypothalamus. PGE_2 increases the thermostatic set point, and the autonomic nervous system is stimulated, resulting in shivering, muscle contraction, and peripheral vasoconstriction.

production and conservation to raise the body temperature to the new level. At this point the individual feels chilled and shivers. The shivering response is the body's method of raising the body's temperature until the new set point is attained. This seeming paradox is dramatic: the body is hot, yet an individual piles on blankets and may go to bed to get warm. When the body temperature reaches the set point, the chills and warmth-seeking behavior cease.

The released cytokines and the fever they trigger activate the body's defense mechanisms. Beneficial aspects of fever include increased killing of microorganisms, increased phagocytosis by neutrophils, and increased proliferation of T cells. Higher body temperatures may also enhance the activity of interferon, the body's natural virus-fighting substance[1] (see Chapter 14).

Types of Inflammation

The basic types of inflammation are acute, subacute, and chronic. In *acute inflammation* the healing occurs in 2 to 3 weeks and usually leaves no residual damage. Neutrophils are the predominant cell type at the site of inflammation. A *subacute inflammation* has the features of the acute process but lasts longer. For example, infective endocarditis is a smoldering infection with acute inflammation, but it persists for weeks or months (see Chapter 37).

Chronic inflammation lasts for weeks, months, or even years. The injurious agent persists or repeatedly injures tissue. The predominant cell types present at the site of inflammation are lymphocytes and macrophages. Examples of chronic inflammation include rheumatoid arthritis and osteomyelitis. The prolongation and chronicity of any inflammation may be the result of an alteration in the immune response (e.g., autoimmune disease) and can lead to physical deterioration.

NURSING AND COLLABORATIVE MANAGEMENT INFLAMMATION

NURSING IMPLEMENTATION

HEALTH PROMOTION. The best management of inflammation is the prevention of infection, trauma, surgery, and contact with potentially harmful agents. This is not always possible. A simple mosquito bite causes an inflammatory response. Because occasional injury is inevitable, concerted efforts to minimize inflammation and infection are needed.

Adequate nutrition is essential so that the body has the necessary factors to promote healing when injury occurs. A high fluid intake is needed to replace fluid loss from perspiration. There is a 7% increase in metabolism for every 1° F increase in temperature above 100° F (37.8° C), or a 13% increase for every 1° C increase. The increased metabolic rate increases a patient's need for calories.

Early recognition of the manifestations of inflammation is necessary so that appropriate treatment can begin. This may be rest, drug therapy, or specific treatment of the injured site. Immediate treatment may prevent the extension and complications of inflammation.

ACUTE INTERVENTION

Observation and Vital Signs. The ability to recognize the clinical manifestations of inflammation is important. In the individual who is immunosuppressed (e.g., taking corticosteroids or receiving chemotherapy), the classic manifestations of inflammation may be masked. In this individual, early symptoms of inflammation may be malaise or "just not feeling well."

Vital signs are important to note with any inflammation, especially when an infectious process is present. With infection, the temperature may rise, and pulse and respiration rates may increase.

Fever. An important aspect of fever management is determining its cause. Although fever is usually regarded as harmful, an increase in body temperature is an important host defense mechanism. In the seventeenth century, Thomas Sydenham[1] noted that "fever is a mighty engine which nature brings into the world for the conquest of her enemies."

Steps are frequently taken to lower body temperature to relieve the anxiety of the patient and health care professionals. Because mild to moderate fever usually does little harm, imposes no great discomfort, and may benefit host defense mechanisms, antipyretic drugs are rarely essential to patient welfare. Moderate fevers (up to 103° F [39.4° C]) usually produce few problems in most patients. However, if the patient is very young or very old, is extremely uncomfortable, or has a significant medical problem (e.g., severe cardiopulmonary disease, brain injury), the use of antipyretics should be considered. Fever in the immunosuppressed patient should be treated immediately with antibiotic therapy because infections can rapidly progress to septicemia. (Neutropenia is discussed in Chapter 31 on p. 660.)

Fever (especially if greater than 104° F [40° C]) can damage body cells, and delirium and seizures can occur. At temperatures greater than 105.8° F (41° C), regulation by the hypothalamic temperature control center becomes impaired. Damage can occur to many cells, including those in the brain.

Older adults have a blunted febrile response to infection. The body temperature may not rise to the level expected for a younger adult, or the rise may be delayed in its onset. The blunted response can delay diagnosis and treatment. By the time fever (as defined for younger adults) is present, the illness may be more severe. Patients who are taking nonsteroidal antiinflammatory drugs (NSAIDs) on a regular basis (e.g., for treatment of rheumatoid arthritis) may also have a blunted febrile response.

Although sponge baths increase evaporative heat loss, they may not decrease the body temperature unless antipyretic drugs have been given to lower the set point. Otherwise, the body will initiate compensatory mechanisms (e.g., shivering) to restore body heat. The same principle applies to the use of cooling blanket, which are most effective in lowering body temperature when the set point has also been lowered.

A nursing care plan for the patient with a fever (eNursing Care Plan 12-1) is available on the website for this chapter.

Drug Therapy. Drugs are used to decrease the inflammatory response and lower the body temperature (Table 12-4). Aspirin blocks PG synthesis in the hypothalamus and elsewhere in the body. Acetaminophen acts on the heat-regulating center in the hypothalamus. Some NSAIDs (e.g., ibuprofen [Motrin, Advil]) have antipyretic effects. Corticosteroids are antipyretic through the dual mechanisms of preventing both cytokine production and PG synthesis. The action of these drugs results in dilation of superficial blood vessels, increased skin temperature, and sweating.

Antipyretics should be given around the clock to prevent acute swings in temperature. Chills may be evoked or perpetuated by the intermittent administration of antipyretics. These agents cause a sharp decrease in temperature. When the antipyretic wears off, the body may initiate a compensatory involuntary muscular contraction (i.e., chill) to raise the body

TABLE 12-4 DRUG THERAPY

Inflammation and Healing

Drug	Mechanism of Action
Antipyretic Drugs	
Salicylates (aspirin)	Inhibit synthesis of PGs (see Fig. 12-2). Lower temperature by action on heat-regulating center in hypothalamus, resulting in peripheral vasodilation and heat loss
acetaminophen (Tylenol)	Inhibits synthesis of PGs. Lowers temperature by action on heat-regulating center in hypothalamus
NSAIDs (e.g., ibuprofen [Motrin, Advil])	Inhibit synthesis of PGs
Antiinflammatory Drugs	
Salicylates (aspirin)	Inhibit synthesis of PGs, reduce capillary permeability
Corticosteroids (e.g., prednisone)	Interfere with tissue granulation, induce immunosuppressive effects (decreased synthesis of lymphocytes), prevent liberation of lysosomes
NSAIDs (e.g., ibuprofen, piroxicam [Feldene])	Inhibit synthesis of PGs
Vitamins	
Vitamin A	Accelerates epithelialization
Vitamin B complex	Acts as coenzymes
Vitamin C	Assists in synthesis of collagen and new capillaries
Vitamin D	Facilitates calcium absorption

PGs, Prostaglandins.

temperature back up to its previous level. This unpleasant side effect of antipyretic drugs can be prevented by administering these agents regularly at 2- to 4-hour intervals.

Antihistamine drugs may also be used to inhibit the action of histamine. (Antihistamines are discussed in Chapters 14 and 27.)

RICE. **R**est, **i**ce, **c**ompression, and **e**levation (RICE) is a key concept in treating soft tissue injuries and related inflammation.

Rest. Rest helps the body use its nutrients and O_2 for the healing process. The repair process is facilitated by allowing fibrin and collagen to form across the wound edges with little disruption.

Cold and Heat. Cold application is usually appropriate at the time of the initial trauma to promote vasoconstriction and decrease swelling, pain, and congestion from increased metabolism in the area of inflammation. Heat may be used later (e.g., after 24 to 48 hours) to promote healing by increasing the circulation to the inflamed site and subsequent removal of debris. Heat is also used to localize the inflammatory agents. Warm, moist heat may help debride the wound site if necrotic material is present.

Compression and Immobilization. Compression counters the vasodilation effects and development of edema. Compression by direct pressure over a laceration occludes blood vessels and stops bleeding. Compression bandages provide support to injured joints that have tendons and muscles unable to provide support on their own. Assess distal pulses and capillary refill before and after application of compression to evaluate whether compression has compromised circulation (e.g., pale color of skin, loss of feeling).

Immobilization of the inflamed or injured area promotes healing by decreasing the tissues' metabolic needs. Immobilization with a cast or splint supports fractured bones and prevents further tissue injury by sharp bone fragments that could sever nerves or blood vessels (causing hemorrhage). As with compression, evaluate the patient's circulation after application and at regular intervals. Swelling can occur within the closed space of a cast and compromise circulation.

Elevation. Elevating the injured extremity above the level of the heart reduces the edema at the inflammatory site by increasing venous and lymphatic return. Elevation also helps reduce pain associated with blood engorgement at the injury site. Elevation may be contraindicated in patients with significantly reduced arterial circulation.

HEALING PROCESS

The final phase of the inflammatory response is healing. Healing includes two major components: regeneration and repair.

Regeneration

Regeneration is the replacement of lost cells and tissues with cells of the same type. The ability of cells to regenerate depends on the cell type (Table 12-5).

Repair

Repair is healing as a result of lost cells being replaced by connective tissue. Repair is the more common type of healing and usually results in scar formation. Repair is a more complex process than regeneration. Most injuries heal by connective tissue repair. Repair healing occurs by primary, secondary, or tertiary intention (Fig. 12-4).

TABLE 12-5 REGENERATIVE ABILITY OF DIFFERENT TYPES OF TISSUES

Tissues	Cell Type	Description
Skin, lymphoid organs, bone marrow, and mucous membranes	Labile cells	Cells divide constantly. Injury to these organs is followed by rapid regeneration.
Liver, pancreas, kidney, and bone cells	Stable cells	Retain their ability to regenerate but do so only if the organ is injured. Regeneration is slow.
Neurons of the central nervous system (CNS) and skeletal and cardiac muscle cells	Permanent cells	Do not divide. Damage to CNS neurons or skeletal or heart muscle can lead to permanent loss. Healing of skeletal and cardiac muscle will occur by repair with scar tissue. If neurons in the CNS are destroyed, the tissue is generally replaced by glial cells. However, neurogenesis may occur from stem cells (see Chapter 56).

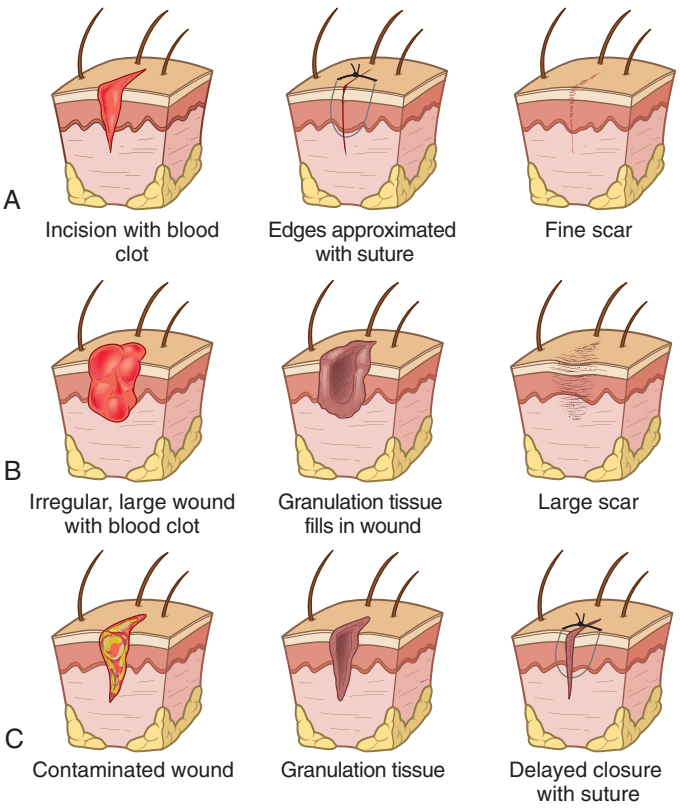

FIG. 12-4 Types of wound healing. **A,** Primary intention. **B,** Secondary intention. **C,** Tertiary intention.

Primary Intention. *Primary intention* healing takes place when wound margins are neatly approximated, as in a surgical incision or a paper cut. A continuum of processes is associated with primary healing (Table 12-6). These processes include three phases.

Initial Phase. In the *initial* (inflammatory) phase, the edges of the incision are first aligned and sutured (or stapled) in place. The incision area fills with blood from the cut blood vessels, blood clots form, and platelets release growth factors to begin

TABLE 12-6 PHASES IN PRIMARY INTENTION HEALING

Phase	Duration	Description
Initial	3-5 days	Approximation of incision edges. Migration of epithelial cells. Clot serving as meshwork for starting capillary growth.
Granulation	5 days to 4 wk	Migration of fibroblasts. Secretion of collagen. Abundance of capillary buds. Wound fragile.
Maturation and scar contraction	7 days to several months	Remodeling of collagen. Strengthening of scar.

the healing process. This forms a matrix for WBC migration. An acute inflammatory reaction occurs.

The area of injury is composed of fibrin clots, erythrocytes, neutrophils (both dead and dying), and other debris. Macrophages ingest and digest cellular debris, fibrin fragments, and red blood cells (RBCs). Extracellular enzymes derived from macrophages and neutrophils help digest fibrin. As the wound debris is removed, the fibrin clot serves as a meshwork for future capillary growth and migration of epithelial cells.

Granulation Phase. The *granulation* phase is the second step. The components of granulation tissue include proliferating fibroblasts; proliferating capillary sprouts *(angioblasts);* various types of WBCs; exudate; and loose, semifluid, ground substance.

Fibroblasts are immature connective tissue cells that migrate into the healing site and secrete collagen. In time the collagen is organized and restructured to strengthen the healing site. At this stage it is termed *fibrous* or *scar tissue.*

During the granulation phase, the wound is pink and vascular. Numerous red granules (young budding capillaries) are present (see eFig. 12-3 available on the website for this chapter). At this point the wound is friable, at risk for dehiscence, and resistant to infection.

Surface epithelium at the wound edges begins to regenerate. In a few days a thin layer of epithelium migrates across the wound surface in a one-cell-thick layer until it contacts cells spreading from the opposite direction. The epithelium thickens and begins to mature, and the wound now closely resembles the adjacent skin. In a superficial wound, re-epithelialization may take 3 to 5 days.

Maturation Phase and Scar Contraction. The maturation phase, during which scar contraction occurs, overlaps with the granulation phase. It may begin 7 days after the injury and continue for several months or years. This is the reason abdominal surgery discharge instructions limit lifting for up to 6 weeks.

Collagen fibers are further organized, and the remodeling process occurs. Fibroblasts disappear as the wound becomes stronger. The active movement of the myofibroblasts causes contraction of the healing area, helping to close the defect and bring the skin edges closer together. A mature scar is then formed. In contrast to granulation tissue, a mature scar is virtually avascular and pale. The scar may be more painful at this phase than in the granulation phase.

Secondary Intention. Wounds that occur from trauma, ulceration, and infection have large amounts of exudate and wide, irregular wound margins with extensive tissue loss. These wounds may have edges that cannot be *approximated* (brought together). The inflammatory reaction may be greater than in primary healing. This results in more debris, cells, and exudate. The debris may have to be cleaned away *(debrided)* before healing can take place.

The process of healing by secondary intention is essentially the same as healing by primary intention. The major differences are the greater defect and the gaping wound edges. Healing and granulation take place from the edges inward and from the bottom of the wound upward until the defect is filled. There is more granulation tissue, and the result is a much larger scar.

Tertiary Intention. *Tertiary intention* (delayed primary intention) healing occurs with delayed suturing of a wound in which two layers of granulation tissue are sutured together. This occurs when a contaminated wound is left open and sutured closed after the infection is controlled. It also occurs when a primary wound becomes infected, is opened, is allowed to granulate, and is then sutured. Tertiary intention usually results in a larger and deeper scar than primary or secondary intention.

Wound Classification

Identifying the etiology of a wound is essential to classifying the wound properly. Wounds can be classified by their cause (surgical or nonsurgical; acute or chronic) or depth of tissue affected (superficial, partial thickness, or full thickness). A *superficial wound* involves only the epidermis. *Partial-thickness* wounds extend into the dermis. *Full-thickness* wounds have the deepest layer of tissue destruction because they involve the subcutaneous tissue and sometimes even extend into the fascia and underlying structures such as the muscle, tendon, or bone (see Fig. 25-3). (Wound classification systems are described in eTables 12-1 and 12-2, available on the website for this chapter.)

Another system used to classify open wounds is based on the color of the wound (red, yellow, black) rather than on the depth of tissue destruction (Table 12-7). The red-yellow-black classification can be applied to any wound allowed to heal by secondary intention, including surgically induced wounds left to heal without skin closure because of a risk for infection. A wound may have two or three colors at the same time. In this situation the wound is classified according to the least-desirable color present.

Complications of Healing

The shape and location of the wound determine how well the wound will heal. Certain factors can interfere with wound healing and lead to complications (Table 12-8 on p. 180).

NURSING AND COLLABORATIVE MANAGEMENT WOUND HEALING

NURSING ASSESSMENT

Observe and record the characteristics of the wound. Thoroughly assess the wound on admission (or first clinic visit) and on a regular basis thereafter. Deterioration in the wound will require you to assess and document changes more frequently. Various methods exist for measuring wounds. One method is presented in Fig. 12-9 on p. 181.

Record the consistency, color, and odor of any drainage and report if abnormal for the situation. *Staphylococcus* and *Pseudomonas* are common organisms that cause purulent, draining wounds.

TABLE 12-7 RED-YELLOW-BLACK CONCEPT OF WOUND CARE

Red Wound	Yellow Wound	Black Wound
		
Description and Characteristics		
Can be a superficial or deep wound if it is clean and pink in appearance, possible presence of serosanguineous drainage, pink to bright or dark red healing, or chronic wound with granulating tissue.	Presence of slough or soft necrotic tissue. Liquid to semiliquid slough with exudate ranging from creamy ivory to yellow-green.	Black, gray, or brown adherent necrotic tissue called eschar. Possible presence of purulent drainage. Risk of wound infection increases in proportion to amount of necrotic tissue present.
Examples		
Skin tears, pressure ulcers (stage II), partial-thickness or second-degree burns, and wounds created by trauma or surgery that are allowed to heal by secondary intention.	Wounds with nonviable necrotic tissue, which creates an ideal situation for bacterial growth and therefore must be removed.	Full-thickness or third-degree burns, pressure ulcers (stages III and IV), and gangrenous ulcers.
Purpose of Treatment		
Protection and gentle atraumatic cleansing.	Wound cleansing to remove nonviable tissue and absorb excess drainage.	Debridement of eschar and nonviable tissue.
Dressings and Therapy		
Transparent film dressing (e.g., Tegaderm, OpSite), hydrocolloid dressing (e.g., DuoDerm), hydrogels (e.g., Tegagel), gauze dressing with antimicrobial ointment or solution, Telfa dressing with antibiotic ointment.	Absorptive dressing, hydrocolloidal dressing, hydrogel covered with gauze, wound irrigations, hydrotherapy, moist gauze dressing with or without antibiotic or antimicrobial agent.	Topical debridement (enzyme, surgical, chemical) (see Table 12-11), hydrotherapy, moist gauze dressing, hydrogel covered with gauze, absorptive dressing covered with gauze.

In healthy people, wounds heal at a normal, predictable rate. Identify factors that may delay wound healing and contribute to chronic nonhealing wounds (Table 12-9, p. 181).

Chronic wounds are those that do not heal within the normal time (approximately 3 months). If a wound fails to heal in a timely manner, assess and identify factors that may delay healing. Refer the patient to a health care provider specializing in wound management. Time does not heal all wounds. While caring for patients during the healing process, you need to continually assess for complications (e.g., infection) associated with healing[2] (see Table 12-8).

NURSING IMPLEMENTATION

The type of wound management and dressings required depend on the type, extent, and characteristics of the wound and the phase of healing. The purposes of wound management include (1) cleaning a wound to remove any dirt and debris from the wound bed, (2) treating infection to prepare the wound for healing, and (3) protecting a clean wound from trauma so it can heal normally.

Superficial skin injuries may only need cleansing. Adhesive strips (e.g., Steri-Strips, butterflies), sutures (stitches), or tissue adhesives (fibrin sealants) are used to close wounds. Adhesive strips may be used instead of *sutures* in some injuries because they decrease *scarring* and are easier to care for. Sutures are used to close wounds because suture material provides the mechanical support necessary to sustain closure. A wide variety of suturing materials are available. In contrast, tissue adhesives are a biologic adhesive that can be used by themselves or in conjunction with sutures or tape.

If the wound is contaminated, it must be converted into a clean wound before healing can occur normally. Debridement of a wound that has multiple fragments or devitalized tissue may be necessary. If the source of inflammation is an internal organ (e.g., appendix, ruptured spleen), surgical removal of the organ is the treatment of choice.

For wounds that heal by primary intention, it is common to cover the incision with a dry, sterile dressing that is removed as soon as the drainage stops or in 2 to 3 days. Medicated sprays that form a transparent film on the skin may be used for dressings on a clean incision or injury. Transparent film dressings are also commonly used. Sometimes a surgeon will leave a surgical wound uncovered.

Sometimes drains are inserted into the wound to facilitate removal of fluid. The Jackson-Pratt drain is a suction drainage device consisting of a flexible plastic bulb connected to an internal plastic drainage tube (Fig. 12-10).

Topical antimicrobials and antibactericidals (e.g., povidone-iodine [Betadine], Dakin's solution [sodium hypochlorite],

TABLE 12-8 COMPLICATIONS OF WOUND HEALING

Adhesions
- Bands of scar tissue that form between or around organs.
- Adhesions may occur in the abdominal cavity or between the lungs and the pleura.
- Adhesions in abdomen may cause an intestinal obstruction.

Contractions
- Wound contraction is a normal part of healing.
- Complications occur when excessive contraction results in deformity.
- Shortening of muscle or scar tissue, especially over joints, results from excessive fibrous tissue formation (see Fig. 25-14).

Dehiscence
- Separation and disruption of previously joined wound edges (Fig. 12-5).
- Usually occurs when a primary healing site bursts open.
- May be caused by the following:
  - Infection causing an inflammatory process
  - Granulation tissue not strong enough to withstand forces imposed on wound
  - Obesity placing individuals at high risk for dehiscence because adipose tissue has less blood supply and may slow healing
  - Pocket of fluid (seroma, hematoma) developing between tissue layers and preventing the edges of the wound from coming together

Evisceration
- Occurs when wound edges separate to the extent that intestines protrude through wound.

Excess Granulation Tissue ("Proud Flesh")
- Excess granulation tissue may protrude above surface of healing wound.
- If the granulation tissue is cauterized or cut off, healing continues in normal manner.

Fistula Formation
- An abnormal passage between organs or a hollow organ and skin (abdominal or perianal fistula).

Infection (Fig. 12-6)
- ↑ Risk of infection when wound contains necrotic tissue or blood supply is ↓, patient's immune function is ↓ (e.g., from immunosuppressive drugs such as corticosteroids), undernutrition, multiple stressors, and hyperglycemia in diabetes.

Hemorrhage
- Bleeding is normal immediately after tissue injury and ceases with clot formation.
- Hemorrhage occurs as abnormal internal or external blood loss caused by suture failure, clotting abnormalities, dislodged clot, infection, or erosion of a blood vessel by a foreign object (tubing, drains) or infection process.

Hypertrophic Scars
- Inappropriately large, raised red and hard scars (Fig. 12-7).
- Occur when an overabundance of collagen is produced during healing.

Keloid Formation
- Great protrusion of scar tissue that extends beyond wound edges and may form tumor-like masses of scar tissue (Fig. 12-8).
- Permanent without any tendency to subside.
- Patients often complain of tenderness, pain, and hyperparesthesia, especially in early stages.
- Thought to be a hereditary condition occurring most often in dark-skinned people, particularly African Americans.

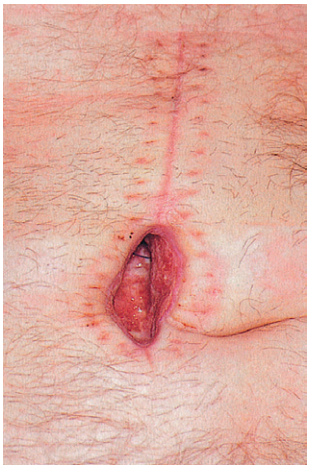

FIG. 12-5 Dehiscence following a cholecystectomy.

FIG. 12-6 Postoperative deep wound infection following wrist surgery.

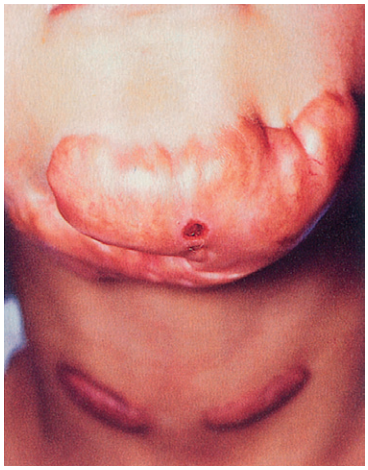

FIG. 12-7 Hypertrophic scarring.

FIG. 12-8 Keloid scarring.

hydrogen peroxide [H_2O_2], and chlorhexidine [Hibiclens]) should be used with caution in wound care because they can damage the new epithelium of healing tissue and delay healing. Therefore they should never be used in a clean granulating wound.

RED, YELLOW, AND BLACK WOUNDS. The management of wounds that heal by secondary intention depends on the cause of the injury and type of tissue in the wound. The red-yellow-black concept of wound care presented in Table 12-7 provides a method of dressing selection based on the wound tissue color. Examples of types of wound dressings are presented in Table 12-10, p. 182.

Red Wounds. In red wounds the purpose of treatment is protection of the wound and gentle cleansing (if indicated). Clean wounds that are granulating and re-epithelializing should be kept slightly moist and protected from further trauma until they

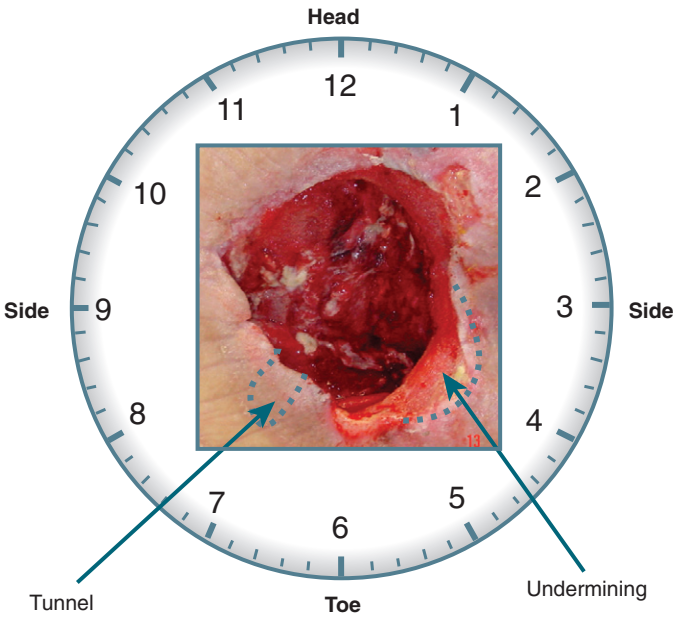

FIG. 12-9 Wound measurements are made in centimeters. The first measurement is oriented from head to toe, the second is from side to side, and the third is the depth (if any). If there is any tunneling (when cotton-tipped applicator is placed in wound, there is movement) or undermining (when cotton-tipped applicator is placed in wound, there is a "lip" around the wound), this is charted in respect to a clock, with 12 o'clock being toward the patient's head. This wound would be charted as a full-thickness, red wound, 7 × 5 × 3 cm, with a 3-cm tunnel at 7 o'clock and 2 cm undermining from 3 o'clock to 5 o'clock.

FIG. 12-10 Jackson-Pratt drainage device.

heal naturally. Do not let a wound dry out. Dryness is an enemy of wound healing. "Airing out" a wound is a great mistake. Wounds need a moist environment to heal.

A dressing material that keeps the wound surface clean and slightly moist is optimal to promote epithelialization. Transparent film or adhesive semipermeable dressings (e.g., OpSite, Tegaderm) are occlusive dressings that are permeable to oxygen. The wound is then usually covered with a sterile dressing. Unnecessary manipulation during dressing changes may destroy new granulation tissue and break down fibrin formation.

TABLE 12-9 FACTORS DELAYING WOUND HEALING

Factor	Effect on Wound Healing
Nutritional deficiencies	
• Vitamin C	Delays formation of collagen fibers and capillary development
• Protein	Decreases supply of amino acids for tissue repair
• Zinc	Impairs epithelialization
Inadequate blood supply	Decreases supply of nutrients to injured area, decreases removal of exudative debris, inhibits inflammatory response
Corticosteroid drugs	Impair phagocytosis by WBCs, inhibit fibroblast proliferation and function, depress formation of granulation tissue, inhibit wound contraction
Infection	Increases inflammatory response and tissue destruction
Smoking	Nicotine, a potent vasoconstrictor, impedes blood flow to healing areas
Mechanical friction on wound	Destroys granulation tissue, prevents apposition of wound edges
Advanced age	Slows collagen synthesis by fibroblasts, impairs circulation, requires longer time for epithelialization of skin, alters phagocytic and immune responses
Obesity	Decreases blood supply in fatty tissue
Diabetes mellitus	Decreases collagen synthesis, retards early capillary growth, impairs phagocytosis (result of hyperglycemia), reduces supply of O_2 and nutrients secondary to vascular disease
Poor general health	Causes generalized absence of factors necessary to promote wound healing
Anemia	Supplies less O_2 at tissue level

Yellow Wounds. A type of dressing used in yellow wounds is an absorption dressing that absorbs exudate and cleanses the wound surface. Absorption dressings work by drawing excess drainage from the wound surface. The amount of wound secretions determines the number of dressing changes.

Hydrocolloid dressings such as DuoDerm are also used to treat yellow wounds. The inner part of these dressings interacts with the exudate, forming a hydrated gel over the wound. When the dressing is removed, the gel separates and stays over the wound. The wound must be cleansed gently to prevent damage to newly formed tissue. These types of dressings are designed to be left in place for up to 7 days or until leakage occurs around the dressing.

Black Wounds. The immediate treatment is debridement of the nonviable, eschar tissue. The debridement method used depends on the amount of debris and the condition of the wound tissue (Table 12-11, p. 183).

NEGATIVE-PRESSURE WOUND THERAPY. Negative-pressure wound therapy *(vacuum-assisted wound closure)* is a type of therapy that uses suction to remove drainage and speed wound healing.[3] In this therapy the wound is cleaned, and a gauze or foam dressing is cut to the dimensions of the wound. A large occlusive dressing is applied, and a small hole is made over the gauze or foam dressing where the tubing is attached (Fig. 12-11, p. 183). The tubing is connected to a pump, which creates a negative pressure in the wound bed.

EVIDENCE-BASED PRACTICE

Translating Research Into Practice

What Is the Effect of Tap Water on Wound Cleansing?

Clinical Question

In patients with an infected wound (P), what is the effect of tap water (I) versus normal saline or no cleansing (C) on infection and healing rates (O)?

Best Available Evidence

Randomized controlled trials (RCTs) and quasi-randomized controlled trials

Critical Appraisal and Synthesis of Evidence

- Ten trials (n = 35 to 705/trial) with people who had acute infected wounds. Seven trials compared infection and healing rates with water versus normal saline. Three trials compared wound cleansing with various solutions versus no cleansing at all.
- No significant differences were found in infection rate and healing in wounds cleansed with tap water versus not cleansed at all.
- Tap water was more effective than saline in reducing wound infection rate.

Conclusion

- Using tap water to cleanse acute wounds does not increase infection rate and, in some cases, it may reduce infection.

Implications for Nursing Practice

- Carefully consider the option of using tap water when other wound cleansing solutions are not accessible.
- Evaluate water quality, type of wound, and the patient's overall health before using tap water.
- If potable tap water is not available, boiled water that is cooled or distilled water may be used in wound cleansing.

TABLE 12-10 TYPES OF WOUND DRESSINGS

Type	Description	Uses	Examples
Gauzes and nonwovens	Provide absorption of exudates. Support debridement if applied and kept moist.	Maintaining moist wound surface. Cleansing, packing, and covering a variety of wounds.	Numerous products available (e.g., Curity, Kling, Kerlix)
Nonadherent dressings	Woven or nonwoven dressings. May be impregnated with saline, petrolatum, or antimicrobials. Are minimally absorbent.	Minor wounds or as a second dressing.	Adaptic, Vaseline gauze, Xeroform
Semipermeable transparent films	Semipermeable membrane of polyurethane with acrylic adhesive. Transparency allows visualization of the wound. Minimally absorbent.	Dry, uninfected wounds or wounds with minimal drainage.	Bioclusive, Blisterfilm, OpSite, Polyskin, Suresite, Tegaderm, Transeal
Hydrocolloids	Gelatin, pectin, or carboxymethylcellulose bonded to a film or sheet. Produce a flat occlusive dressing that forms a gel on wound surface. Occlusion does not interfere with wound healing. Support debridement and prevent secondary infections.	Wounds with moderate to heavy drainage.	Aquacel, Combiderm, Comfeel, DuoDerm, Tegasorb
Foams	Sheets and other shapes of foamed polyurethane or silicone. Able to hold large amounts of exudate. Some come with adhesive backings; others require gauze wrapping.	Wounds with moderate to heavy drainage. Often used on new wounds.	Allevyn, Curafoam, Hydrasorb, Lyofoam, PolyMem
Hydrogels	Available in gels, gel-covered gauze, or sheets. Donate moisture to a dry wound and maintain a moist environment. Can rehydrate wound tissue. Debridement because of moisturizing effects. Require a secondary dressing.	Wounds with minimal drainage. Necrotic wounds.	Aquaform, Curasol, GranuGel, IntraSite, Nu-Gel, Purilon, Tegagel
Alginates	Derived from seaweed. Form a nonsticky gel on contact with draining wound. Easy to use over irregular-shaped wounds. Generally require a secondary dressing.	Wounds with moderate to heavy exudates (e.g., pressure ulcers, infected wounds).	AlgiSite, Algosteril, Kaltostat, Melgisorb, SeaSorb, Sorbsan
Antimicrobials	Wound covers that deliver agents such as silver and iodine, and polyhexamethylene biguanide (PHMB), which have antibacterial properties. Bacteria are not able to develop resistance to metals. Available as sponges, impregnated woven gauzes, film dressings, absorptive products, nylon fabric, nonadherent barriers, or a combination of materials.	Partial- and full-thickness wounds, over surgical incisions, or around tracheostomies.	Acticoat, Curity AMD, Iodoflex, Iodosorb, SilverDerm, Silverlon

For more information, see *http://search.woundsource.com*.

Although the exact mechanism for promoting healing is not known, it is thought that this therapy pulls excess fluid from the wound, reduces bacterial load, and encourages blood flow into the wound base. Monitor the patient's serum protein levels and fluid and electrolyte balance because of losses from the wound. Additionally, monitor the patient's coagulation studies (platelet count, prothrombin time [PT], partial thromboplastin time [PTT]).

HYPERBARIC OXYGEN THERAPY. Hyperbaric O_2 therapy (HBOT) is the delivery of O_2 at increased atmospheric pressures. It can be given systemically with the patient placed in an enclosed chamber where 100% O_2 is administered at 1.5 to 3 times the normal atmospheric pressure. HBOT allows O_2 to diffuse into the serum, rather than RBCs, and be transported to the tissues. By increasing the O_2 content in the serum, HBOT moves the O_2 past narrowed arteries and capillaries where RBCs cannot go.[4]

In addition, elevated O_2 levels stimulate *angiogenesis* (the production of new blood vessels), kill anaerobic bacteria, and increase the killing power of WBCs and certain antibiotics (e.g.,

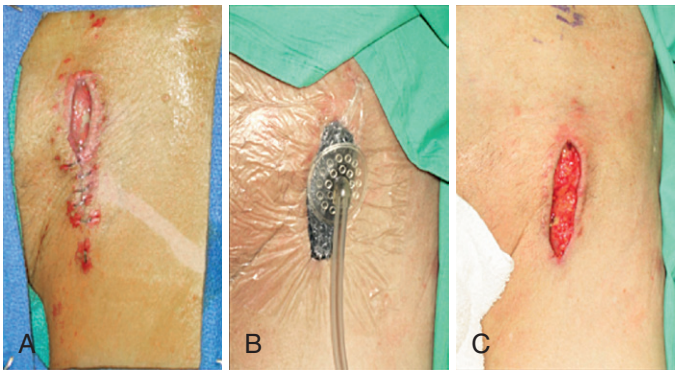

FIG. 12-11 Negative-pressure wound therapy. **A,** Femoral wound that is not healing. **B,** Negative-pressure wound therapy in place. **C,** Granulation tissue formation after therapy.

DELEGATION DECISIONS

Wound Care

In general, wound care for complex or nonhealing wounds should be managed by the registered nurse (RN). State nurse practice acts vary in the wound care actions allowed by licensed practical/vocational nurses (LPN/LVNs) and unlicensed assistive personnel (UAP).

Role of Registered Nurse (RN)

- Assess patients for pressure ulcer risk and develop a plan of care to prevent the development of pressure ulcers.
- Assess patients for factors that might delay wound healing and develop a plan of care to address these factors.
- Assess and document initial wound appearance, including wound size, depth, color, and drainage.
- Plan nursing actions to assist with wound healing, including wound care, positioning, and nutritional interventions.
- Choose dressings and therapies for wound treatment (in conjunction with the health care provider and/or wound care specialist).
- Implement wound care for complex or new wounds, including negative-pressure wound therapy and hyperbaric O_2 therapy.
- Evaluate whether wound care is effective in promoting wound healing.
- Provide teaching to patient and caregivers about home wound care and pressure ulcer prevention.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Perform sterile dressing changes on acute and chronic wounds.
- Apply ordered topical antimicrobials and antibactericidals to wounds.
- Apply prescribed dressings or medications for wound debridement.
- Collect and record data about wound appearance.
- Reinforce teaching that was provided by the RN.

Role of Unlicensed Assistive Personnel (UAP)

- Perform dressing changes for chronic wounds using clean technique (need to consider state nurse practice act and agency policy).
- Empty wound drainage containers and document drainage on intake and output record.
- Report changes in wound appearance or drainage to RN.

fluoroquinolones, aminoglycosides). HBOT accelerates granulation tissue formation and wound healing.

An alternative approach is to topically administer hyperbaric O_2 by creating a chamber around the injured limb. Most systemic treatments last from 90 to 120 minutes, and the number of treatments may vary from 10 to 60 depending on the condition being treated. The topical treatments can last 20 minutes twice daily or 4 to 6 hours daily. The number of treatments is highly variable.

TABLE 12-11 TYPES OF DEBRIDEMENT

Type	Description
Surgical debridement	• Quick method of debridement to prevent, control, or remove infection. • Used when large amounts of nonviable tissue are present. • Prepares wound bed for healing, skin grafting, or flaps.
Mechanical debridement	• Three methods: • *Wet-to-dry dressings* in which open-mesh gauze is moistened with normal saline, packed on or into wound surface, and allowed to dry. Wound debris adheres to dressing and then dressing is removed. • *Wound irrigation.* Make certain bacteria are not accidentally driven into wound with high irrigation pressure. • *Whirlpool.* Should not be used in a clean granulating wound. Used when minimal debris is present. Nonselective and will also debride some healthy tissue.
Autolytic debridement	• Semiocclusive or occlusive dressings (see Table 12-10) used to soften dry eschar by autolysis. • Assess area around wound for maceration when using these dressings. • Malodorous.
Enzymatic debridement	• Drugs applied topically to dissolve necrotic tissue and then covered with moist dressing (e.g., saline-moistened gauze). • Examples of these drugs include collagenase and papain and urea (e.g., Panafil, Gladase). • Process can be slow, and thick eschar may need to be scored with scalpel.

DRUG THERAPY. Platelet-derived growth factor is released from the platelets and stimulates cell proliferation and migration. Becaplermin (Regranex), a recombinant human platelet–derived growth factor gel, actively stimulates wound healing. This product should be used only when the wound is free of devitalized tissue and infection. It should not be used if cancer is suspected in the wound.

NUTRITIONAL THERAPY. Special nutritional measures facilitate wound healing. A high fluid intake is needed to replace fluid loss from perspiration and exudate formation. An increased metabolic rate intensifies water loss. Individuals at risk for wound healing problems are those with malabsorption problems (e.g., Crohn's disease, gastrointestinal [GI] surgery, liver disease), deficient intake or high energy demands (e.g., malignancy, major trauma or surgery, sepsis, fever), and diabetes.

Undernutrition puts a person at risk for poor healing. A diet high in protein, carbohydrate, and vitamins with moderate fat intake is necessary to promote healing. Protein is needed to correct the negative nitrogen balance resulting from the increased metabolic rate. Protein is also necessary for synthesis of immune factors, leukocytes, fibroblasts, and collagen, which are the building blocks for healing. Carbohydrate is needed for the increased metabolic energy required in inflammation and healing. If there is a carbohydrate deficit, the body will break down protein for the needed energy. Fats are also a necessary component in the diet to help in the synthesis of fatty acids and triglycerides, which are part of the cellular membrane.

Vitamin C is needed for capillary synthesis and collagen production by fibroblasts. The B-complex vitamins are necessary as coenzymes for many metabolic reactions. If a vitamin B

deficiency develops, a disruption of protein, fat, and carbohydrate metabolism will occur. Vitamin A is also needed in healing because it aids in the process of epithelialization. It increases collagen synthesis and tensile strength of the healing wound.

If the patient is unable to eat, enteral feedings and supplements should be the first choice if the GI tract is functional. Parenteral nutrition is indicated when enteral feedings are contraindicated or not tolerated. (Enteral and parenteral nutrition is discussed in Chapter 40.)

INFECTION PREVENTION AND CONTROL. You and the patient must scrupulously follow aseptic procedures for keeping the wound free from infection. Do not allow the patient to touch a recently injured area. The patient's environment should be as free as possible from contamination from items introduced by roommates and visitors. Antibiotics may be administered prophylactically to some patients.

If an infection develops, a culture and sensitivity test should be done to determine the organism and the most effective antibiotic for that specific organism. The culture should be taken before the first dose of antibiotic is given. Cultures can be obtained by needle aspiration, tissue culture, or swab technique. Physicians will obtain needle and tissue punch biopsy samples. As a nurse, you can obtain cultures using the swab technique.

Concurrent swab specimens are obtained from wounds using (1) wound exudates, (2) Z-technique, and (3) Levine's technique. The first technique samples visible wound exudates from the wound bed before cleansing. The Z-technique involves rotating a culture swab over the cleansed wound bed surface in a 10-point Z-track fashion. Levine's technique involves rotating a culture swab over a cleansed 1-cm^2 area near the center of the wound using sufficient pressure to extract wound fluid from deep tissue layers. Finally, a specimen of viable wound tissue is removed from the center of the wound using sterile technique. When collecting samples, do not take the specimen from exudate or eschar and do not use cotton-tipped swabs.

PSYCHOLOGIC IMPLICATIONS. The patient may be distressed at the thought or sight of an incision or wound because of fear of scarring or disfigurement. Drainage and odor from a wound often cause increased alarm. The patient needs to understand the healing process and the normal changes that occur as the wound heals. When changing a dressing, avoid inappropriate facial expressions that might alert the patient to problems with the wound or raise doubts about your ability to care for it. Wrinkling your nose may convey disgust to the patient. Be careful not to focus on the wound to the extent that the patient is not treated as a total person.

PATIENT TEACHING. Because patients are being discharged earlier after surgery and many have surgery as outpatients, it is important that the patient, the family, or both know how to care for the wound and perform dressing changes. Wound healing may not be complete for 4 to 6 weeks or longer. Adequate rest and good nutrition should be continued throughout this time. Physical and emotional stress should be minimal. Observing the wound for complications such as contractures, adhesions, and secondary infection is important. The patient should understand the signs and symptoms of infection. The patient should note changes in wound color and the amount of drainage. Teach the patient to notify the health care provider of any signs of abnormal wound healing.

Drugs are often taken for a time after recovery from the acute infection. Review drug-specific side effects and adverse effects with the patient, as well as methods to prevent side effects (e.g., taking with food or not). Teach the patient to contact the health care provider if any of these effects occur. Inform the patient of the need to continue the drugs for the specified time. For example, a patient who is instructed to take an antibiotic for 10 days may stop taking the drug after 5 days because of decreased or absent symptoms. However, the organism may not be entirely eliminated, and it may also become resistant to the antibiotic if the drug is not continued.

PRESSURE ULCERS

Etiology and Pathophysiology

A **pressure ulcer** is localized injury to the skin and/or underlying tissue (usually over a bony prominence) as a result of pressure or pressure in combination with shear and/or friction.

Pressure ulcers generally fall under the category of healing by secondary intention. The most common site for pressure ulcers is the sacrum, with heels being second. Factors that influence the development of pressure ulcers include the amount of pressure (intensity), the length of time the pressure is exerted on the skin (duration), and the ability of the patient's tissue to tolerate the externally applied pressure. Besides pressure, other factors that contribute to pressure ulcer formation include **shearing force** (pressure exerted on the skin when it adheres to the bed and the skin layers slide in the direction of body movement [e.g., when pulling patient up in bed]), *friction* (two surfaces rubbing against each other), and *excessive moisture*.

Factors that put a patient at risk for the development of pressure ulcers are presented in Table 12-12. Individuals at risk include those who are older, incontinent, bed- or wheelchair-bound, or recovering from spinal cord injuries.

Clinical Manifestations

The clinical manifestations of pressure ulcers depend on the extent of the tissue involved. Pressure ulcers are graded or staged according to their deepest level of tissue damage. Table 12-13 illustrates the pressure ulcer stages based on the National Pressure Ulcer Advisory Panel (NPUAP) guidelines. A pressure ulcer may be unstageable (see Table 12-13).

If the pressure ulcer becomes infected, the patient may display signs of infection (e.g., leukocytosis, fever). In addition, the pressure ulcer may increase in size, odor, and drainage; have necrotic tissue; and be indurated, warm, and painful. Untreated ulcers may lead to cellulitis, chronic infection, sepsis, and possibly death. The most common complication of a pressure ulcer is recurrence. Therefore it is important to note the location of previously healed pressure ulcers on a patient's initial admission assessment.

TABLE 12-12 RISK FACTORS FOR PRESSURE ULCERS

- Advanced age
- Anemia
- Contractures
- Diabetes mellitus
- Elevated body temperature
- Immobility
- Impaired circulation
- Incontinence
- Low diastolic blood pressure (<60 mm Hg)
- Mental deterioration
- Neurologic disorders
- Obesity
- Pain
- Prolonged surgery
- Vascular disease

NURSING AND COLLABORATIVE MANAGEMENT
PRESSURE ULCERS

In 1859 Florence Nightingale wrote, "If he has a bedsore, it's generally not the fault of the disease, but of the nursing."[5] Her comment emphasizes the critical role that nurses have in prevention and treatment of pressure ulcers.

Nursing and collaborative management are discussed together because the activities are interrelated. In addition to the nurse, other members of the health team, such as the wound care specialist, plastic surgeon, dietitian, physical therapist, and occupational therapist, can provide valuable input into the complex treatment necessary to prevent and treat pressure ulcers.

TABLE 12-13 STAGING OF PRESSURE ULCERS

Suspected Deep Tissue Injury

Purple or maroon localized area of discolored intact skin or blood-filled blister caused by damage of underlying soft tissue from pressure and/or shear. The area may be painful, firm, mushy, boggy, warmer, or cooler compared with adjacent tissue.

Stage I

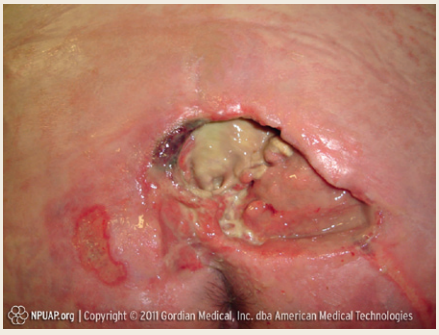
Intact skin with nonblanchable redness of a localized area, usually over a bony prominence. Darkly pigmented skin may not have visible blanching. Its color may differ from the surrounding area.

Stage II

Partial-thickness loss of dermis manifesting as a shallow open ulcer with a red-pink wound bed, without slough. May also manifest as an intact or open/ruptured serum-filled blister.

Stage III

Full-thickness tissue loss. Subcutaneous fat may be visible, but bone, tendon, and muscle are not exposed. Slough may be present but does not obscure the depth of tissue loss. May include undermining and tunneling.



Stage IV

Full-thickness tissue loss with exposed bone, tendon, or muscle. Slough or eschar may be present on some parts of the wound bed. Often includes undermining and tunneling.

Unstageable Ulcer

Full-thickness tissue loss in which the base of the ulcer is covered by slough (yellow, tan, gray, green, or brown) and/or eschar (tan, brown, or black) in the wound bed.

The true depth and stage of the ulcer cannot be determined until enough slough and eschar are removed. Stable (dry, adherent, intact without erythema or fluctuance) eschar on the heels provides a natural biologic cover and should not be removed.

Photos used with permission of the National Pressure Ulcer Advisory Panel.

NURSING ASSESSMENT

Assess patients for pressure ulcer risk initially on admission and at periodic intervals based on the patient's condition.

SAFETY ALERT

- In acute care, reassess patients for pressure ulcers every 24 hours.
- In long-term care, reassess residents weekly for the first 4 weeks after admission and then at least monthly or quarterly.
- In home care, reassess patients at every nurse visit.

Risk assessment should be done using a validated assessment tool such as the Braden Scale (available at *www.bradenscale.com* or in eTable 12-3 on the website for this chapter). Knowing the level of risk can help determine how aggressive preventive measures should be.

Conduct a thorough head-to-toe assessment on admission to identify and document a pressure ulcer. Thereafter conduct periodic reassessment of the skin and wounds. Identification of skin changes may be difficult in patients with dark skin. Table 12-14 presents techniques to help assess darker skin.

Subjective and objective data that should be obtained from a person with or at risk for a pressure ulcer are presented in Table 12-15.

NURSING DIAGNOSES

Nursing diagnoses for the patient with a pressure ulcer may include, but are not limited to, the following:

- Impaired skin integrity *related to* mechanical factors and physical immobilization
- Impaired tissue integrity *related to* impaired circulation and imbalanced nutritional state

PLANNING

The overall goals are that the patient with a pressure ulcer will (1) have no deterioration of the ulcer, (2) reduce or eliminate the factors that lead to pressure ulcers, (3) not develop an infection in the pressure ulcer, (4) have healing of pressure ulcers, and (5) have no recurrence.

NURSING IMPLEMENTATION

HEALTH PROMOTION. A primary nursing responsibility is the identification of patients at risk for developing pressure ulcers (see Tables 12-12 and 12-15) and implementation of pressure ulcer prevention strategies for those who are at risk. Prevention remains the best treatment for pressure ulcers.[6,7]

SAFETY ALERT

- Reposition patients frequently to prevent pressure ulcers (usually every 2 hours).
- Use devices to reduce pressure and shearing force (e.g., low-air-loss mattresses, foam mattresses, wheelchair cushions, padded commode seats, boots [foam, air], lift sheets) as appropriate.
- These devices do not replace the need for frequent repositioning.

ACUTE INTERVENTION. Care of a patient with a pressure ulcer requires local care of the wound and support measures of the whole person, such as adequate nutrition, pain management, control of other medical conditions, and pressure relief. Both conservative and surgical strategies are used in the treatment of pressure ulcers, depending on the stage and condition of the ulcer.

Once a pressure ulcer has developed, initiate interventions based on the ulcer characteristics (e.g., stage, size, location, amount of exudate, type of wound, presence of infection or pain) and the patient's general status (e.g., nutritional state, age, cardiovascular status, level of mobility). Carefully document the size of the pressure ulcer. A wound-measuring card or tape can be used to note the ulcer's maximum length and width in centimeters. To find the depth of the ulcer, take a sterile cotton-tipped applicator and soak it with saline. Gently place it into the deepest part of the ulcer, and then measure the length of the portion of the applicator that probed the ulcer. Documentation of the healing wound can be done using several available pressure ulcer healing tools such as the NPUAP Pressure Ulcer Scale for Healing (PUSH) tool[8] (eTable 12-4; available at *www.npuap.org/PDF/push3.pdf*).

Some agencies require that pictures of the pressure ulcer be taken initially and at regular intervals during the course of treatment. The informatics box on p. 187 has suggestions for digital imaging.

TABLE 12-14 ASSESSING PATIENTS WITH DARK SKIN

- Look for changes in skin color, such as skin that is darker (purplish, brownish, bluish) than surrounding skin.
- Use natural or halogen light source to accurately assess the skin color. Fluorescent light casts blue color, which can make skin assessment difficult.
- Assess the area for the skin temperature using your hand. The area may feel initially warm, then cooler.
- Touch the skin to feel its consistency. Boggy or edematous feel may indicate a stage I pressure ulcer.
- Ask the patient if he or she has any pain or itchy sensation.

TABLE 12-15 NURSING ASSESSMENT

Pressure Ulcers

Subjective Data

Important Health Information

Past health history: Stroke, spinal cord injury; prolonged bed rest or immobility; circulatory impairment; poor nutrition; altered level of consciousness; prior history of pressure ulcer; immunologic abnormalities; advanced age; diabetes; anemia; trauma

Medications: Use of opioids, hypnotics, systemic corticosteroids

Surgery or other treatments: Recent surgery

Functional Health Patterns

Nutritional-metabolic: Obesity, emaciation; decreased fluid, calorie, or protein intake; vitamin or mineral deficiencies; clinically significant malnutrition as indicated by low serum albumin, decreased total lymphocyte count, and decreased body weight (15% less than ideal body weight)

Elimination: Incontinence of urine, feces, or both

Activity-exercise: Weakness, debilitation, inability to turn and position body; contractures

Cognitive-perceptual: Pain or altered cutaneous sensation in pressure ulcer area; decreased awareness of pressure on body areas; capacity to follow treatment plan

Objective Data

General

Fever

Integumentary

Diaphoresis, edema, and discoloration, especially over bony areas such as sacrum, hips, elbows, heels, knees, ankles, shoulders, and ear rims, progressing to increased tissue damage characteristic of ulcer stages*

Possible Diagnostic Findings

Leukocytosis, positive cultures for microorganisms from pressure ulcer

*See Table 12-13.

EVIDENCE-BASED PRACTICE

Applying the Evidence

You are caring for S.W., an obese 86-year-old woman with a history of diabetes, hypertension, and chronic kidney disease. S.W. spends most of her time in bed or a wheelchair and now has a stage I pressure ulcer on her sacral area. You are doing discharge teaching with her daughter, who is her primary caregiver. You explain the importance of preventing further skin breakdown and that she needs to reposition her mother every 2 to 3 hours during the night. S.W.'s daughter tells you that she will reposition her mother during the night if her mother wakes up to use the commode. Otherwise, she needs her sleep because she watches her two young grandchildren during the day.

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
Repositioning remains the primary method of reducing risk for pressure ulcers. Pressure-reducing devices (e.g., foam mattress, padded commode seats) can also be used but should not be a substitute for repositioning.	You know that patients with pressure ulcers should be repositioned at least every 2 hours while in bed and every hour when in a chair. You also know that stage I pressure ulcers can rapidly deteriorate to stage II if proper care is not taken.	S.W.'s caregiver expresses the need to have a certain amount of uninterrupted sleep to maintain multiple family responsibilities. States she will reposition her mother at least every 2 hours while she is in bed during the day and every hour when she is in a wheelchair. S.W.'s caregiver states she will purchase a foam mattress, wheelchair cushion, and padded commode seat to help prevent further skin issues.

Your Decision and Action

You discuss the importance of repositioning as the primary method to prevent pressure ulcers and decrease the progression of existing pressure ulcers to more serious ones. S.W.'s daughter reiterates that she will not reposition her mother every 2 hours during the night. You can understand her decision and document this discussion in the patient's discharge teaching record.

INFORMATICS IN PRACTICE

Digital Images

To monitor wound progress, use digital photography. For the best images:

- Include a ruler with date, length, width, and depth of the wound in each photo.
- Position the patient the same way for each photo.
- Take the photo from the same angle each time. Pointing perpendicularly at the wound is best.
- Use natural light, without flash, whenever possible.
- Show the wound on a solid background, avoiding shiny underpads.

TABLE 12-16 PATIENT & CAREGIVER TEACHING GUIDE

Pressure Ulcer

When teaching the patient and caregiver to prevent and care for pressure ulcers do the following.

1. Identify and explain risk factors and etiology of pressure ulcers to patient and caregiver.
2. Assess all at-risk patients at time of first hospital and/or home visit or whenever the patient's condition changes. Thereafter assess at regular intervals based on care setting (every 24 hours for acute care or every visit in home care).
3. Teach the caregiver techniques for incontinence. If incontinence occurs, cleanse skin at time of soiling and use absorbent pads or briefs.
4. Demonstrate correct positioning to decrease risk of skin breakdown. Instruct caregiver to reposition a bed-bound patient at least every 2 hours, a chair-bound patient every hour. NEVER position the patient directly on the pressure ulcer.
5. Assess resources (i.e., caregiver's availability and skill, finances, equipment) of patients requiring pressure ulcer care at home. When selecting ulcer care dressing, consider cost and amount of caregiver time required.
6. Teach patient and/or caregiver to place clean dressings over sterile dressings using "no touch" technique when changing dressings. Instruct caregiver on disposal of contaminated dressings.
7. Teach patient and caregiver to inspect skin daily. Tell them to report any significant changes to the health care provider.
8. Teach patient and caregiver the importance of good nutrition to enhance ulcer healing.
9. Evaluate program effectiveness.

Local care of the pressure ulcer may involve debridement, wound cleaning, application of a dressing, and relief of pressure. It is important to select the appropriate pressure-relieving technique (e.g., pad, overlay, mattress, specialty bed) to relieve pressure and keep the patient off of the pressure ulcer. Whenever possible, do not turn the patient onto a body surface that is still reddened. Massage is contraindicated in the presence of acute inflammation and where there is the possibility of damaged blood vessels or fragile skin.[7]

Sliding down in bed causes friction and sheer. Encourage patients to reposition themselves by lifting rather than sliding and to use a trapeze if indicated. Lift sheets may be used to move patients up in bed or to transfer them.[9]

A pressure ulcer that has necrotic tissue or eschar (except for dry, stable necrotic feet or heels) must have the tissue removed by surgical, mechanical, enzymatic, or autolytic debridement methods. Once the pressure ulcer has been successfully debrided and has a clean granulating base, the goal is to provide an appropriate wound environment that supports moist wound healing and prevents disruption of the newly formed granulation tissue. Reconstruction of the pressure ulcer site by operative repair, including skin grafting, skin flaps, musculocutaneous flaps, or free flaps, may be necessary.

Clean pressure ulcers with noncytotoxic solutions that do not kill or damage cells, especially fibroblasts. Solutions such as Dakin's solution (sodium hypochlorite solution), acetic acid, povidone-iodine, and hydrogen peroxide are cytotoxic and therefore should not be used to clean pressure ulcers. It is also important to use enough irrigation pressure to adequately clean the pressure ulcer (4 to 15 psi) without causing trauma or damage to the wound. To obtain this pressure, use a 30-mL syringe and a 19-gauge needle.

After the pressure ulcer has been cleansed, cover it with an appropriate dressing. The current trend is to keep a pressure ulcer slightly moist, rather than dry, to enhance re-epithelialization. Some factors to consider when selecting a dressing are maintenance of a moist environment, prevention

of the wound from drying out, ability to absorb the wound drainage, location of the wound, amount of caregiver time required to change the dressing, cost of the dressing, presence of infection, clean versus sterile dressings, and care delivery setting. A wet-to-dry dressing should never be used on a clean granulating pressure ulcer. This type of dressing should be used only for mechanical debridement of the wound. (Dressings are discussed in Table 12-10.)

Stages II through IV pressure ulcers are considered contaminated or colonized with bacteria. Remember that in people who have chronic wounds or are immunocompromised, the clinical signs of infection (purulent exudate, odor, erythema, warmth, tenderness, edema, pain, fever, and elevated WBC count) may not be present even though the pressure ulcer is infected.[10]

The maintenance of adequate nutrition is an important nursing responsibility for the patient with a pressure ulcer. Often, the patient is debilitated and has a poor appetite secondary to inactivity. Oral feedings must be adequate in calories, protein, fluids, vitamins, and minerals to meet the patient's nutritional requirements. The caloric intake needed to correct and maintain nutritional balance may be 30 to 35 calories/kg/day and 1.25 to 1.50 g of protein/kg/day.

Enteral feedings can be used to supplement the oral feedings. When oral and enteral feedings are inadequate, parenteral nutrition consisting of amino acid and glucose solutions is used. (Parenteral and enteral nutrition is discussed in Chapter 40.)

AMBULATORY AND HOME CARE. Pressure ulcers affect the quality of life of patients and their caregivers. Because pressure ulcers commonly recur, teaching prevention techniques to both the patient and the caregiver is extremely important (Table 12-16, p. 187). A sixth-grade-level version of the patient guide to pressure ulcer prevention is available for use in patient teaching *(www.npuap.org/PU_Prev_Points.pdf)*. The caregiver needs to know the etiology of pressure ulcers, prevention techniques, early signs, nutritional support, and care techniques for actual pressure ulcers. Because the patient with a pressure ulcer often requires extensive care for other health problems, it is important that the nurse support the caregiver with the added responsibility for pressure ulcer treatment. eNursing Care Plan 12-2 (available on the website for this chapter) outlines the care for the patient with a pressure ulcer.

EVALUATION

The expected outcomes are that the patient with a pressure ulcer will have

- Healing of pressure ulcer(s)
- Intact skin with no further breakdown

CASE STUDY

Inflammation and Infection

iStockphoto/Thinkstock

Patient Profile

G.N., a 58-year-old African American man, was admitted to the hospital emergency department with partial-thickness burns that involved his face, neck, and upper trunk. He also had a lacerated right leg. His injuries occurred about 36 hours earlier when he fell out of a tree onto his gas grill (which was lit) while trying to get his cat.

Subjective Data

- Complains of slightly hoarse voice and irritated throat
- States that he tried to treat himself because he does not have health insurance
- Has been coughing up sooty sputum
- Complains of severe pain in left hip

Objective Data

Physical Examination

- Leg wound is gaping and has drainage: temperature 101.1°F (38.4°C).
- X-rays reveal a fractured right tibia and fractured left hip.

Laboratory Studies

- WBC count 26,400/μL (26.4×10^9/L) with 80% neutrophils (10% bands)

Collaborative Care

- Surgery is performed to repair the left hip.

Discussion Questions

1. What clinical manifestations of inflammation did G.N. exhibit, and what are their pathophysiologic mechanisms?
2. What type of exudate formation did he develop?
3. What is the basis for the development of the temperature?
4. What is the significance of his WBC count and differential?
5. Because his wound was deep, primary tissue healing was not possible. How would you expect healing to take place? What complications could he develop?
6. What risk factors does G.N. have to develop a pressure ulcer?
7. ***Priority Decision:*** Based on the assessment data provided, what are the priority nursing diagnoses? Are there any collaborative problems?
8. ***Delegation Decision:*** What nursing activities related to wound care can be delegated to unlicensed assistive personnel (UAP)?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient 1 day postoperative after abdominal surgery has incisional pain, 99.5°F temperature, slight erythema at the incision margins, and 30 mL serosanguineous drainage in the Jackson-Pratt drain. Based on this assessment, what conclusion would the nurse make?
   - **a.** The abdominal incision shows signs of an infection.
   - **b.** The patient is having a normal inflammatory response.
   - **c.** The abdominal incision shows signs of impending dehiscence.
   - **d.** The patient's physician needs to be notified about her condition.
2. The nurse assessing a patient with a chronic leg wound finds local signs of erythema and pain at the wound site. What would the nurse anticipate being ordered to assess the patient's systemic response?
   - **a.** Serum protein analysis
   - **b.** WBC count and differential
   - **c.** Punch biopsy of center of wound
   - **d.** Culture and sensitivity of the wound

3. A patient in the unit has a 103.7° F temperature. Which intervention would be most effective in restoring normal body temperature?
   a. Use a cooling blanket while the patient is febrile.
   b. Administer antipyretics on an around-the-clock schedule.
   c. Provide increased fluids and have the UAP give sponge baths.
   d. Give prescribed antibiotics and provide warm blankets for comfort.
4. A nurse is caring for a patient who has a pressure ulcer that is treated with debridement, irrigations, and moist gauze dressings. How should the nurse anticipate healing to occur?
   a. Tertiary intention
   b. Secondary intention
   c. Regeneration of cells
   d. Remodeling of tissues
5. A nurse is caring for a patient with diabetes who is scheduled for amputation of his necrotic left great toe. The patient's WBC count is $15.0 \times 10^6/\mu L$, and he has coolness of the lower extremities, weighs 75 lb more than his ideal body weight, and smokes two packs of cigarettes per day. Which priority nursing diagnosis addresses the primary factor affecting the patient's ability to heal?
   a. Imbalanced nutrition: more than body requirements *related to* high-fat foods
   b. Impaired tissue integrity *related to* decreased blood flow secondary to diabetes and smoking
   c. Ineffective peripheral tissue perfusion *related to* narrowed blood vessels secondary to diabetes and smoking
   d. Ineffective individual coping *related to* indifference and denial of the long-term effects of diabetes and smoking
6. Which one of the orders should a nurse question in the plan of care for a patient with a stage III pressure ulcer?
   a. Pack the ulcer with foam dressing.
   b. Turn and position the patient every 2 hours.
   c. Clean the ulcer every shift with Dakin's solution.
   d. Assess for pain and medicate before dressing change.
7. An 85-year-old patient is assessed to have a score of 16 on the Braden Scale. Based on this information, how should the nurse plan for this patient's care?
   a. Implement a q2hr turning schedule with skin assessment.
   b. Place DuoDerm on the patient's sacrum to prevent breakdown.
   c. Elevate the head of bed to 90 degrees when the patient is supine.
   d. Continue with weekly skin assessments with no special precautions.
8. A 65-year-old stroke patient with limited mobility has a purple area of suspected deep tissue injury on the left greater trochanter. Which nursing diagnoses is/are most appropriate *(select all that apply)?*
   a. Acute pain *related to* tissue damage and inflammation
   b. Impaired skin integrity *related to* immobility and decreased sensation
   c. Impaired tissue integrity *related to* inadequate circulation secondary to pressure
   d. Risk for infection *related to* loss of tissue integrity and undernutrition secondary to stroke
9. An 82-year-old man is being cared for at home by his family. A pressure ulcer on his right buttock measures $1 \times 2 \times 0.8$ cm in depth, and pink subcutaneous tissue is completely visible on the wound bed. Which stage would the nurse document on the wound assessment form?
   a. Stage I
   b. Stage II
   c. Stage III
   d. Stage IV

1. b, 2. b, 3. b, 4. b, 5. b, 6. c, 7. a, 8. b, c, 9. c

LEARNING OUTCOMES

1. Differentiate the common terms related to genetics and genetic disorders: *autosomal, carrier, heterozygous, homozygous, mutation, recessive,* and *X-linked gene.*
2. Differentiate between the two common causes of genetic mutations.
3. Compare and contrast the three most common inheritance patterns of genetic disorders.
4. Describe the most common classifications of genetic disorders.
5. Explore the complex ethical and social implications of genetic testing.
6. Analyze the role of pharmacogenetics in developing personalized drug therapy.
7. Discuss your role in assisting the patient and family in dealing with genetic issues.

KEY TERMS

genetics, p. 190
genomics, p. 190
hereditary, Table 13-1, p. 191
heterozygous, Table 13-1, p. 191
homozygous, Table 13-1, p. 191
mutation, Table 13-1, p. 191
pharmacogenetics, p. 198
pharmacogenomics, p. 198

GENETICS AND GENOMICS

In the 1860s an Austrian monk named Gregor Mendel, while experimenting with pea plants, discovered how traits are transmitted from parents to offspring. This discovery laid the foundation for modern **genetics,** the study of genes and their role in inheritance. Genetics determines the way that certain traits or conditions are passed down from one generation to another. **Genomics** is the study of all of a person's genes (the *genome*), including interactions of these genes with each other and with the person's environment. (Common terms used in genetics and genomics are defined in Table 13-1.) Genomics includes the study of complex diseases such as heart disease, asthma, diabetes mellitus, and cancer because these diseases are typically caused by a combination of genetic and environmental factors rather than by a single gene.

A person's genes can have a profound impact on health and disease. More than 4000 diseases are thought to be related to altered genes. Genomic factors play a role in 9 of the 10 leading causes of death in the United States, including heart disease, cancer, diabetes, stroke, and Alzheimer's disease.[1]

Genomics may help us understand why some people who eat healthy diets and exercise regularly still die at a young age of cancer, whereas some people eat unhealthy diets and never exercise, and yet live to an old age.

The identification of a genetic basis for many human diseases has the potential to strongly influence the care of patients at risk for or diagnosed with a disease that has a genetic link. You need to know the basic principles of genetics, be familiar with the impact that genetics and genomics have on health and disease, and be prepared to assist the patient and family with genetic issues.

Basic Principles of Genetics

Genes. *Genes* are the basic units of heredity. There are approximately 20,000 to 25,000 genes in each person's genetic makeup, or *genome.* Genes encode (carry the instructions) for proteins that direct the activities of cells and functions of the

TABLE 13-1 GLOSSARY OF GENETIC AND GENOMIC TERMS

Term	Definition
Allele	An alternative form of a gene. Each person receives two alleles of a gene, one from each biologic parent. Different alleles produce variations in inherited traits such as eye color and blood type.
Autosome	Any chromosome that is not a sex chromosome. Humans have 22 pairs of autosomes.
Carrier	Individual who carries a copy of a mutated gene for a recessive disorder.
Chromosome	A compact structure containing DNA and proteins present in nearly all cells of the body. Normally each cell has 46 chromosomes in 23 pairs. Each biologic parent contributes one of each pair of chromosomes.
Codominance	Two dominant versions of a trait that are both expressed in the same individual.
Congenital disorder	Condition present at birth.
Dominant allele	Gene that is expressed in the phenotype of a heterozygous individual.
Familial disorder	Condition that affects more than one person in a family.
Gene	The basic unit of heredity information located on a specific part of a chromosome. Genes direct cells to make proteins and guide almost every aspect of operation and repair of cells.
Genetic risk factor	A change in a gene that increases a person's risk of developing a disease.
Genetics	Study of genes and their role in inheritance.
Genome	All the DNA contained in an individual.
Genome-wide association study (GWAS)	A study approach that involves scanning complete sets of DNA (genomes) of many individuals to find genetic variations associated with a particular disease.
Genomics	Study of how genes interact and influence people's biologic and physical characteristics.
Genotype	Genetic identity of an individual. This identity does not show as outward characteristics.
Hereditary	Transmission of a disease, condition, or trait from parent to children.
Heterozygous	Having two different alleles for one given gene, one inherited from each parent.
Homozygous	Having two identical alleles for one given gene, one inherited from each parent.
Locus	Position of a gene on a chromosome.
Mutation	A change in DNA or a gene. Sometimes these changes are passed from parent to children.
Oncogene	Gene that is able to initiate and contribute to the conversion of normal cells to cancer cells.
Pedigree	Family tree that contains the genetic characteristics and disorders of that particular family.
Pharmacogenetics	Study of variability of responses to drugs related to variations in single genes.
Pharmacogenomics	Study of variability of responses to drugs related to variations in and interactions of multiple genes.
Phenotype	Observable traits or characteristics of an individual (e.g., hair color).
Protooncogene	Normal cellular genes that are important regulators of normal cellular processes. Mutations can activate them to become oncogenes.
Recessive allele	Allele that has no noticeable effect on the phenotype in a heterozygous individual.
Trait	Physical characteristic that one inherits, such as hair or eye color.
X-linked gene	Gene located on the X chromosome. In general, sex-linked disorders are only seen in males.

body. Genes control how a cell functions, including how quickly it grows, how often it divides, and how long it lives. To control these functions, genes produce proteins that perform specific tasks and act as messengers for the cell. Therefore it is essential that each gene have the correct instructions or "code" for making its protein so that the protein can perform the proper function for the cell.[2]

Genes are arranged in a specific linear formation along a chromosome (Fig. 13-1). Each gene has a specific location on a chromosome, termed a *locus.* An *allele* is one of two or more alternative forms of a gene that occupy corresponding loci on *homologous chromosomes* (a pair of chromosomes having corresponding deoxyribonucleic acid [DNA] sequences, with one coming from the mother and the other from the father). Each allele codes for a specific inherited characteristic.

When there are two different alleles, the allele that is fully expressed is the *dominant allele.* The other allele that lacks the ability to express itself in the presence of a dominant allele is the *recessive allele.* Physical traits expressed by an individual are termed the *phenotype,* and the actual genetic makeup of the individual is termed the *genotype.*

Chromosomes. *Chromosomes* are contained in the nucleus of a cell and occur in pairs. Humans have 23 pairs of chromosomes; 22 of the 23 pairs of chromosomes are *homologous* and are termed *autosomes.* Autosomes are the same in both males and females. The sex chromosomes make up the twenty-third pair of chromosomes. A female has two X chromosomes, and a male has one X and one Y chromosome. One chromosome of each pair is inherited from the mother and one from the father. One half of each child's chromosomes (and therefore the genetic makeup) comes from his or her father and one half from his or her mother.

DNA. Genes are made up of a nucleic acid called *deoxyribonucleic acid* (DNA). DNA stores genetic information and encodes the instructions for synthesizing specific proteins needed to maintain life. DNA also dictates the rate at which proteins are made. Every somatic cell in a person's body has the same DNA.

The information in DNA is stored as a code made up of four nitrogenous bases: adenine (A), guanine (G), cytosine (C), and thymine (T). Human DNA consists of about 3 billion bases, and more than 99% of those bases are the same in all people. The

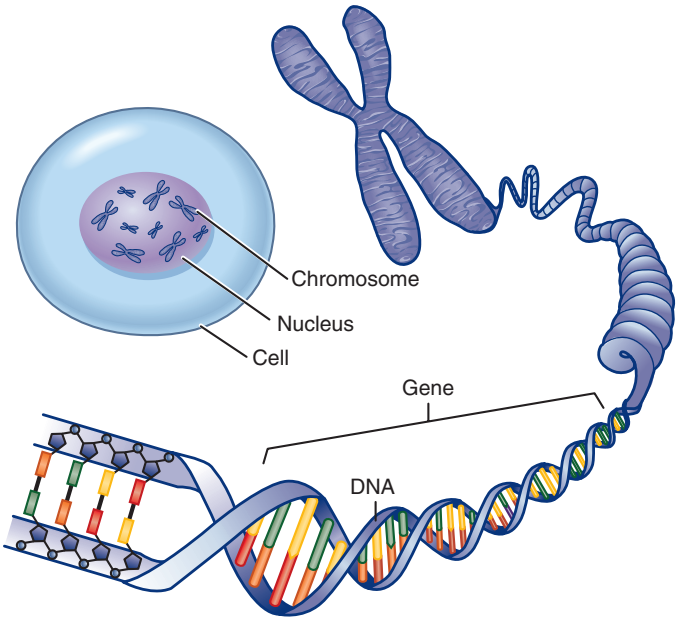

FIG. 13-1 The long, stringy DNA that makes up genes is spooled within chromosomes inside the nucleus of a cell. (Note that a gene would actually be a much longer stretch of DNA than what is shown here.)

order (or sequence) of these bases determines the information for building and maintaining an organism. This is similar to the way letters of the alphabet are used to create words and sentences.

DNA bases pair up with each other, A with T and C with G, to form units called *base pairs*. Each base is also attached to a sugar molecule and a phosphate molecule (Fig. 13-2). Together, a base, sugar, and phosphate are called a *nucleotide*. Nucleotides are arranged in two long strands that form a spiral called a *double helix*. The structure of the double helix is somewhat like a ladder, with the base pairs forming the ladder's rungs and the sugar and phosphate molecules forming the ladder's vertical sidepieces.

DNA can *replicate* (make copies of itself). Each strand of DNA in the double helix can serve as a pattern for duplicating the sequence of bases. When cells divide, each new cell needs to have an exact copy of the DNA that was in the parent (original) cell.

If the chromosomes in one of your cells were uncoiled and placed end-to-end, the DNA would be about 6 feet long. If all of the DNA in your body were connected, it would stretch about 67 billion miles.[3]

RNA. *Ribonucleic acid* (RNA) is similar to DNA, but with some significant differences. Like DNA, RNA contains the nitrogenous bases adenine, guanine, and cytosine. However, RNA lacks the nitrogenous base thymine and instead contains uracil. RNA is single stranded and contains ribose instead of deoxyribose sugar. RNA transfers the genetic information obtained from DNA to the proper location for protein synthesis.

Protein Synthesis. Protein synthesis, or the making of proteins, occurs in two steps: *transcription* and *translation*. (Transcription and translation are shown in eFig. 13-1 on the website for this chapter.) Transcription is the process by which messenger RNA (mRNA) is synthesized from single-stranded DNA. The mRNA becomes attached to a ribosome, where translation occurs. At this point another specialized type of RNA, transfer RNA (tRNA), arranges the amino acids in the correct sequence

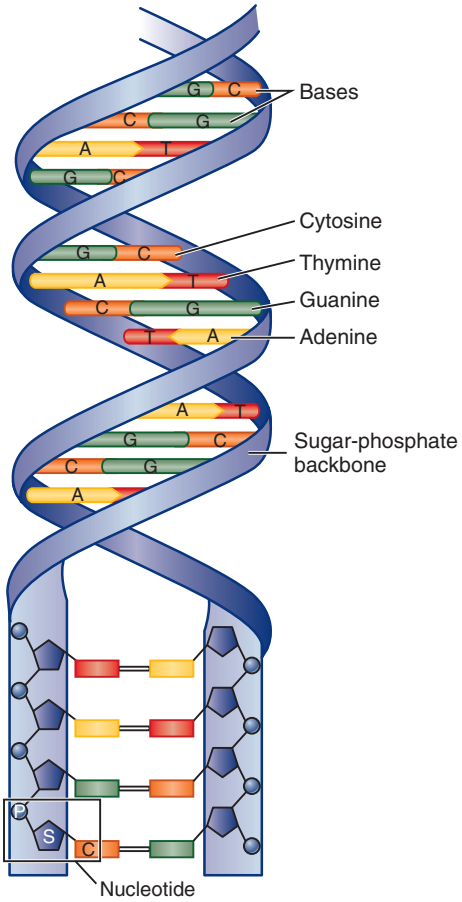

FIG. 13-2 DNA consists of two long, twisted chains made up of nucleotides. Each nucleotide contains one base, one phosphate molecule *(P)*, and the sugar molecule deoxyribose *(S)*. The bases in DNA nucleotides are adenine *(A)*, thymine *(T)*, cytosine *(C)*, and guanine *(G)*.

to assemble the protein. Once the protein is completed, it is released from the ribosome and is able to perform its specific function in the cell.

Mitosis. *Mitosis* is a type of cell division that results in the formation of genetically identical daughter cells. Before cell division the chromosomes duplicate, and each new cell (called daughter cells) receives an exact replica of the chromosomes from the original cell (called the parent cell).

Meiosis. *Meiosis* occurs only in sexual reproductive cells. In meiosis the number of chromosomes is reduced, resulting in half of the usual number of chromosomes. Therefore oocytes and sperm contain only a single copy of each chromosome, whereas all other body cells contain duplicates of each chromosome.

Genetic Mutations

A *mutation* is any change in the usual DNA sequence. Subtle variations in DNA are called *polymorphisms* (meaning *many forms*). Many of these *gene* polymorphisms account for slight variations among people such as hair and eye color. However, some gene variations may result in disease or an increased risk for disease. These gene variations or changes are referred to as *mutations*.

A genetic mutation is like a spelling error in a gene's sequence. For example, in people with sickle cell disease, a substitution of a single base (adenine is replaced by thymine) in a single gene

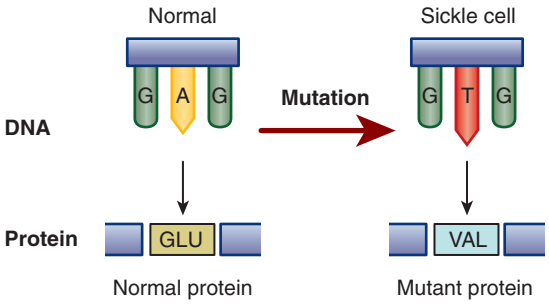

FIG. 13-3 In sickle cell disease a single gene mutation leads to mutant (incorrect) protein. The substitution of valine *(VAL)* for glutamic acid on the β-globin chain of hemoglobin produces abnormal hemoglobin, hemoglobin S (Hb S). In response to low O_2 levels, the erythrocytes with Hb S stiffen and elongate, taking on a sickle shape (see Fig. 31-3).

(β-globin gene) causes the disease (Fig. 13-3). Mutations range in size from a single DNA base (building block) to a large segment of a chromosome.

The change in gene structure may alter the type and/or amount of protein produced. The protein may not work at all, or it may work incorrectly. In some cases, genetic mutations do not have an obvious effect on the people who have them.

Types of Mutations. Genetic mutations occur in two ways. They can be inherited from a parent (germline mutation) or acquired (somatic mutation) during a person's lifetime.

Germline mutations are passed from parent to child. These mutations are present in the oocyte and sperm cells. This type of mutation is present throughout a person's life in virtually every cell in the body.

Acquired (somatic) mutations occur in the DNA of a cell at some time during a person's life. An acquired mutation is passed on to all cells that develop from that single cell. These mutations in somatic cells cannot be passed on to the next generation. Acquired mutations can occur if (1) a mistake is made as DNA replicates during cell division or (2) environmental factors alter the DNA.

Mutations can occur when a cell is dividing. Considering that 3 billion base pairs are replicated in each cell division, DNA replication is very accurate. However, during replication occasionally mistakes such as deletions, insertions, or duplication of DNA material can occur. Although DNA repair enzymes can correct replication errors, mistakes can go uncorrected.[4]

In addition to cell division, DNA damage can also occur from environmental factors. For example, ultraviolet (UV) radiation can cause DNA damage, leading to skin cancer. Toxins in cigarettes can lead to lung cancer. Many chemotherapy drugs used to treat cancer target the DNA of both cancer cells and healthy cells. In the process these drugs increase a person's risk of developing secondary cancers (see Chapter 16).

Cells have built-in mechanisms that catch and repair most of the changes that occur during DNA replication or from environmental damage. However, as we age, our DNA repair does not work as effectively and we accumulate changes in our DNA.

Inheritance Patterns

Genetic disorders can be categorized into autosomal dominant, autosomal recessive, or X-linked (sex-linked) recessive disorders (Table 13-2). If the mutant gene is located on an autosome, the genetic disorder is called *autosomal.* If the mutant gene is on the X chromosome, the genetic disorder is called *X-linked.*

TABLE 13-2 COMPARISON OF GENETIC DISORDERS

Characteristics	Examples
Autosomal Dominant	
Males and females are affected* equally. More common than recessive disorders and usually less severe. Affected individuals show variable expression. Affected individuals may have an affected parent. Children of a heterozygous (affected) parent have a 50% chance of being affected. Individuals are affected in successive generations.	Breast and ovarian cancer related to *BRCA* genes Familial hypercholesterolemia Hereditary nonpolyposis colorectal cancer Huntington's disease Neurofibromatosis Marfan's syndrome
Autosomal Recessive	
Males and females are affected equally. Heterozygotes are carriers and usually asymptomatic. Affected individuals may have unaffected† parents who are heterozygous for trait. Children of two heterozygous parents have 25% chance of being affected and 50% chance of being carriers (see Fig. 13-9). Frequently there is a no family history of disease.	Cystic fibrosis Phenylketonuria Sickle cell disease Tay-Sachs disease Thalassemia
X-Linked Recessive	
Most affected individuals have unaffected parents. Affected individuals are usually males. Daughters of affected male are carriers. Sons of affected male are unaffected (unless mother is a carrier).	Duchenne muscular dystrophy Hemophilia Wiskott-Aldrich syndrome

*Have the disease.
†Do not have the disease.

Family pedigrees for autosomal recessive and dominant disorders and X-linked recessive disorders are shown in Figs. 13-4 and 13-5.

Autosomal dominant disorders are caused by a mutation of a single gene pair (heterozygous) on a chromosome. A dominant allele prevails over a normal allele. Autosomal dominant disorders show variable expression. *Variable expression* means that the symptoms expressed by the individuals with the mutated gene vary from person to person even though they have the same mutated gene. Although autosomal dominant disorders have a high probability of occurring in families, sometimes these disorders cause a new mutation or skip a generation. This is termed *incomplete penetrance.*

Autosomal recessive disorders are caused by mutations of two gene pairs (homozygous) on a chromosome. A person who inherits one copy of the recessive allele does not develop the disease because the normal allele predominates. However, this person is a *carrier.*

X-linked recessive disorders are caused by a mutation on the X chromosome. Usually only men are affected by this disorder because women who carry the mutated gene on one X chromosome have another X chromosome to compensate for the mutation. However, women who carry the mutated gene can transmit it to their offspring. It is possible for women to have X-linked recessive disorders, and this can occur when an affected male mates with an unaffected female carrier. This points to the

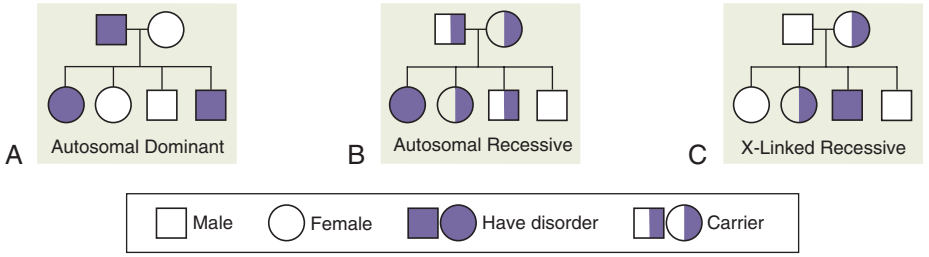

FIG. 13-4 Examples of family pedigrees showing inheritance of **(A)** autosomal dominant, **(B)** autosomal recessive, and **(C)** X-linked recessive disorders.

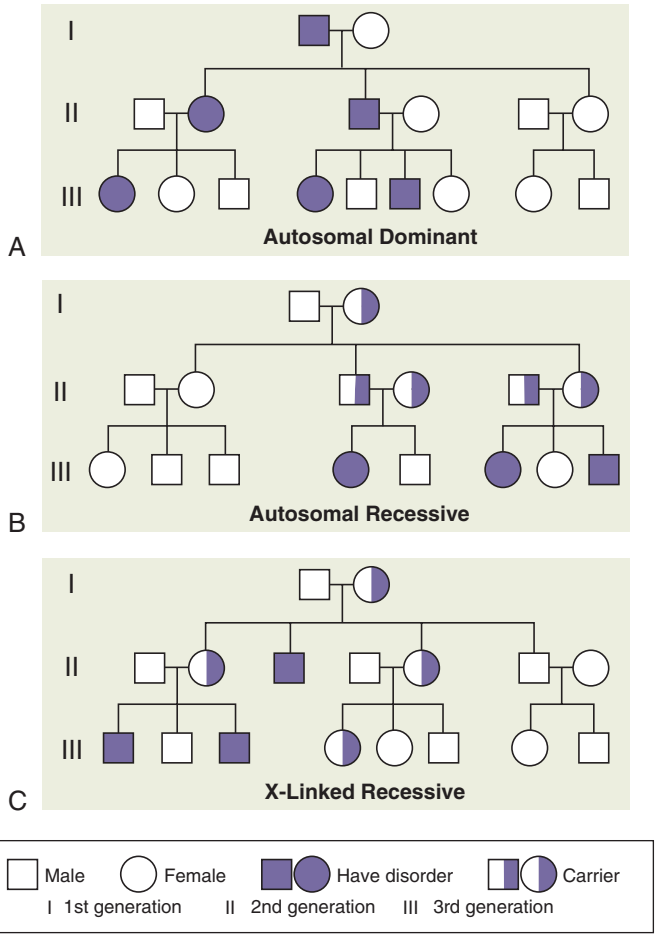

FIG. 13-5 Family pedigrees showing three generations. **A,** Family pedigree suggestive of an autosomal dominant disorder. **B,** Family pedigree suggestive of an autosomal recessive disorder. **C,** Family pedigree suggestive of an X-linked recessive disorder.

importance of testing the carrier status of the female partner of affected males. *X-linked dominant disorders* do exist but are rare.

Multifactorial inherited conditions are caused by a combination of genetic and environmental factors. These disorders run in families but do not show the same inherited characteristics as the single gene mutation conditions. Multifactorial conditions include diabetes mellitus, obesity, hypertension, cancer, and coronary artery disease.

Human Genome Project

The Human Genome Project (HGP), which was completed in 2003, mapped the entire human genome.[5] Analysis of the data will continue for many years. The knowledge gained through the HGP will (1) help improve the diagnosis of diseases, (2) allow for earlier detection of genetic predisposition to diseases, and (3) play a critical role in determining risk assessment for genetic-related diseases. In addition, the results of the HGP assist in matching organ donors with transplant recipients.

GENETIC DISORDERS

A *genetic disorder* is caused in whole or in part by an alteration in the DNA sequence. As discussed in the section on genetic mutations (pp. 192-193), genetic disorders can be inherited (person born with altered genetic code) or they can be acquired (e.g., replication errors, damage to DNA from toxins). Genetic disorders can be caused by (1) a mutation in one gene (single gene disorder); (2) mutations in multiple genes (multifactorial inheritance disorder), which are often related to environmental factors; or (3) damage to chromosomes (changes in the number or structure of entire chromosomes).

Classification of Genetic Disorders

Single Gene Disorders. Some genetic disorders result from a single gene mutation (Fig. 13-6, *A*). Examples of these diseases include cystic fibrosis, sickle cell disease, and polycystic kidney disease. The pattern of inheritance for single gene disorders can be autosomal dominant, autosomal recessive, or X-linked. Single gene disorders are relatively rare compared with more commonly occurring multifactorial genetic disorders such as diabetes mellitus and heart disease.

Multifactorial Genetic Disorders. Multifactorial genetic disorders are complex diseases that result from small inherited variations in genes, often acting together with environmental factors (Fig. 13-6, *B*). Heart disease, diabetes, and most cancers are examples of such disorders.

Although many common diseases are usually caused by inheritance of mutations in multiple genes, such diseases can also be caused by rare hereditary mutations in a single gene. In these cases, genetic mutations that cause or strongly predispose a person to these diseases run in a family. These mutations can significantly increase each family member's risk of developing the disease. One example is breast cancer, where inheritance of a mutated *BRCA1* or *BRCA2* gene confers significant risk of developing the disease.

Epigenetics. Environmental factors can alter the way our genes are expressed (i.e., which genes are "switched" on or off). Identical twins, who have the same genetic makeup, do not always develop the same diseases or at the same rate.[6]

Genetic and environmental factors interact to influence a person's predisposition to different diseases. *Epigenetics* is the study of changes in gene function that do not involve a change

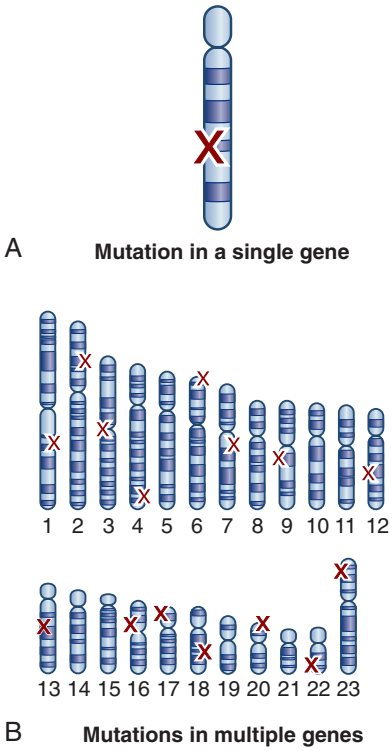

FIG. 13-6 A, Genetic disorders can be caused by a mutation in a single gene (e.g., sickle cell disease, cystic fibrosis, hemophilia). **B,** Most genetic disorders are multifactorial genetic disorders caused by a combination of mutations in multiple genes, often interacting with environmental factors. Examples include cancer, diabetes mellitus, obesity, and hypertension.

in DNA sequence. Epigenetics focuses on how and when particular genes are expressed. The expression of genes can be affected both positively and negatively by environmental factors, such as exercise, diet, chemicals, toxins, or smoking. Epigenetic changes can be inherited.

Chromosome Disorders. *Chromosome disorders* are caused by structural changes within chromosomes or by an excess or deficiency of the genes that are located on chromosomes. For example, Down syndrome is caused by an extra copy of chromosome 21 (called trisomy 21), so there are three copies of this chromosome instead of two. In Down syndrome there is no individual abnormal gene on the chromosome.

Chronic myelocytic leukemia can be caused by a chromosomal translocation, in which portions of two chromosomes (chromosomes 9 and 22) are exchanged. This translocation is called the Philadelphia chromosome.

Throughout the book, genetic disorders are highlighted in Genetics in Clinical Practice boxes, Genetic Risk Alert boxes (in the assessment chapters), and Genetic Links content (in the management chapters).

GENETIC TESTING

Genetic testing includes any procedure done to analyze chromosomes, genes, or any gene product that can determine whether a mutation or predisposition to a condition exists. Genetic tests have been developed for more than 2000 diseases. Samples from a person's blood, skin, hair, or saliva can be used to obtain samples for genetic testing. Tissues and cells can also be obtained prenatally.

GENETICS IN CLINICAL PRACTICE

Genetics in Clinical Practice Boxes Throughout Book

GENETIC DISORDER	CHAPTER	PAGE
α_1-Antitrypsin (AAT) Deficiency	29	582
Alzheimer's Disease (AD)	60	1446

Ovarian Cancer	54	1295
Polycystic Kidney Disease (PKD)	46	1083
Sickle Cell Disease	31	645
Types 1 and 2 Diabetes Mellitus	49	1155

Genetic testing has been very useful in health care (Table 13-3). Most tests assess single genes and are used to diagnose genetic disorders such as cystic fibrosis or Duchenne muscular dystrophy.[7] Some genetic tests look at rare inherited mutations of otherwise protective genes, such as *BRCA1* and *BRCA2*, which are responsible for some types of hereditary breast and ovarian cancers.

The results of these tests are used in diagnosing an illness or risk for a disorder, and provide the basis for appropriate treatments. Other genetic tests identify people at high risk for conditions that may be preventable. For example, monitoring for and removing polyps or the entire colon in those inheriting a gene for familial adenomatous polyposis (FAP) has saved many lives. (FAP is discussed in Chapter 43 on p. 985.)

Genetic testing of individuals may raise both ethical and social issues. People considering genetic testing should be aware that test results in their medical records might not be kept private. However, the Genetic Information Nondiscrimination Act (GINA) protects people from discrimination by employers and health insurance companies.

If an individual has genetic testing, it may uncover information that may also affect a family member who was not tested. These individuals are frequently not a part of the decision-making process to undergo testing. Similarly, if a whole family is tested, the results may indicate that the biologic relationship is not what the family believed it to be. Some tests are used to help guide health care providers' recommendations for treatment in consultation with the patient (e.g., *BRCA* testing). Other tests allow families to make the decision about not having children with devastating diseases (e.g., cystic fibrosis) or identify people at high risk for conditions that may be prevented by monitoring or having prophylactic surgery (e.g., familial adenomatous polyposis [FAP]).

Currently, many genetic tests are available from testing laboratories. In most cases insurance companies will not cover the cost of genetic testing. For more information about genetic testing, see *www.cdc.gov/dls/moleculartesting*.

TABLE 13-3 USE OF GENETIC TESTS*

Type of Test	Description	Examples
Diagnostic testing	• Used to diagnose, rule out, or confirm a specific genetic or chromosomal condition. • Used to confirm findings when patient's signs and symptoms suggest a genetic disorder. • Can be performed at any time during a person's life, but is not available for all genes or all genetic conditions.	Cystic fibrosis Sickle cell disease Polycystic kidney disease Hemophilia Familial hypercholesterolemia
Carrier screening	• Can be used to identify unaffected individuals who carry one copy of a gene. • Offered to individuals who have a family history of a genetic disorder and to people in ethnic groups with an increased risk of specific genetic conditions. • If both parents are tested, the test can provide information about a couple's risk of having a child with a genetic condition.	Cystic fibrosis Sickle cell disease Hemophilia
Preimplantation genetic diagnosis (PGD)	• Fertilized embryos tested before implantation and pregnancy. • Allows embryos free of particular disorders to be placed into the uterus. • Embryos that test positive for genetic disorders can be destroyed.	For individuals known to have or be a carrier for a genetic mutation (e.g., Huntington's disease)
Prenatal diagnostic testing	• Fluid obtained from amniocentesis or tissue from chorionic villus used to obtain fetal cells. • Used to detect changes in genes or chromosomes of fetus before birth. • Type of testing offered to couples with an increased risk of having a baby with a genetic or chromosomal disorder. • Can decrease a couple's uncertainty or help them decide whether to terminate the pregnancy.	Down syndrome or other genetic alterations in fetuses
Newborn screening	• Most widespread use of genetic testing. • Early intervention to treat these disorders can eliminate or reduce symptoms that might otherwise cause a lifetime of disability.	Phenylketonuria Congenital hypothyroidism Cystic fibrosis
Presymptomatic testing	• Used to detect genetic mutations associated with disorders that appear later in life. • Can be helpful to people who have a family member with a genetic disorder, but who have no features of the disorder themselves at the time of testing. • Results can provide information about a person's risk of developing a specific disorder and help with making decisions about treatment.	Huntington's disease Adult polycystic kidney disease Hemochromatosis Familial adenomatous polyposis Hereditary nonpolyposis colorectal cancer syndrome
Predictive testing	• Can identify mutations that increase a person's risk of developing disorders. • If results are positive, person can have prophylactic measures (e.g., mastectomy, oophorectomy) to prevent development of cancer.	Breast cancer Ovarian cancer
Forensic testing	• Done to identify an individual for legal purposes.	Identify crime or victims in catastrophic situations Rule out or implicate a crime suspect
Parental testing	• Establish biologic relationships between people.	Paternity testing
Pharmacogenetic testing	• Identifies genetic variations that influence a person's response to drugs. • Results provide information to help select drug therapy that is best for the person.	warfarin (Coumadin) dose

*The laboratory performing the tests must, by law, keep your personal information and test results confidential.

GENETICS IN CLINICAL PRACTICE

Genetic Information Nondiscrimination Act (GINA)

What Is GINA?

The Genetic Information Nondiscrimination Act (GINA) prohibits discrimination in health care coverage and employment based on genetic information.

Why Was GINA Needed?

- Decreases concerns about discrimination that might prevent people from getting genetic tests.
- Enables people to take part in research studies without fear that their DNA information might be used against them in the workplace or prevent them from getting health insurance.

What Is a Genetic Test?

- An analysis of human genes (DNA, RNA), chromosomes, proteins, or metabolites that detects genotypes, mutations, or chromosomal changes.

What Is Genetic Information?

- Any information about a person's genetic tests, family members' genetic tests, and family history of a genetic disease or disorder.
- Referral of a person or family for, or use of, genetic services and participation in clinical research that involves genetic services.

What Does GINA Do?

- Prevents health insurers from denying health insurance coverage, adjusting premiums, and discriminating against a person based solely on his or her genetic or family history information.
- Prevents health insurers from requesting that a person have a genetic test.
- Prohibits most employers from using genetic information for hiring, firing, or promotion decisions, and for any decisions regarding terms of employment.
- GINA's health coverage nondiscrimination protection does not extend to life insurance, disability insurance, and long-term care insurance.

For more information see

- *www.genome.gov/Pages/PolicyEthics/GeneticDiscrimination/GINAInfoDoc.pdf*
- Frequently Asked Questions about GINA at *www.dnapolicy.org/gina/faqs.html*

Interpreting Genetic Test Results

The results of genetic tests are not always straightforward, which often makes them challenging to interpret and explain. When interpreting test results, health care professionals need to consider a person's medical history, family history, and the type of genetic test that was done.

A *positive test* result means that the laboratory found a change in a particular gene, chromosome, or protein that was being tested. Depending on the purpose of the test, this result may confirm a diagnosis (e.g., Huntington's disease), indicate that a person is a carrier of a particular genetic mutation (e.g., cystic fibrosis), identify an increased risk of developing a disease (e.g., breast cancer), or suggest a need for further testing. A positive result of a predictive or presymptomatic genetic test usually cannot establish the absolute risk of developing a disorder. In addition, a positive test cannot predict the course or severity of a condition.

In some situations it is difficult to interpret a positive result because some people who have the genetic mutation being tested never develop the disease. For example, having the apolipoprotein E-4 *(Apo E-4)* allele increases the risk of developing Alzheimer's disease. However, many people who test positive for *Apo E-4* never develop Alzheimer's disease (see Chapter 60).

A *negative test* result means that the laboratory did not find an altered form of the gene, chromosome, or protein under consideration. This result can indicate that a person is not affected by a particular disorder, is not a carrier of a specific genetic mutation, or does not have an increased risk of developing a certain disease. However, it is possible that the test missed a disease-causing genetic alteration, since many tests cannot detect all the genetic changes that cause a particular disorder. Further testing may be required to confirm a negative result.

ETHICAL/LEGAL DILEMMAS

Genetic Testing

Situation

A 30-year-old woman informs you that she is 3 months' pregnant. She has two children with her current husband. This pregnancy was unplanned, and her youngest child has cystic fibrosis (CF). She expresses concern regarding the possibility of having another child with CF. She mentions that she would like to have genetic testing on her fetus. Her husband asks you what the likelihood is of having another child with CF.

Ethical/Legal Points for Consideration

- With genetic testing, the patient and her family can find out whether their child will have CF. The woman and her husband can then make an informed decision.
- Genetic counseling is recommended before and after obtaining genetic testing because of the complexity of the information and the emotional issues involved with implications and options.
- Knowing that CF is an autosomal recessive condition, you can use Punnett squares (see Fig. 13-9) or a family pedigree (see Figs. 13-4 and 13-5) to show the woman and her husband the probability of having another child with CF.

Discussion Questions

1. What information would you give the patient and her husband regarding genetic testing in order for them to make an informed decision?
2. What options are available for this couple?
3. How would you assist this couple as they are considering terminating the pregnancy if the results of the genetic testing reveal that the fetus will have CF?

Direct-to-Consumer Genetic Tests

Direct-to-consumer genetic tests (at-home testing) are marketed directly to people (consumers) via television, print advertisements, or the Internet. The test kit is mailed to the person instead of being ordered through a health care provider's office. The test typically involves collecting a DNA sample at home, often by swabbing the inside of the cheek, and mailing the sample back to the laboratory. In some cases the person must visit a health clinic to have blood drawn.

Consumers are notified of their results by mail or over the telephone, or the results are posted online. In some cases a genetic counselor or other health care provider is available to explain the results and answer questions. The price for at-home genetic testing ranges from several hundred dollars to more than $1000.

Direct-to-consumer genetic tests have significant risks and limitations. Consumers are vulnerable to being misled by the results of unproven or invalid tests. Without guidance from a health care provider, they may make important decisions about disease treatment or prevention based on inaccurate, incomplete, or misunderstood information about their health. Consumers may also experience an invasion of genetic privacy if testing companies use their genetic information in an unauthorized way.

If your patients are considering using these kinds of genetic tests, let them know that they first need to discuss the issue with their health care provider or a genetic counselor. Patient teaching related to genetic testing is presented in Table 13-4.

Genetic Technology

DNA Finger Printing. DNA (genetic) finger printing begins by extracting DNA from the cells in a sample of blood, saliva, semen, or other appropriate fluid or tissue. *Polymerase chain reaction* (PCR) is a quick, easy method to provide unlimited copies of a DNA or RNA sequence using only a small amount of sample. PCR involves the artificial replication of a DNA or RNA sequence. The DNA or RNA strands can be separated to form new templates that are used for replication.[8]

PCR is a key element in *genetic finger printing*. It is an essential technique to finding mutations in genes. It is also used extensively in forensic medicine to identify DNA of criminal suspects by using samples from blood, hair, saliva, and semen. PCR has also been used in finding evidence to free innocent prisoners and in paternity testing.

PCR can also be used as a confirmatory test in HIV testing. This is especially important when an infant of a mother who is HIV-antibody positive also tests HIV positive. In this situation it is not known whether the antibodies from the infant's blood are from the baby or the mother. PCR techniques can be used on the baby's lymphocytes to determine whether the baby is infected with HIV.

DNA Microarray (DNA Chip). Although all of a person's somatic cells contain identical genetic material, the same genes are not active in every cell. Studying which genes are active and which are inactive in different cell types helps to understand (1) how these cells function normally and (2) how they are affected when various genes do not perform properly.

Gene expression profiling uses a technology called *DNA microarrays* (DNA chips). This technology is used to measure the expression levels of large numbers of genes simultaneously or to genotype multiple regions of a genome. The chips are laid

TABLE 13-4 PATIENT & FAMILY TEACHING GUIDE

Genetic Testing

Genetic Counselors

- Individuals who are considering genetic testing should meet with a genetic counselor who is specially trained in medical genetics and counseling.
- Counseling is advised to help you understand the purpose of genetic testing, considerations before testing, and the emotional and medical impact of the test results.
- Genetic counseling can help you understand the pros and cons of genetic testing before making a decision to undergo a genetic test.

General Information

The following includes some important general information about genetic testing.

- Genetic testing can be expensive and may not be included in your medical insurance policy.
- Genetic testing may determine whether you are predisposed to developing an inherited disease.
- A particular genetic test will only tell you whether there is a specific genetic variant or mutation. Positive tests do not mean you will develop that disease or disorder. Neither can the results tell you when you will develop the disease.
- If a genetic test demonstrates a genetic predisposition to an inherited disorder, the news can be depressing.
- Knowledge of a genetic predisposition to a disease may give you the motivation to take preventive measures (e.g., taking drugs for familial hypercholesterolemia) or make lifestyle changes to lower the risk of a disease (e.g., exercising to decrease the risk of type 2 diabetes).
- If a genetic test reveals a strongly negative result, you probably will not develop that disease.
- If a genetic test reveals you are at risk for a specific genetic disorder, there is the possibility that other family members may also be at risk.
- If a genetic test reveals you are at risk for developing an inherited disease, whether or not you decide to share that information with family members is both a personal and an ethical decision that you will have to make.
- Genetic testing may provide important information that you can use when making decisions about having children.

out by robots that can position DNA fragments so precisely that more than 20,000 of them can fit on one microscope slide.

Then fluorescent-tagged molecules are washed over the DNA fragments. Some molecules (with green fluorescent tags) bind to their complementary sequence. These molecules can be identified because they glow under fluorescent light when scanned using automated equipment. Complete patterns of gene activity can be captured with this technology.

Genome-Wide Association Study (GWAS)

Genome-wide association study (GWAS) is an approach that involves rapidly scanning complete sets of DNA, or genomes, of many individuals to find genetic variations associated with the development or progression of a particular disease.

Until recently, researchers looked at single genes and the proteins that they encode. With GWAS, researchers study large numbers of genes and proteins, including how they act and interact. This provides a more complete picture of what goes on in a person. After the genetic associations are identified, researchers may be able to learn how to stop or jump-start genes on demand, change the course of a disease, or prevent it from ever happening.[4,8] GWAS is particularly useful in finding genetic variations that contribute to multifactorial inherited disorders such as asthma, cancer, diabetes, and heart disease.

To carry out a GWAS, researchers use two groups of participants: people with the disease being studied and similar people without the disease. Each person's complete set of DNA, or genome, is then purified from the blood or cells, placed on tiny chips, and scanned on automated laboratory machines. The machines quickly survey each participant's genome for strategically selected markers of genetic variation.

If certain genetic variations are found to be significantly more common in people with the disease compared to people without the disease, the variations are said to be "associated" with the disease. The associated genetic variations can serve as powerful pointers to the region of the human genome where the disease-causing problem resides.

The potential impact of GWAS is substantial, since it lays the groundwork for personalized medicine, in which the current one-size-fits-all approach to health care gives way to more customized strategies. Tools such as GWAS can provide patients with individualized information about their risks of developing certain diseases. The information will help health care professionals tailor prevention programs to each person's unique genetic makeup.

PHARMACOGENETICS AND PHARMACOGENOMICS

Patients vary widely in their response to drugs. Although the reasons for this are complex, genetic factors may account for a large percentage of patient variability in response to individual drugs. **Pharmacogenetics** is the study of genetic variability of drug responses related to variations in single genes. **Pharmacogenomics** is similar to pharmacogenetics except that it involves multiple genes associated with variability in drug response. These two terms are frequently used interchangeably in describing the relationship between pharmacology and genetic variability in determining an individual's response to drugs.

Pharmacogenetic and pharmacogenomic studies can potentially lead to drugs that can be tailor-made or adapted to each person's particular genetic makeup.[9] Table 13-5 has examples of pharmacogenetics.

One important area of study has been focused on the cytochrome P450 (CYP450) family of major enzymes, which are important in *drug metabolism*. Alterations in the *CYP450* gene can affect how the liver breaks down certain drugs, such as warfarin (Coumadin). People with a less active form of the enzyme (who metabolize the drug slowly) might get too much of the drug, whereas people with a more active form of the enzyme (who metabolize the drug quickly) might get too little of the drug. Too much warfarin can lead to internal bleeding, whereas too little warfarin may still allow blood clots to form. Pharmacogenetic testing can assist health care providers in prescribing the right amount of a medicine based on a patient's particular genetic makeup (Fig. 13-7).

Currently a genetic test for identifying *CYP450* polymorphisms is available that has been approved by the U.S. Food and Drug Administration (FDA). In addition to maximizing the safety and effectiveness of drugs, this type of genetic testing can lead to individualized drug therapy.

Health care providers are starting to use pharmacogenomic information to prescribe drugs, but at this time such tests are

TABLE 13-5 EXAMPLES OF PHARMACOGENETICS

Drug	Role of Pharmacogenetics
trastuzumab (Herceptin)	• In breast cancer, drug only works for women whose tumors have genes that lead to the overproduction of a protein called HER-2. • Drug is a monoclonal antibody to HER-2. After the antibody attaches to the antigen, it kills the cells. • Genetic testing provides information on which patients are good candidates for treatment with drug. • Drug does not work for patients whose tumor genes do not express HER-2.
crizotinib (Xalkori)	• Drug used to treat patients with late-stage (locally advanced or metastatic), non–small cell lung cancers (NSCLC) who express the abnormal anaplastic lymphoma kinase *(ALK)* gene. • *ALK* gene abnormality causes cancer development and growth. • Crizotinib works by blocking certain proteins called kinases, including the protein produced by the abnormal *ALK* gene. • Drug was approved for use with a companion genetic diagnostic test that determines whether a patient with NSCLC has the abnormal *ALK* gene.
vemurafenib (Zelboraf)	• Approved for patients with late-stage (metastatic) or unresectable melanoma. • Indicated for the treatment of patients with melanoma whose tumors express a gene mutation called *BRAF V600E*. • To be considered for treatment, patients must first have genetic testing to determine whether melanoma cells have the *BRAF V600E* mutation.
warfarin (Coumadin)	• Genetic variants in the genes *VKORC1* and cytochrome P450 2C9 *(CYP2C9)* have a significant impact on people's sensitivity to warfarin. • Individuals with particular variations in these genes require a lower warfarin dose to maintain therapeutic levels of anticoagulation. • Individuals with other variations require higher doses. • Together these genetic variations explain about 50% of the required dose difference between individuals. • Testing for patient's *CYP2C9* and *VKORC1* genotype information can assist in selecting the starting dose.
abacavir (Ziagen)	• Some people are at greater risk for serious allergic reactions when first starting treatment with this drug. • Genetic testing for *HLA-B*5701* before taking the drug can identify people who carry a genetic marker that is associated with life-threatening hypersensitivity reactions.
clopidogrel (Plavix)	• For clopidogrel to work, cytochrome P450 enzymes in the liver (particularly CYP2C19) must convert the drug to its active form. • About 2% to 14% of the population are poor metabolizers, and these patients may not receive the full benefits of the drug. • Genetic tests are available to identify genetic differences in CYP2C19 function.

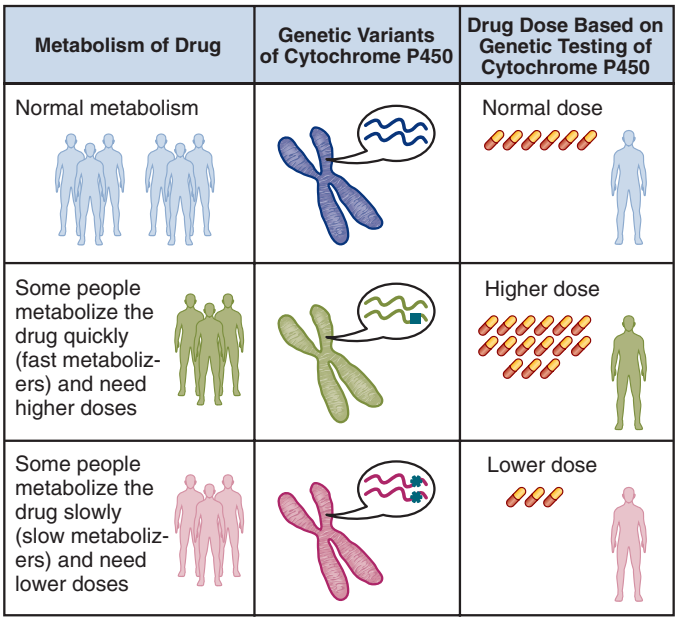

FIG. 13-7 Individuals respond differently to the drug warfarin (Coumadin). The diversity of responses is partially due to genetic variants in one of the cytochrome *P450* genes.

routine for only a few diseases or disorders (examples are presented in Table 13-5). However, given the field's rapid growth, pharmacogenomics may soon lead to personalized medicine and individualized drug therapy to manage heart disease, cancer, asthma, depression, and many other common diseases.

GENE THERAPY

Gene therapy is an experimental technique that uses genes to treat or prevent disease. Gene therapy is an approach to treating potentially lethal and disabling diseases that are caused by single gene deficiencies. With specialized techniques, gene expression can be manipulated to correct the problem in the particular patient, although the correction will not be passed along to offspring of that person. Approaches to gene therapy include:[10]

- Replacing a mutated gene with a healthy copy of the gene
- Inactivating, or "knocking out," a mutated gene that is functioning improperly
- Introducing a new gene into the body to help fight a disease

A gene that is inserted directly into a cell usually does not function. A carrier molecule called a *vector* must be used to deliver the therapeutic gene to the patient's target cells. Currently, the most common vector is a virus that has been genetically altered to carry normal human DNA. The vector can be injected or given IV directly into specific tissue. The vector unloads its genetic material containing the therapeutic human gene into the target cell. If the treatment is successful, the new gene will make a functional protein and restore the target cell to a normal state. A diagram of gene therapy is depicted in Fig. 13-8.

Although gene therapy is a promising treatment option for a number of diseases (including inherited disorders, some types of cancer, and certain viral infections), the technique remains risky and is still under study to make sure that it will be safe

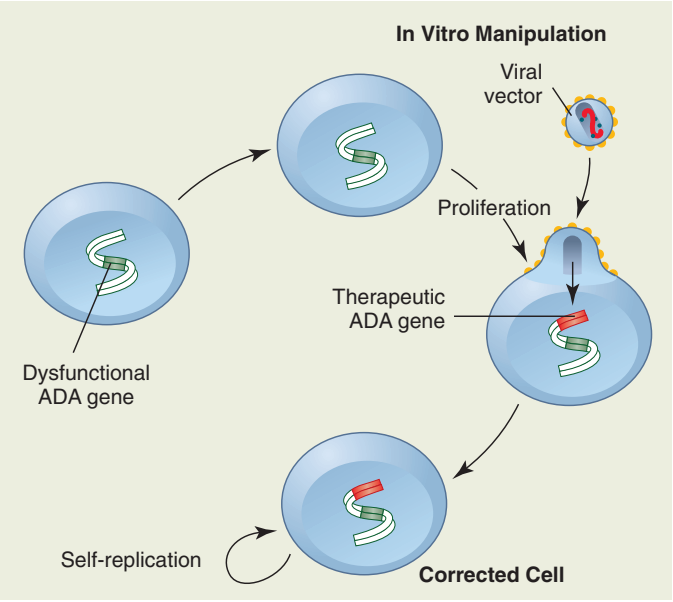

FIG. 13-8 Gene therapy for adenosine deaminase *(ADA)* deficiency attempts to correct this immunodeficiency state. The viral vector containing the therapeutic ADA gene is inserted into the patient's lymphocytes. These cells can then make the ADA enzyme.

and effective. Gene therapy is currently only being tested for the treatment of diseases that have no other cures.[10]

STEM CELL THERAPY

Stem cells are the subject of much discussion because they may offer treatment for many diseases. The use of stem cells may allow for the regeneration of lost tissue and restoration of function in various diseases.

Stem cells are unspecialized cells in the body that have the ability to (1) remain in their unspecialized state and divide or (2) differentiate and develop into specialized cells such as a brain cell or a muscle cell. In some body organs such as the gastrointestinal (GI) tract and bone marrow, stem cells divide to repair and replace damaged or old tissues. In other organs such as the pancreas and the heart, stem cells divide only under special conditions.

Stem cells can be divided into two types: embryonic and adult, or somatic. *Embryonic stem cells* come from the embryo at a very early stage in development (4 to 5 days old) and have the ability to become any one of the hundreds of types of cells in the human body. These stem cells can be stimulated to differentiate into any type of tissue (skin, liver, kidney, blood, etc.) found in an adult human.

Adult stem cells are undifferentiated cells that are found in small numbers in many adult organs and tissues, including brain, bone marrow, peripheral blood, blood vessels, skeletal muscle, skin, teeth, heart, GI tract, liver, ovarian epithelium, and testes. They are thought to reside in a specific area of each tissue called a *stem cell niche*. Adult stem cells are more limited than embryonic stem cells in their potential (e.g., stem cells from liver may only develop into more liver cells).

The primary roles of adult stem cells in the body are to maintain and repair tissues in which they are found. They are usually thought of as multipotent cells, giving rise to a closely related family of cells within the tissue. For example, skin stem cells produce new skin cells. Hematopoietic stem cells found within the bone marrow are capable of forming all of the various blood cells. These cells are prolific by design and are already being used for bone marrow transplants (see Chapter 16).

Medical researchers are investigating the use of stem cells to repair or replace damaged body tissues, similar to whole organ transplants. Currently not enough donated organs are available to meet the demand for transplants. In organ transplants, when tissues from a donor are placed into a patient's body, the patient's immune system may react and reject the donated tissue as "foreign." However, using stem cells presents less risk of this immune rejection, and the therapy may be more successful.

In addition, stem cells could be directed to differentiate into specific cell types. They would then become a renewable source of replacement cells and tissues to treat conditions such as Alzheimer's disease, spinal cord injury, stroke, burns, heart disease, diabetes, osteoarthritis, and rheumatoid arthritis. It may become possible to generate healthy heart muscle cells in the laboratory and then transplant those cells into patients with chronic heart disease. Whether these cells can generate heart muscle cells or stimulate the growth of new blood vessels is under investigation.[11]

NURSING MANAGEMENT GENETICS AND GENOMICS

You need to be knowledgeable about the fundamentals of genetics and genomics.[12,13] By understanding the profound influence that genetics has on health and illness, you can assist the patient and family in making critical decisions related to genetic issues, such as genetic testing. You also need to collaborate with the health care team to involve a genetic nurse or a genetic counselor.

A genetic nurse is a licensed professional nurse with special education and training in genetics. Nurses with GCN after their names are baccalaureate-prepared licensed registered nurses who have received specialty credentialing as a Genetic Clinical Nurse (GCN). Nurses with APNG after their names are licensed registered nurses with a master's degree who have received specialty credentialing as an Advanced Practice Nurse in Genetics (APNG).

As a basic professional nurse, you should be an advocate for patients and families by facilitating access to genetics resources. In addition, you need to provide or reinforce accurate information pertaining to genetics or a genetic disease or concern. This information should be tailored to the patient based on culture, religion, knowledge level, literacy, and preferred language.[14]

You can identify and assess inheritance patterns and explain them to the patient and the family through the use of family pedigrees (see Figs. 13-4 and 13-5) and Punnett squares (Fig. 13-9). Maintain the patient's confidentiality and respect the patient's values and beliefs because genetic information may have major health and social implications.

Genetic testing may raise many psychologic and emotional issues. Knowledge of carrier status of a genetic disorder may influence a person's decisions for a career, marriage, and childbearing. It may also affect significant others in grappling with serious life and health care issues. For example, how should a wife deal with a husband who has tested positive for Hunting-

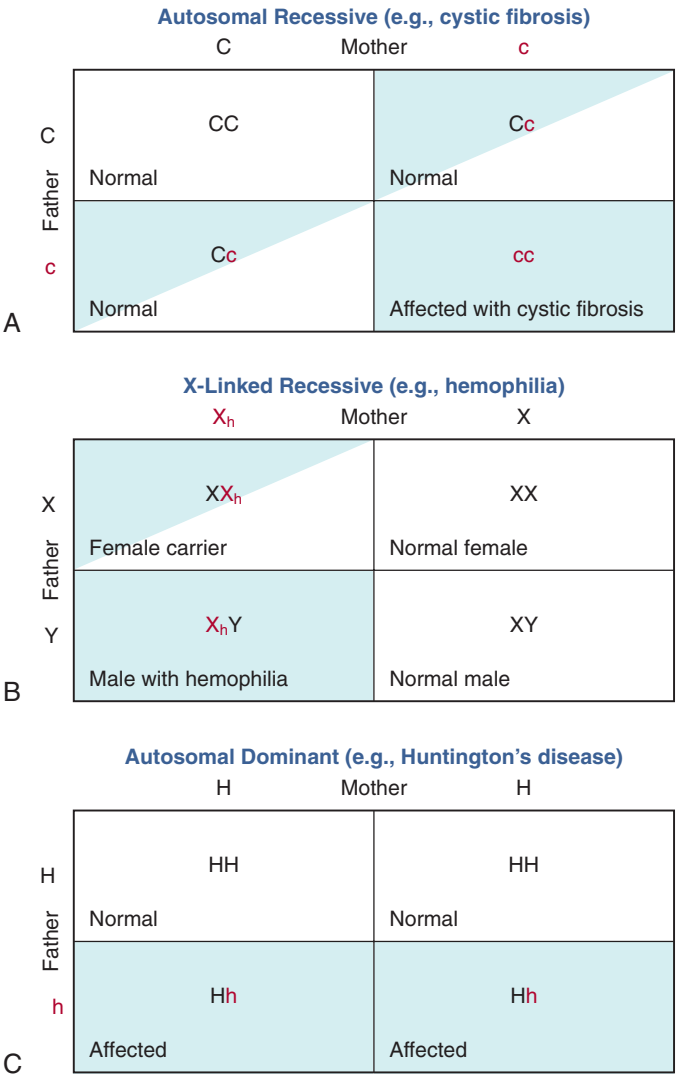

FIG. 13-9 Punnett squares illustrate inheritance possibilities. **A,** If the mother and father are both carriers for cystic fibrosis, there is a 25% chance that offspring will have cystic fibrosis. **B,** If the mother is a carrier for the hemophilia gene and the father has a normal genotype, there is a 50% chance that any male offspring will have hemophilia. There is a 50% chance that any female offspring will be a carrier. **C,** If the mother has a normal genotype and the father has Huntington's disease, there is a 50% chance that offspring will have the disease.

ton's disease and shows early signs of cognitive impairment but does not yet show any other neurologic manifestations of the disease? Should their children be tested for the disease? A 43-year-old woman who has a family history of breast cancer and is now diagnosed with breast cancer wants to know if she and her two teenage daughters should have *BRCA* testing. What do you tell her?

Furthermore, there are ethical concerns. Who should know the results of a genetic test? Who should protect the privacy of individuals' test results and prevent individuals from possible discrimination? Genetic information should not be misused to label individuals or particular ethnic groups. Close attention must be paid to better understand the psychosocial needs of individuals and societal responses and health care policy related to genetic testing.

People may be reluctant to share or disclose information about family history or genetic test results. They fear they are vulnerable to discrimination based on their DNA. Inform your patients about the Genetic Information Nondiscrimination Act (GINA), which protects them from discrimination by employers and health care insurance companies (see Genetics in Clinical Practice Box on p. 196).

Resources on genetics for nurses and nurse educators are available in the list of resources at the end of this chapter.

NURSING ASSESSMENT
FAMILY HISTORY

Family history is one of the strongest influences on a person's risk of developing genetic-related disorders such as heart disease, stroke, diabetes, or cancer. Even though a person cannot change his or her genetic makeup, knowing the family history can help in the prevention or early diagnosis and treatment of a disorder. For example, it is important to monitor cholesterol levels in a person with a family history of familial hypercholesterolemia.

The key features of a family history that may increase a person's risk for genetic-related diseases are

- Disease in more than one close relative
- Disease that does not usually affect a certain gender (e.g., breast cancer in a male)
- Diseases that occur at an earlier age than expected (e.g., myocardial infarction before age 35)
- Certain combinations of diseases within a family (e.g., breast and ovarian cancer, heart disease and diabetes)

If a family has one or more of these features, the family history may hold important clues about a person's risk for a genetic disease. People with a family history of disease may have the most to gain from lifestyle changes and screening tests. People cannot change their genes, but they can change unhealthy behaviors (e.g., smoking, poor eating habits). They can also get screening tests to detect diseases and disease risk factors (e.g., elevated cholesterol, hypertension) that can be treated.

Genetic Risk Alert boxes in the assessment chapters in this book highlight a patient's risks related to genetic diseases and disorders. Use the information in these boxes when obtaining a nursing history.

Family health history is a written or graphic record of the diseases and health conditions present in one's family (see Chapter 3). A useful family health history shows three generations of a person's biologic relatives, the age of diagnosis of a disease, and the age and cause of death of deceased family members. A family health history is a useful tool for understanding health risks and preventing disease in individuals and their close relatives.

Talk with your own family members about your family's health history. Record this information and update it periodically so you and your family members will have organized and accurate information ready to share with your health care provider. Family health history information may help health care providers determine which tests and screenings are recommended to help you and your family know their health risk.

To help individuals collect and organize their family history information, the Centers for Disease Control and Prevention (CDC) has collaborated with the U.S. Surgeon General and other federal agencies to develop a Web-based tool called *My Family Health Portrait* (*https://familyhistory.hhs.gov/fhh-web/home.action*).

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. If a person is heterozygous for a given gene, it means that the person
   a. is a carrier for a genetic disorder.
   b. is affected by the genetic disorder.
   c. has two identical alleles for the gene.
   d. has two different alleles for the gene.
2. Common causes of genetic mutations include *(select all that apply)*
   a. DNA damage from toxins.
   b. DNA damage from UV radiation.
   c. inheritance of altered genes from father.
   d. inheritance of altered genes from mother.
   e. inheritance of somatic mutations from either parent.
3. A father who has an X-linked recessive disorder and a wife with a normal genotype will
   a. pass the carrier state to his male children.
   b. pass the carrier state to all of his children.
   c. pass the carrier state to his female children.
   d. not pass on the genetic mutation to any of his children.
4. What characterizes multifactorial genetic disorders?
   a. Genetic testing available for most disorders
   b. Commonly caused by single gene alterations
   c. Many family members report having the disorder
   d. Caused by complex interactions of genetic and environmental factors
5. If a person tests positive for a genetic mutation, it means *(select all that apply)*
   a. that the laboratory found an alteration in a gene.
   b. that the person is predisposed to develop a genetic disease.
   c. that the person will develop the disease at some point in time.
   d. there is the possibility that other family members may also be at risk.
   e. that the person should not have any children or any additional children.
6. What role does pharmacogenetics have in health care?
   a. It can assess individual variability to many drugs.
   b. It can be used to determine the effectiveness of a drug.
   c. It provides important assessment data for gene therapy.
   d. It can assess the variability of drug responses due to single genes.
7. A couple who recently had a son with hemophilia A is consulting with a nurse. They want to know if their next child will have hemophilia A. The nurse can tell the parents that if their child is a
   a. boy, he will have hemophilia A.
   b. boy, he will be a carrier of hemophilia A.
   c. girl, she will be a carrier of hemophilia A.
   d. girl, there is a 50% chance she will be a carrier of hemophilia A.

1. d, 2. a, b, c, d, 3. c, 4. d, 5. a, d, 6. d, 7. d

LEARNING OUTCOMES

1. Describe the functions and components of the immune system.
2. Compare and contrast humoral and cell-mediated immunity, including lymphocytes involved, types of reactions, and effects on antigens.
3. Characterize the five types of immunoglobulins.
4. Differentiate among the four types of hypersensitivity reactions in terms of immunologic mechanisms and resulting alterations.
5. Identify the clinical manifestations and emergency management of a systemic anaphylactic reaction.
6. Describe the assessment and collaborative care of a patient with chronic allergies.
7. Explain the relationship between the human leukocyte antigen system and certain diseases.
8. Describe the etiologic factors, clinical manifestations, and treatment modalities of autoimmune diseases.
9. Describe the etiologic factors and categories of immunodeficiency disorders.
10. Differentiate among the types of rejections following transplantation.
11. Identify the types and side effects of immunosuppressive therapy.

KEY TERMS

hypersensitivity reactions, p. 209
immunocompetence, p. 209
immunodeficiency, p. 218
immunosuppressive therapy, p. 221

This chapter discusses the normal immune response and the altered immune responses of hypersensitivity (including allergies), autoimmunity, and immunodeficiency. Histocompatibility, organ transplantation, and immunosuppressive therapy are also presented.

NORMAL IMMUNE RESPONSE

Immunity is the body's ability to resist disease. Immune responses serve the following three functions:

1. *Defense:* The body protects against invasions by microorganisms and prevents the development of infection by attacking foreign antigens and pathogens.
2. *Homeostasis:* Damaged cellular substances are digested and removed. Through this mechanism, the body's different cell types remain uniform and unchanged.
3. *Surveillance:* Mutations continually arise in the body but are normally recognized as foreign cells and destroyed.

Antigens

An **antigen** is a substance that elicits an immune response. Most antigens are composed of protein. However, other substances such as large polysaccharides, lipoproteins, and nucleic acids can act as antigens. All of the body's cells have antigens on their surface that are unique to that person and enable the body to recognize itself. The immune system normally

Whitney School of Nursing, Laramie, Wyoming.

becomes "tolerant" to the body's own molecules. Therefore it is nonresponsive to "self" antigens.

Types of Immunity

Immunity is classified as innate or acquired.

Innate Immunity. *Innate immunity* is present at birth, and its primary role is first-line defense against pathogens. This type of immunity involves a nonspecific response, and neutrophils and monocytes are the primary white blood cells (WBCs) involved. Innate immunity is not antigen specific so it can respond within minutes to an invading microorganism without prior exposure to that organism.

Acquired Immunity. *Acquired immunity* is the development of immunity, either actively or passively (Table 14-1).

Active Acquired Immunity. *Active acquired immunity* results from the invasion of the body by foreign substances such as microorganisms and subsequent development of antibodies and sensitized lymphocytes. With each reinvasion of the microorganisms, the body responds more rapidly and vigorously to fight off the invader. Active acquired immunity may result naturally from a disease or artificially through immunization with a less virulent antigen. Because antibodies are synthesized, immunity takes time to develop but is long lasting.

Passive Acquired Immunity. *Passive acquired immunity* implies that the host receives antibodies to an antigen rather than synthesizing them. This may take place naturally through the transfer of immunoglobulins across the placental membrane from mother to fetus. Artificial passive acquired immunity occurs through injection with gamma globulin (serum antibodies). The benefit of this immunity is its immediate effect. Unfortunately, passive immunity is short lived because the person does not synthesize the antibodies and consequently does not retain memory cells for the antigen.

Lymphoid Organs

The lymphoid system is composed of central (or primary) and peripheral lymphoid organs. The *central lymphoid organs* are the thymus gland and bone marrow. The *peripheral lymphoid organs* are the lymph nodes; tonsils; spleen; and gut-, genital-, bronchial-, and skin-associated lymphoid tissues (Fig. 14-1).

Lymphocytes are produced in the bone marrow and eventually migrate to the peripheral organs. The thymus is involved in the differentiation and maturation of T lymphocytes and is therefore essential for a cell-mediated immune response. During childhood the thymus is large. It shrinks with age, and in the older person the thymus is a collection of reticular fibers, lymphocytes, and connective tissue.

When antigens are introduced into the body, they may be carried by the bloodstream or lymph channels to regional lymph nodes. The antigens interact with B and T lymphocytes and macrophages in the lymph nodes. The two important functions of lymph nodes are (1) filtration of foreign material brought to the site and (2) circulation of lymphocytes.

The tonsils are an example of lymphoid tissue. The spleen, a peripheral lymph organ, is important as the primary site for filtering foreign antigens from the blood. It consists of two kinds of tissue: white pulp containing B and T lymphocytes and red pulp containing erythrocytes. Macrophages line the pulp and sinuses of the spleen.

Lymphoid tissue is found in the submucosa of the gastrointestinal (GI) (gut-associated), genitourinary (genital-associated), and respiratory (bronchial-associated) tracts. This tissue protects the body surface from external microorganisms.

The skin-associated lymph tissue primarily consists of lymphocytes and Langerhans' cells (a type of dendritic cell) found in the epidermis of skin. When Langerhans' cells are depleted, the skin can neither initiate an immune response nor support a skin-localized delayed hypersensitivity reaction.

Cells Involved in Immune Response

Mononuclear Phagocytes. The *mononuclear phagocyte system* includes monocytes in the blood and macrophages found

TABLE 14-1 TYPES OF ACQUIRED SPECIFIC IMMUNITY

Type	Natural	Artificial
Active	Natural contact with antigen through clinical infection (e.g., recovery from chickenpox, measles, mumps)	Immunization with antigen (e.g., immunization with live or killed vaccines)
Passive	Transplacental and colostrum transfer from mother to child (e.g., maternal immunoglobulins in neonate)	Injection of serum from immune human (e.g., injection of human gamma globulin)

HEALTHY PEOPLE

Health Impact of Immunization

- Can help control the spread of infections within communities.
- Can prevent disability and death from infectious disease for individuals.
- Reduces and can possibly eliminate polio, measles, and other diseases with widespread use.
- Decreased incidence of infectious diseases (e.g., influenza, pneumonia) when more people are vaccinated against these diseases.

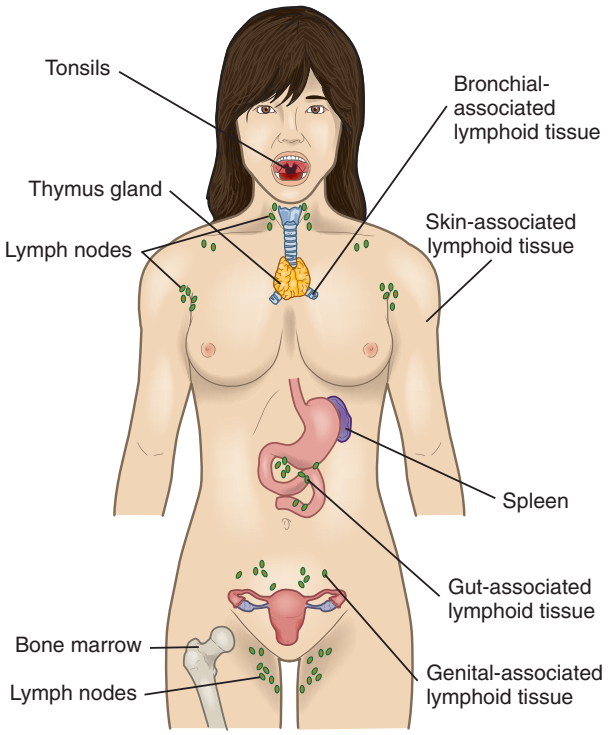

FIG. 14-1 Organs of the immune system.

throughout the body. Mononuclear phagocytes have a critical role in the immune system. They are responsible for capturing, processing, and presenting the antigen to the lymphocytes. This stimulates a humoral or cell-mediated immune response. Capturing is accomplished through phagocytosis. The macrophage-bound antigen, which is highly immunogenic, is presented to circulating T or B lymphocytes and thus triggers an immune response (Fig. 14-2).

Lymphocytes. Lymphocytes are produced in the bone marrow (Fig. 14-3). They then differentiate into B and T lymphocytes.[1]

B Lymphocytes. In the early research on *B lymphocytes* (bursa-equivalent lymphocytes) in birds, it was discovered that they mature under the influence of the bursa of Fabricius, hence the name *B cells*. However, this lymphoid organ does not exist in humans. The bursa-equivalent tissue in humans is the bone marrow. B cells differentiate into *plasma cells* when activated. Plasma cells produce antibodies (immunoglobulins) (Table 14-2).

T Lymphocytes. Cells that migrate from the bone marrow to the thymus differentiate into *T lymphocytes* (thymus-dependent cells). The thymus secretes hormones, including thymosin, that stimulate the maturation and differentiation of T lymphocytes. T cells make up 70% to 80% of the circulating lymphocytes and are primarily responsible for immunity to intracellular viruses, tumor cells, and fungi. T cells live from a few months to the life span of an individual and account for long-term immunity.

T lymphocytes can be categorized into T cytotoxic and T helper cells. Antigenic characteristics of WBCs have now been classified using monoclonal antibodies. These antigens are classified as *clusters of differentiation,* or *CD antigens*. Many types of WBCs, especially lymphocytes, are referred to by their CD designations. All mature T cells have the CD3 antigen.

T Cytotoxic Cells. T cytotoxic (CD8) cells are involved in attacking antigens on the cell membrane of foreign pathogens and releasing cytolytic substances that destroy the pathogen. These cells have antigen specificity and are sensitized by exposure to the antigen. Much like B lymphocytes, some sensitized T cells do not attack the antigen but remain as memory T cells. As in the humoral immune response, a second exposure to the antigen results in a more intense and rapid cell-mediated immune response.

T Helper Cells. T helper (CD4) cells are involved in the regulation of cell-mediated immunity and the humoral antibody response. T helper cells differentiate into subsets of cells that produce distinct types of cytokines (discussed in a later section). These subsets are called T_H1 cells and T_H2 cells. T_H1 cells stimulate phagocyte-mediated ingestion and killing of microbes, the key component of cell-mediated immunity. T_H2 cells stimulate eosinophil-mediated immunity, which is effective against parasites and is involved in allergic responses.

Natural Killer Cells. Natural killer (NK) cells are also involved in cell-mediated immunity. These cells are not T or B cells but are large lymphocytes with numerous granules in the cyto-

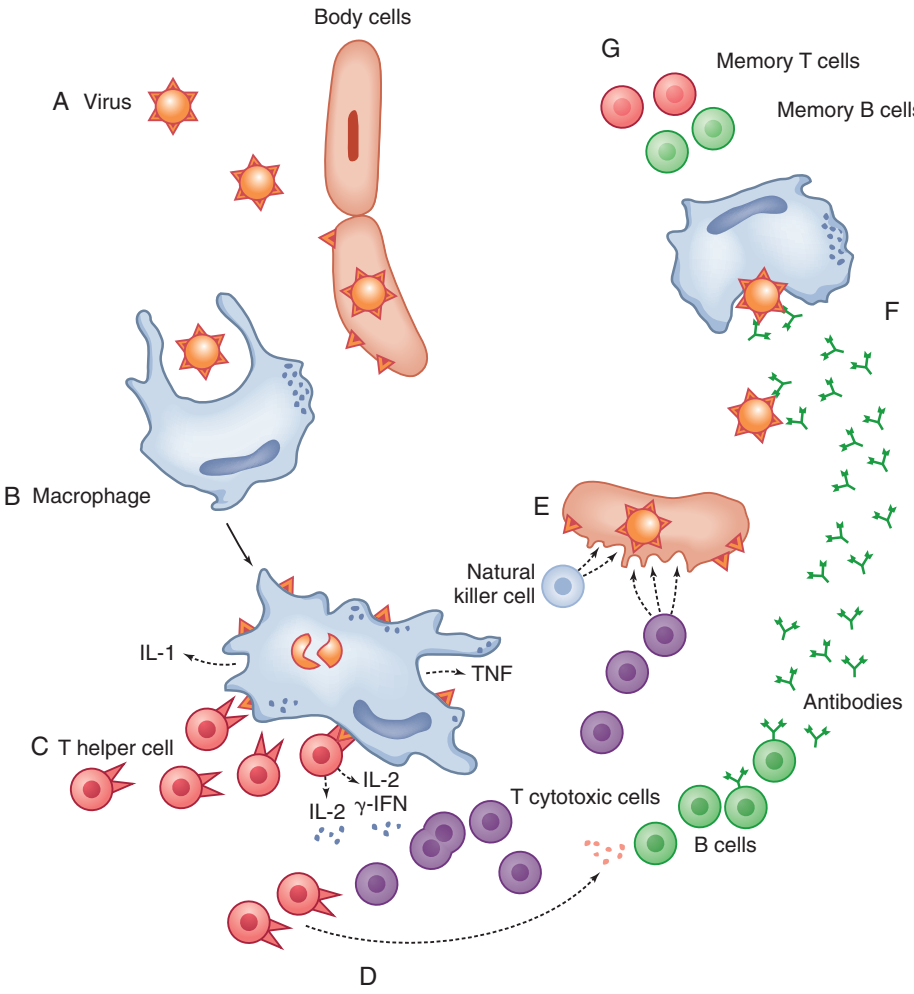

FIG. 14-2 The immune response to a virus. **A,** A virus invades the body through a break in the skin or another portal of entry. The virus must make its way inside a cell to replicate itself. **B,** A macrophage recognizes the antigens on the surface of the virus. The macrophage digests the virus and displays pieces of the virus (antigens) on its surface. **C,** A T helper cell recognizes the antigen displayed and binds to the macrophage. This binding stimulates the production of cytokines (interleukin-1 *[IL-1]* and tumor necrosis factor *[TNF]*) by the macrophage and interleukin-2 *(IL-2)* and γ-interferon *(γ-IFN)* by the T cell. These cytokines are intracellular messengers that provide communication among the cells. **D,** IL-2 instructs other T helper cells and T cytotoxic cells to proliferate (multiply). T helper cells release cytokines, causing B cells to multiply and produce antibodies. **E,** T cytotoxic cells and natural killer cells destroy infected body cells. **F,** The antibodies bind to the virus and mark it for macrophage destruction. **G,** Memory B and T cells remain behind to respond quickly if the same virus attacks again.

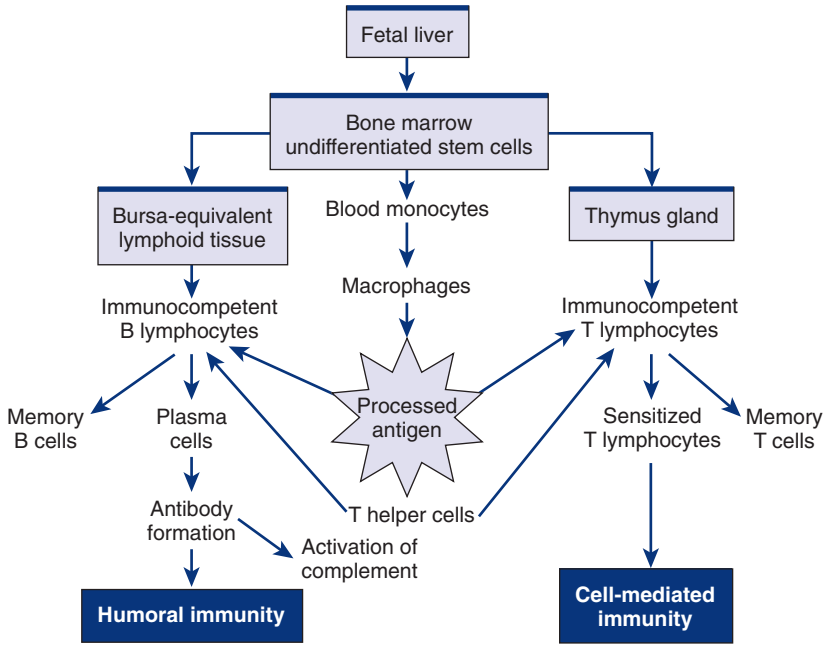

FIG. 14-3 Relationships and functions of macrophages, B lymphocytes, and T lymphocytes in an immune response.

TABLE 14-2 CHARACTERISTICS OF IMMUNOGLOBULINS

Class	Serum Concentration	Location	Characteristics
IgG	76%	Plasma, interstitial fluid	Is only immunoglobulin that crosses placenta Is responsible for secondary immune response
IgA	15%	Body secretions, including tears, saliva, breast milk, colostrum	Lines mucous membranes and protects body surfaces
IgM	8%	Plasma	Is responsible for primary immune response Forms antibodies to ABO blood antigens
IgD	1%	Plasma	Is present on lymphocyte surface Assists in the differentiation of B lymphocytes
IgE	0.002%	Plasma, interstitial fluids	Causes symptoms of allergic reactions Fixes to mast cells and basophils Assists in defense against parasitic infections

plasm. NK cells do not require prior sensitization for their generation. These cells are involved in recognition and killing of virus-infected cells, tumor cells, and transplanted grafts. The mechanism of recognition is not fully understood. NK cells have a significant role in immune surveillance for malignant cell changes.

Dendritic Cells. *Dendritic cells* make up a system of cells that are important to the immune system, especially the cell-mediated immune response. They have an atypical shape with extensive dendritic processes that form and retract. They are found in many places in the body, including the skin (where they are called Langerhans cells) and the lining of the nose, the lungs, the stomach, and the intestine. Especially in the immature state, they are found in the blood.[2]

They primarily function to capture antigens at sites of contact with the external environment (e.g., skin, mucous membranes) and then transport an antigen until it encounters a T cell with specificity for the antigen. In this role, dendritic cells can have an important function in activating the immune response.

Cytokines

The immune response involves complex interactions of T cells, B cells, monocytes, and neutrophils. These interactions depend on **cytokines** (soluble factors secreted by WBCs and a variety of other cells in the body) that act as messengers between the cell types. Cytokines instruct cells to alter their proliferation, differentiation, secretion, or activity.

Currently more than 100 different cytokines are known, and they can be classified into distinct categories. Some of these cytokines are listed in Table 14-3. In general, the interleukins act as immunomodulatory factors, colony-stimulating factors act as growth-regulating factors for hematopoietic cells, and interferons are antiviral and immunomodulatory.

The net effect of an inflammatory response is determined by a balance between proinflammatory and antiinflammatory mediators. Sometimes cytokines are classified as proinflammatory or antiinflammatory (see Table 14-3). However, it is not that clear-cut, since many other factors (e.g., target cells, environment) influence the inflammatory response to a given injury or insult.

Cytokines have a beneficial role in hematopoiesis and immune function. They can also have detrimental effects such as those seen in chronic inflammation, autoimmune diseases,

TABLE 14-3 TYPES AND FUNCTIONS OF CYTOKINES*

Type	Primary Functions
Interleukins (ILs)	
IL-1	Proinflammatory mediator. Promotes maturation and clonal expansion of B cells, enhances activity of NK cells, activates T cells, activates macrophages.
IL-2	Induces proliferation and differentiation of T cells; activation of T cells, NK cells, and macrophages. Stimulates release of other cytokines (α-IFN, TNF, IL-1, IL-6).
IL-3 (multicolony colony-stimulating factor)	Hematopoietic growth factor for hematopoietic precursor cells.
IL-4	Antiinflammatory mediator. B-cell growth factor, stimulates proliferation and differentiation of B cells. Induces differentiation into T_H2 cells. Stimulates growth of mast cells.
IL-5	B cell growth and differentiation. Promotes growth and differentiation of eosinophils.
IL-6	Proinflammatory mediator: T- and B-cell growth factor, promotes differentiation of B cells into plasma cells, stimulates antibody secretion, induces fever, synergistic effects with IL-1 and TNF.
IL-7	Promotes growth of T and B cells.
IL-8	Chemotaxis of neutrophils and T cells, stimulates superoxide and granule release.
IL-9	Enhances T cell survival, mast cell activation.
IL-10	Antiinflammatory mediator, inhibits cytokine production by T cells and NK cells, promotes B cell proliferation and antibody responses, potent suppressor of macrophage function.
Interferons (IFNs)	
α-IFN β-IFN	Inhibit viral replication, activate NK cells and macrophages, antiproliferative effects on tumor cells.
γ-IFN	Proinflammatory mediator: activates macrophages, neutrophils, and NK cells; promotes B cell differentiation. Inhibits viral replication.
Tumor Necrosis Factor (TNF)	Proinflammatory mediator; activates macrophages and granulocytes; promotes the immune and inflammatory responses; kills tumor cells; responsible for weight loss associated with chronic inflammation and cancer.
Colony-Stimulating Factors (CSFs)	
Granulocyte colony-stimulating factor (G-CSF)	Stimulates proliferation and differentiation of neutrophils, enhances functional activity of mature PMNs.
Granulocyte-macrophage colony-stimulating factor (GM-CSF)	Stimulates proliferation and differentiation of PMNs and monocytes.
Macrophage colony-stimulating factor (M-CSF)	Promotes proliferation, differentiation, and activation of monocytes and macrophages.
Erythropoietin	Stimulates erythroid progenitor cells in bone marrow to produce red blood cells.

*A more comprehensive presentation of cytokines is available at *www.rndsystems.com/molecule_group.aspx?g=704&;r=4*.
NK, Natural killer; *PMNs,* polymorphonuclear neutrophils.

and sepsis. Cytokines such as erythropoietin (see Chapter 47), colony-stimulating factors (see Table 16-14), interferons (see Table 16-13), and interleukin-2 (see Table 16-13) are used clinically to (1) stimulate hematopoiesis, (2) stimulate the bone marrow to make WBCs, and (3) treat various malignancies. In addition, inhibitors of cytokines such as soluble tumor necrosis factor receptor antagonist and interleukin-1 are used as anti-inflammatory agents. (Clinical uses of cytokines are listed in Table 14-4.)

Interferon helps the body's natural defenses attack tumors and viruses. Three types of interferon have now been identified (see Table 14-3). In addition to their direct antiviral properties, interferons have immunoregulatory functions. These include enhancement of NK cell production and activation, and inhibition of tumor cell growth.

Interferon is not directly antiviral but produces an antiviral effect in cells by reacting with them and inducing the formation of a second protein termed *antiviral protein* (Fig. 14-4). This protein mediates the antiviral action of interferon by altering the cell's protein synthesis and preventing new viruses from becoming assembled.

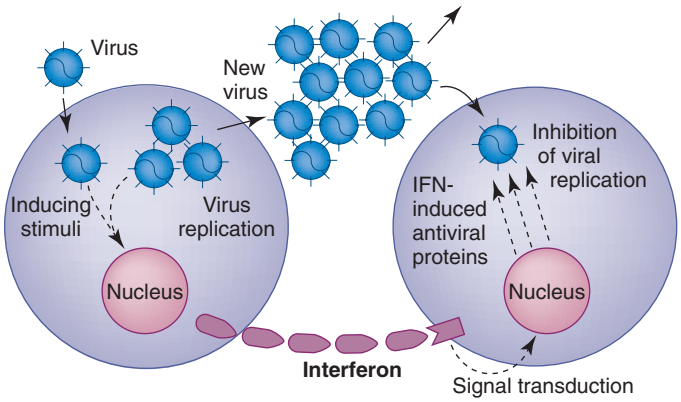

FIG. 14-4 Mechanism of action of interferon *(IFN).* When a virus attacks a cell, the cell begins to synthesize viral DNA and interferon. Interferon serves as an intercellular messenger and induces the production of antiviral proteins. Then the virus is not able to replicate in the cell.

Comparison of Humoral and Cell-Mediated Immunity

Humans need both humoral and cell-mediated immunity to remain healthy. Each type of immunity has unique properties, different methods of action, and reactions against particular antigens. Table 14-5 compares humoral and cell-mediated immunity.

Humoral Immunity. **Humoral immunity** consists of antibody-mediated immunity. The term *humoral* comes from the Greek word *humor,* which means body fluid. Since antibodies are produced by plasma cells (differentiated B cells) and found in plasma, the term *humoral immunity* is used. Production of antibodies is an essential component in a humoral immune response. Each of the five classes of immunoglobulins (Igs)—that is, IgG, IgA, IgM, IgD, and IgE—has specific characteristics (see Table 14-2).

TABLE 14-4 CLINICAL USES OF CYTOKINES

Cytokine	Clinical Uses
α-Interferon (Roferon-A, Intron A)*	Hairy cell leukemia, chronic myelogenous leukemia, malignant melanoma, renal cell carcinoma, ovarian cancer, multiple myeloma, Kaposi sarcoma, hepatitis B and C
β-Interferon (Betaseron, Avonex, Rebif)	Multiple sclerosis
Colony-Stimulating Factors	
G-CSF	
• filgrastim (Neupogen)	Chemotherapy-induced neutropenia
• pegfilgrastim (Neulasta)	
GM-CSF	
• sargramostim (Leukine)	Neutropenia, myeloid recovery after bone marrow transplantation
Soluble TNF Receptor	
etanercept (Enbrel)	Rheumatoid arthritis
Interleukin-2	
aldesleukin (Proleukin)	Metastatic renal cell carcinoma, metastatic melanoma
Interleukin 11 (platelet growth factor)	
oprelvekin (Neumega)	Prevention of thrombocytopenia after chemotherapy
Erythropoietin	
epoetin alfa (Epogen, Procrit)	Anemia of chronic cancer, anemia related to chemotherapy, anemia of chronic kidney disease
darbepoetin alfa (Aranesp)	
IL-1 Receptor Antagonist	
anakinra (Kineret)	Rheumatoid arthritis

TABLE 14-5 COMPARISON OF HUMORAL AND CELL-MEDIATED IMMUNITY

Characteristics	Humoral Immunity	Cell-Mediated Immunity
Cells involved	B lymphocytes	T lymphocytes, macrophages
Products	Antibodies	Sensitized T cells, cytokines
Memory cells	Present	Present
Protection	Bacteria Viruses (extracellular) Respiratory and GI pathogens	Fungus Viruses (intracellular) Chronic infectious agents Tumor cells
Examples	Anaphylactic shock Atopic diseases Transfusion reaction Bacterial infections	Tuberculosis Fungal infections Contact dermatitis Graft rejection Destruction of cancer cells

When a pathogen (especially bacteria) enters the body, it may encounter a B lymphocyte that is specific for antigens located on that bacterial cell wall. In addition, a monocyte or macrophage may phagocytize the bacteria and present its antigens to a B lymphocyte. The B lymphocyte recognizes the antigen because it has receptors on its cell surface specific for that antigen. When the antigen comes in contact with the cell surface receptor, the B cell becomes activated, and most B cells differentiate into plasma cells (see Fig. 14-3). The mature plasma cell secretes immunoglobulins. Some stimulated B lymphocytes remain as memory cells.

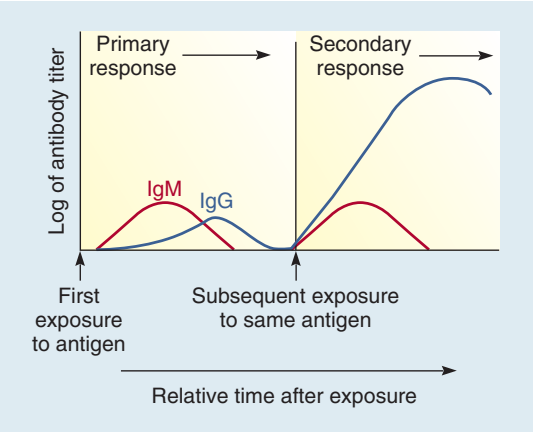

FIG. 14-5 Primary and secondary immune responses. The introduction of antigen induces a response dominated by two classes of immunoglobulins, IgM and IgG. IgM predominates in the primary response, with some IgG appearing later. After the host's immune system is primed, another challenge with the same antigen induces the secondary response, in which some IgM and large amounts of IgG are produced.

The primary immune response becomes evident 4 to 8 days after the initial exposure to the antigen (Fig. 14-5). IgM is the first type of antibody formed. Because of the large size of the IgM molecule, this immunoglobulin is confined to the intravascular space. As the immune response progresses, IgG is produced, and it can move from intravascular to extravascular spaces.

When the individual is exposed to the antigen the second time, a secondary antibody response occurs. This response occurs faster (1 to 3 days), is stronger, and lasts for a longer time than a primary response. Memory cells account for the memory of the first exposure to the antigen and the more rapid production of antibodies. IgG is the primary antibody found in a secondary immune response.

IgG crosses the placental membrane and provides the newborn with passive acquired immunity for at least 3 months. Infants may also get some passive immunity from IgA in breast milk and colostrum.

Cell-Mediated Immunity. Immune responses that are initiated through specific antigen recognition by T cells are termed **cell-mediated immunity.** Several cell types and factors are involved in cell-mediated immunity. The cell types involved include T lymphocytes, macrophages, and NK cells. Cell-mediated immunity is of primary importance in (1) immunity against pathogens that survive inside of cells, including viruses and some bacteria (e.g., mycobacteria); (2) fungal infections; (3) rejection of transplanted tissues; (4) contact hypersensitivity reactions; and (5) tumor immunity.

GERONTOLOGIC CONSIDERATIONS

EFFECTS OF AGING ON THE IMMUNE SYSTEM

With advancing age, there is a decline in the function of the immune response (Table 14-6). The primary clinical evidence of *immunosenescence* is the high incidence of malignancies in

TABLE 14-6 GERONTOLOGIC ASSESSMENT DIFFERENCES

older adults. Older people are also more susceptible to infections (e.g., influenza, pneumonia) from pathogens that they were relatively immunocompetent against earlier in life. Bacterial pneumonia is the leading cause of death from infections in older adults. The antibody response to immunizations (e.g., flu vaccine) in older adults is considerably lower than in younger adults.

The bone marrow remains relatively unaffected by increasing age. Immunoglobulin levels decrease with age and therefore lead to a suppressed humoral immune response in older adults. Thymic involution (shrinking) occurs with aging, along with decreased numbers of T cells. These changes in the thymus gland are a primary cause of immunosenescence. Both T and B cells show deficiencies in activation, transit time through the cell cycle, and subsequent differentiation. However, the most significant alterations involve T cells. As thymic output of T cells diminishes, the differentiation of T cells increases. Consequently, there is an accumulation of memory cells rather than new precursor cells responsive to previously unencountered antigens.

The delayed hypersensitivity reaction, as determined by skin testing with injected antigens, is frequently decreased or absent in older adults. This altered response reflects **anergy** (an immunodeficient condition characterized by lack of or diminished reaction to an antigen or a group of antigens).

ALTERED IMMUNE RESPONSE

Immunocompetence exists when the body's immune system can identify and inactivate or destroy foreign substances. When the immune system is incompetent or underresponsive, severe infections, immunodeficiency diseases, and malignancies may occur. When the immune system overreacts, hypersensitivity disorders such as allergies and autoimmune diseases may develop.

Hypersensitivity Reactions

Sometimes the immune response is overreactive against foreign antigens or reacts against its own tissue, resulting in tissue damage. These responses are termed **hypersensitivity reactions.** *Autoimmune diseases,* a type of hypersensitivity response, occur when the body fails to recognize self-proteins and reacts against self-antigens.

Hypersensitivity reactions can be classified according to the source of the antigen, the time sequence (immediate or delayed), or the basic immunologic mechanisms causing the injury. Four types of hypersensitivity reactions exist (Table 14-7). Types I, II, and III are immediate and are examples of humoral immunity. Type IV is a delayed hypersensitivity reaction and is related to cell-mediated immunity.

Type I: IgE-Mediated Reactions. *Anaphylactic reactions* are type I reactions that occur only in susceptible people who are highly sensitized to specific allergens. IgE antibodies, produced in response to the allergen, have a characteristic property of attaching to mast cells and basophils (Fig. 14-6; see Fig. 29-2). Within these cells are granules containing potent chemical mediators (histamine, serotonin, leukotrienes, eosinophil chemotactic factor of anaphylaxis [ECF-A], kinins, and bradyki-

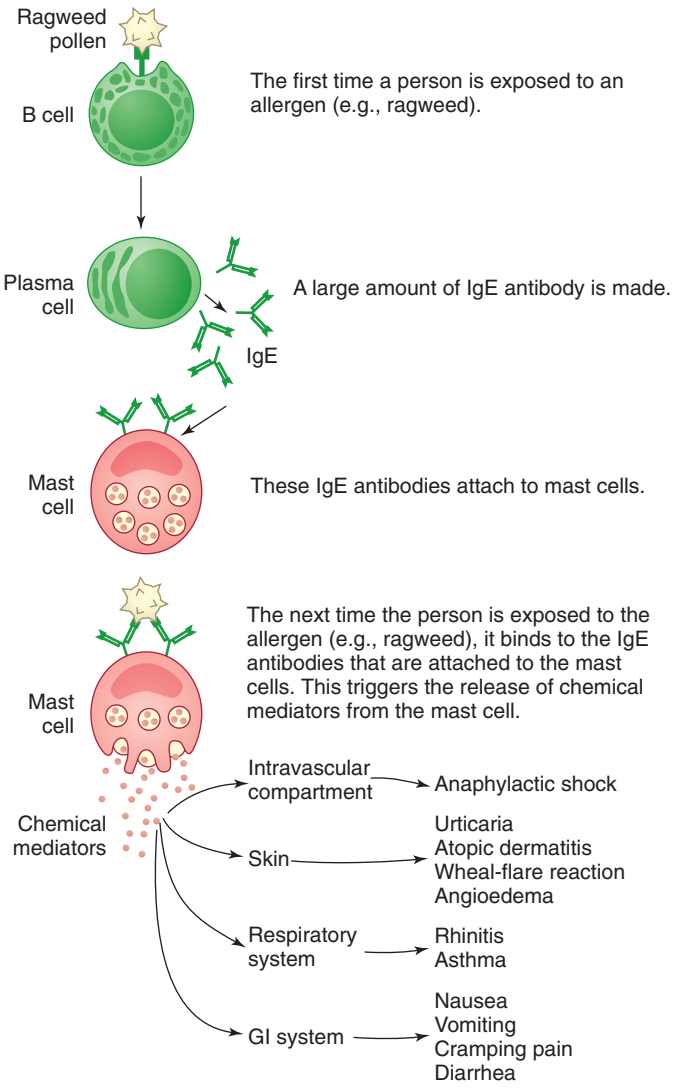

FIG. 14-6 Steps in a type I allergic reaction.

nin). (Chemical mediators of inflammation are discussed in Chapter 12 and Table 12-1.)

On the first exposure to the allergen, IgE antibodies are produced and bind to mast cells and basophils. On any subsequent exposures, the allergen links with the IgE bound to mast cells or basophils and triggers degranulation of the cells and the release of chemical mediators from the granules. In this process the mediators that are released attack target tissues, causing clinical allergy symptoms. These effects include smooth muscle contraction, increased vascular permeability, vasodilation, hypotension, increased secretion of mucus, and itching. Fortunately, the mediators are short acting and their effects are reversible. (The mediators and their effects are summarized in Table 14-8.)

A genetic predisposition to the development of allergic diseases exists. The capacity to become sensitized to an allergen, rather than the specific allergic disorder, appears to be the inherited trait. For example, a father with asthma may have a son who has allergic rhinitis.

The clinical manifestations of an anaphylactic reaction depend on whether the mediators remain local or become systemic, or whether they affect particular organs. When the

†See Chapter 12, Fig. 12-2.

mediators remain localized, a cutaneous response termed the *wheal-and-flare reaction* occurs. This reaction is characterized by a pale wheal containing edematous fluid surrounded by a red flare from the hyperemia. The reaction occurs in minutes or hours and is usually not dangerous. A classic example of a wheal-and-flare reaction is the mosquito bite. The wheal-and-flare reaction serves a diagnostic purpose as a means of demonstrating allergic reactions to specific allergens during skin tests.

Common allergic reactions include anaphylaxis and atopic reactions.

Anaphylaxis. *Anaphylaxis* can occur when mediators are released systemically (e.g., after injection of a drug, after an insect sting). The reaction occurs within minutes and can be life threatening because of bronchial constriction and subsequent airway obstruction and vascular collapse. The target organs affected are seen in Fig. 14-7. Initial symptoms include edema and itching at the site of exposure to the allergen. Shock can occur rapidly and is manifested by rapid, weak pulse; hypotension; dilated pupils; dyspnea; and possibly cyanosis. This is compounded by bronchial edema and angioedema. Death will occur if emergency treatment is not initiated. Some of the important allergens that can cause anaphylactic shock in hypersensitive people are listed in Table 14-9.

Atopic Reactions. An estimated 20% of the population is *atopic,* having an inherited tendency to become sensitive to environmental allergens. The atopic diseases that can result are allergic rhinitis, asthma, atopic dermatitis, urticaria, and angioedema.

Allergic rhinitis, or hay fever, is the most common type I hypersensitivity reaction. It may occur year-round (perennial allergic rhinitis), or it may be seasonal (seasonal allergic rhinitis). Airborne substances such as pollens, dust, and molds are the primary causes of allergic rhinitis. Perennial allergic rhinitis may be caused by dust, molds, and animal dander. Seasonal allergic rhinitis is commonly caused by pollens from trees, weeds, or grasses. The target areas affected are the conjunctiva of the eyes and the mucosa of the upper respiratory tract. Symptoms include nasal discharge; sneezing; lacrimation; mucosal swelling with airway obstruction; and pruritus around the eyes, nose, throat, and mouth. (Treatment of allergic rhinitis is discussed in Chapter 27 on p. 500.)

Many patients with *asthma* have an allergic component to their disease. These patients frequently have a history of atopic disorders (e.g., infantile eczema, allergic rhinitis, food intolerances). Inflammatory mediators produce bronchial smooth muscle constriction, excessive secretion of viscoid mucus, edema of the mucous membranes of the bronchi, and decreased

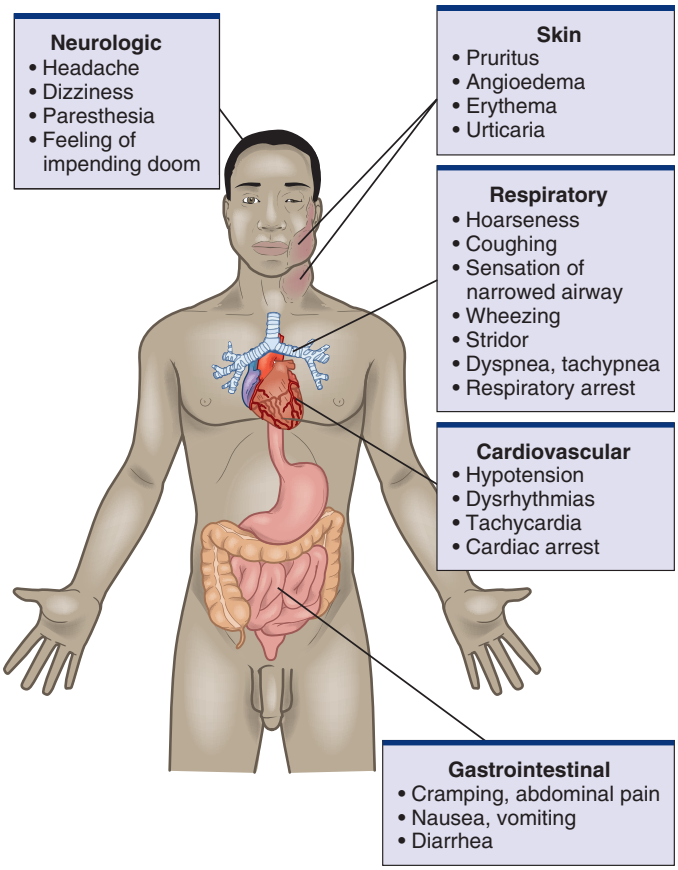

FIG. 14-7 Clinical manifestations of a systemic anaphylactic reaction.

TABLE 14-9 ALLERGENS CAUSING ANAPHYLACTIC SHOCK

Drugs
- Penicillins
- Sulfonamides
- Insulins
- Aspirin
- Tetracycline
- Local anesthetics
- Chemotherapeutic agents
- Cephalosporins
- Nonsteroidal antiinflammatory drugs

Foods
- Eggs, milk, nuts, peanuts, shellfish, fish, chocolate, strawberries

Treatment Measures
- Blood products (whole blood and components)
- Iodine-contrast media for IVP or angiogram test
- Allergenic extracts in hyposensitization therapy

Insect Venoms
- Wasps, hornets, yellow jackets, bumblebees, ants

Animal Sera
- Tetanus antitoxin
- Rabies antitoxin
- Diphtheria antitoxin
- Snake venom antitoxin

IVP, Intravenous pyelogram.

lung compliance. Because of these physiologic alterations, patients manifest dyspnea, wheezing, coughing, tightness in the chest, and thick sputum. (Pathophysiology and management of asthma are discussed in Chapter 29.)

Atopic dermatitis is a chronic, inherited skin disorder characterized by exacerbations and remissions. It is caused by several environmental allergens that are difficult to identify. Although patients with atopic dermatitis have elevated IgE levels and positive skin tests, the histopathologic features do not represent the typical, localized wheal-and-flare type I reactions.

FIG. 14-8 Atopic dermatitis of the lower leg.

The skin lesions are more generalized and involve vasodilation of blood vessels, resulting in interstitial edema with vesicle formation (Fig. 14-8). (Dermatitis is discussed in Chapter 24.)

Urticaria (hives) is a cutaneous reaction against systemic allergens occurring in atopic people. It is characterized by transient wheals (pink, raised, edematous, pruritic areas) that vary in size and shape and may occur all over the body. Urticaria develops rapidly after exposure to an allergen and may last minutes or hours. Histamine causes localized vasodilation (erythema), transudation of fluid (wheal), and flaring. Flaring is due to dilated blood vessels on the edge of the wheal. Histamine is responsible for the pruritus associated with the lesions. (Urticaria is discussed in Chapter 24.)

Angioedema is a localized cutaneous lesion similar to urticaria but involving deeper layers of the skin and the submucosa. The principal areas of involvement include the eyelids, lips, tongue, larynx, hands, feet, GI tract, and genitalia. Swelling usually begins in the face and then progresses to the airways and other parts of the body. Dilation and engorgement of the capillaries secondary to the release of histamine cause the diffuse swelling. Welts are not apparent as in urticaria. The outer skin appears normal or has a reddish hue. The lesions may burn, sting, or itch, and can cause acute abdominal pain if in the GI tract. The swelling may occur suddenly or over several hours and usually lasts for 24 hours.

Type II: Cytotoxic and Cytolytic Reactions. Cytotoxic and cytolytic reactions are type II hypersensitivity reactions involving the direct binding of IgG or IgM antibodies to an antigen on the cell surface. Antigen-antibody complexes activate the complement system, which mediates the reaction. Cellular tissue is destroyed in one of two ways: (1) activation of the complement system resulting in cytolysis or (2) enhanced phagocytosis.

Target cells frequently destroyed in type II reactions are erythrocytes, platelets, and leukocytes. Some of the antigens involved are the ABO blood group, Rh factor, and drugs. Pathophysiologic disorders characteristic of type II reactions include ABO incompatibility transfusion reaction, Rh incompatibility transfusion reaction, autoimmune and drug-related hemolytic anemias, leukopenias, thrombocytopenias, erythroblastosis fetalis (hemolytic disease of the newborn), and Goodpasture syndrome. The tissue damage usually occurs rapidly.

Hemolytic Transfusion Reactions. A classic type II reaction occurs when a recipient receives ABO-incompatible blood from a donor. Naturally acquired antibodies to antigens of the ABO blood group are in the recipient's serum but are not present on

the erythrocyte membranes (see Table 30-8). For example, a person with type A blood has anti-B antibodies, a person with type B blood has anti-A antibodies, a person with type AB blood has no antibodies, and a person with type O blood has both anti-A and anti-B antibodies.

If the recipient is transfused with incompatible blood, antibodies immediately coat the foreign erythrocytes, causing *agglutination* (clumping). The clumping of cells blocks small blood vessels in the body, uses existing clotting factors, and depletes them, leading to bleeding. Within hours, neutrophils and macrophages phagocytize the agglutinated cells. The complement system is activated (see eFig. 12-2), and cell lysis occurs, which causes the release of hemoglobin into the urine and plasma. In addition, a cytotoxic reaction causes vascular spasms in the kidney that further block the renal tubules. Acute kidney injury can result from the hemoglobinuria. (Blood transfusions are discussed in Chapter 31.)

Goodpasture Syndrome. *Goodpasture syndrome* is a disorder involving the lungs and kidneys. An antibody-mediated autoimmune reaction occurs involving the glomerular and alveolar basement membranes. The circulating antibodies combine with tissue antigen to activate the complement system, which causes deposits of IgG to form along the basement membranes of the lungs or kidneys. This reaction may result in pulmonary hemorrhage and glomerulonephritis. (Goodpasture syndrome is discussed in Chapter 46.)

Type III: Immune-Complex Reactions. Tissue damage in immune-complex reactions, which are type III reactions, occurs secondary to antigen-antibody complexes. Soluble antigens combine with immunoglobulins of the IgG and IgM classes to form complexes that are too small to be effectively removed by the mononuclear phagocyte system. Therefore the complexes deposit in tissue or small blood vessels. They cause activation of the complement system and release of chemotactic factors that lead to inflammation and destruction of the involved tissue.

Type III reactions may be local or systemic and immediate or delayed. The clinical manifestations depend on the number of complexes and the location in the body. Common sites for deposit are the kidneys, skin, joints, blood vessels, and lungs. Severe type III reactions are associated with autoimmune disorders such as systemic lupus erythematosus, acute glomerulonephritis, and rheumatoid arthritis. (Systemic lupus erythematosus and rheumatoid arthritis are discussed in Chapter 65, and acute glomerulonephritis is discussed in Chapter 46.)

Type IV: Delayed Hypersensitivity Reactions. A *delayed hypersensitivity reaction*—a type IV reaction—is also called a *cell-mediated immune response.* Although cell-mediated responses are usually protective mechanisms, tissue damage occurs in delayed hypersensitivity reactions.

The tissue damage in a type IV reaction does not occur in the presence of antibodies or complement. Rather, sensitized T lymphocytes attack antigens or release cytokines. Some of these cytokines attract macrophages into the area. The macrophages and enzymes released by them are responsible for most of the tissue destruction. In the delayed hypersensitivity reaction, it takes 24 to 48 hours for a response to occur.

Clinical examples of a delayed hypersensitivity reaction include contact dermatitis (Fig. 14-9); hypersensitivity reactions to bacterial, fungal, and viral infections; and transplant rejections. Some drug sensitivity reactions also fit this category.

Contact Dermatitis. *Allergic contact dermatitis* is an example of a delayed hypersensitivity reaction involving the skin. The reaction occurs when the skin is exposed to substances that easily penetrate the skin to combine with epidermal proteins. The substance then becomes antigenic. Over a period of 7 to 14 days, memory cells form to the antigen. On subsequent exposure to the substance, a sensitized person develops eczematous skin lesions within 48 hours. The most common potentially antigenic substances encountered are metal compounds (e.g., those containing nickel or mercury); rubber compounds; catechols present in poison ivy, poison oak, and poison sumac; cosmetics; and some dyes.

FIG. 14-9 Contact dermatitis to rubber.

In acute contact dermatitis the skin lesions appear erythematous and edematous and are covered with papules, vesicles, and bullae. The involved area is pruritic but may also burn or sting. When contact dermatitis becomes chronic, the lesions resemble atopic dermatitis because they are thickened, scaly, and lichenified. The main difference between contact dermatitis and atopic dermatitis is that contact dermatitis is localized and restricted to the area exposed to the allergens, whereas atopic dermatitis is usually widespread.

Microbial Hypersensitivity Reactions. The classic example of a microbial cell-mediated immune reaction is the body's defense against the tubercle bacillus. Tuberculosis results from invasion of lung tissue by the highly resistant tubercle bacillus. The organism itself does not directly damage the lung tissue. However, antigenic material released from the tubercle bacilli reacts with T lymphocytes, initiating a cell-mediated immune response. The resulting response causes extensive caseous necrosis of the lung.

After the initial cell-mediated reaction, memory cells persist, so subsequent contact with the tubercle bacillus or an extract of purified protein from the organism causes a delayed hypersensitivity reaction. This is the basis for the purified protein derivative (PPD) tuberculosis skin test, which is read 48 to 72 hours after the PPD is injected intradermally. (Tuberculosis is discussed in Chapter 28.)

ALLERGIC DISORDERS

Although an alteration of the immune system may be manifested in many ways, allergies, or type I hypersensitivity reactions, are seen most frequently.

Assessment

For a thorough assessment of a patient with allergies, a comprehensive patient history, physical examination, diagnostic

workup, and skin testing for allergens should be done. Obtain information from the patient about family allergies, past and present allergies, and social and environmental factors.

Family history, including information about atopic reactions in relatives, is especially important in identifying at-risk patients. Assess the specific disorder, clinical manifestations, and treatments prescribed.

Note past and present allergies. Identifying the allergens that may have triggered a reaction is essential to control allergic reactions. The time of year when an allergic reaction occurs can be a clue to a seasonal allergen. Also obtain information about any over-the-counter or prescription medications used to treat the allergies.

In addition to identifying the allergen, also obtain information about the clinical manifestations and course of allergic reaction. For women patients, assessment of symptoms during pregnancy, menstruation, or menopause may be important.

Social and environmental factors, especially the physical environment, are important. Questions about pets, trees and plants on the property, pollutants in the air, floor coverings, houseplants, and cooling and heating systems in the home and workplace can provide valuable information about allergens. In addition, a daily or weekly food diary with a description of any untoward reactions is important. Of particular interest is a screening for any reaction to medication. Finally, ask about the patient's lifestyle and stress level in connection with the appearance of allergic symptoms.

Do a comprehensive head-to-toe physical examination, with particular attention focused on the site of the allergic manifestations. Obtain a comprehensive assessment that includes subjective and objective data (Table 14-10).

TABLE 14-10 NURSING ASSESSMENT

Allergies

Subjective Data

Important Health Information

Past health history: Recurrent respiratory problems, seasonal exacerbations; unusual reactions to insect bites or stings; past and present allergies

Medications: Unusual reactions to any medications; use of over-the-counter drugs, use of medications for allergies

Functional Health Patterns

Health perception–health management: Family history of allergies; malaise

Nutritional-metabolic: Food intolerances; vomiting

Elimination: Abdominal cramps, diarrhea

Activity-exercise: Fatigue; hoarseness, cough, dyspnea

Cognitive-perceptual: Itching, burning, stinging of eyes, nose, throat, or skin; chest tightness

Role-relationship: Altered home and work environment, presence of pets

Objective Data

Integumentary

Rashes, including urticaria, wheal and flare, papules, vesicles, bullae; dryness, scaliness, scratches, irritation

Eyes, Ears, Nose, and Throat

Eyes: Conjunctivitis; lacrimation; rubbing or excessive blinking; dark circles under the eyes ("allergic shiner")

Ears: Diminished hearing; immobile or scarred tympanic membranes; recurrent ear infections

Nose: Nasal polyps; nasal voice; nose twitching; itchy nose; rhinitis; pale, boggy mucous membranes; sniffling; repeated sneezing; swollen nasal passages; recurrent, unexplained nosebleeds; crease across the bridge of nose ("allergic salute")

Throat: Continual throat clearing; swollen lips or tongue; red throat; palpable neck lymph nodes

Respiratory

Wheezing, stridor; thick sputum

Possible Diagnostic Findings

Eosinophilia of serum, sputum, or nasal and bronchial secretions; ↑ serum IgE levels; positive skin tests; abnormal chest and sinus x-rays

Diagnostic Studies

Many specialized immunologic techniques can be performed to detect abnormalities of lymphocytes, eosinophils, and immunoglobulins. A complete blood count (CBC) with WBC differential is done, with an absolute lymphocyte count and eosinophil count. Immunodeficiency is diagnosed if the lymphocyte count is below 1200/μL (1.2×10^9/L). T cell and B cell quantification is used to diagnose specific immunodeficiency syndromes. The eosinophil count is elevated in type I hypersensitivity reactions involving IgE. The serum IgE level is also generally elevated in type I hypersensitivity reactions and serves as a diagnostic indicator of atopic diseases.

Sputum and nasal and bronchial secretions may also be tested for the presence of eosinophils. If asthma is suspected, pulmonary function tests for vital capacity, forced expiratory volume, and maximum midexpiratory flow rates are helpful.

Allergy skin testing is the preferred method, but in some cases blood testing may be ordered. Allergy blood tests for IgE antibodies to specific allergens can be done using an enzyme-linked immunosorbent assay (ELISA). Allergy blood testing is recommended if a person (1) is using a drug that interferes with skin test results (e.g., antihistamines, corticosteroids) and cannot stop taking it for a few days, (2) cannot tolerate the many needle scratches required for skin testing, or (3) has a skin disorder (e.g., severe eczema, dermatitis, psoriasis).

Skin Tests. Skin testing is used to identify the specific allergens that are causing the allergy symptoms. With the use of empiric allergy medications as the treatment of choice for most allergic rhinitis, it has become common practice to omit skin testing for specific allergens in these patients. However, diagnosing an allergy to a specific antigen enables the patient to avoid an allergen and makes him or her a candidate for immunotherapy. Unfortunately, skin testing cannot be done on patients who cannot be removed from medications that suppress the histamine response or patients with food allergies.

Procedure. Skin testing may be done by three different methods: (1) a scratch or prick test, (2) an intradermal test, or (3) a patch test. The areas of the body usually used in skin testing are the arms and the back. Allergen extracts are applied to the skin in rows with a corresponding control site opposite the test site. Saline or another diluent is applied to the control site. In the *scratch test* a drop of allergen is placed on the skin, and then a pricking device is used so the allergen can enter the skin. In the *intradermal test* the allergen extract is injected under the skin, similar to a PPD test for TB. In the *patch test* an allergen is applied to a patch that is placed on the skin (see Fig. 23-10).

Results. In the scratch and intradermal tests the reaction occurs in 5 to 10 minutes. In the patch test the patches need to

be worn for 48 to 72 hours. If the person is hypersensitive to the allergen, a positive reaction will occur within minutes after insertion in the skin and may last for 8 to 12 hours. A positive reaction is manifested by a local wheal-and-flare response.

The size of the positive reaction does not always correlate with the severity of allergy symptoms. False-positive and false-negative results may occur. Negative results from skin testing do not necessarily mean the person does not have an allergic disorder, and positive results do not necessarily mean that the allergen was causing the clinical manifestations. Positive results imply that the person is sensitized to that allergen. Therefore correlating skin test results with the patient's history is important.

Precautions. A highly sensitive person is always at risk for developing an anaphylactic reaction to skin tests. Therefore a patient should never be left alone during the testing period. Sometimes skin testing is completely contraindicated and blood allergy testing is used. If a severe reaction does occur with a skin test, the extract is immediately removed and antiinflammatory topical cream is applied to the site. For intradermal testing, the arm is used so that a tourniquet can be applied during a severe reaction. A subcutaneous injection of epinephrine may also be necessary.

Collaborative Care

After an allergic disorder is diagnosed, treatment is aimed at reducing exposure to the offending allergen, treating the symptoms, and, if necessary, desensitizing the person through immunotherapy.

Anaphylaxis. Anaphylactic reactions occur suddenly in hypersensitive patients after exposure to the offending allergen. They may occur after parenteral injection of drugs (especially antibiotics) or blood products, and after insect stings. The cardinal principle in management is speed in (1) recognition of signs and symptoms of an anaphylactic reaction, (2) maintenance of a patent airway, (3) prevention of spread of the allergen by using a tourniquet, (4) administration of drugs, and (5) treatment for shock. Table 14-11 summarizes the emergency treatment of anaphylactic shock.

Severe cases of anaphylaxis may result in hypovolemic shock because of the loss of intravascular fluid into interstitial spaces that occurs secondary to increased capillary permeability. Peripheral vasoconstriction and stimulation of the sympathetic nervous system occur to compensate for the fluid shift. However, unless shock is treated early, the body will no longer be able to compensate, and irreversible tissue damage will occur, leading to death. (Hypovolemic shock is discussed in Chapter 67.)

All health care workers must be prepared for the rare but life-threatening anaphylactic reaction, which requires immediate medical and nursing interventions. It is extremely important to list all of a patient's allergies on the chart, the nursing care plan, and the medication record.

Chronic Allergies. Most allergic reactions are chronic and are characterized by remissions and exacerbations of symptoms. Treatment focuses on identification and control of allergens, relief of symptoms through drug therapy, and hyposensitization of a patient to an offending allergen.

Allergen Recognition and Control. You play an important role in helping the patient make lifestyle adjustments so that there is minimal exposure to offending allergens. Reinforce that, even with drug therapy and immunotherapy, the patient will never be totally desensitized or completely symptom free. Help the patient initiate various preventive measures to control the allergic symptoms.

Of primary importance is the need to identify the offending allergen. Sometimes this is done through skin testing. In the case of food allergies an elimination diet is sometimes valuable. If an allergic reaction occurs, all foods eaten shortly before the reaction should be eliminated and gradually reintroduced one at a time until the offending food is detected.

Many allergic reactions, especially asthma and urticaria, may be aggravated by fatigue and emotional stress. Assist the patient in planning a stress management program. Relaxation techniques can be practiced when the patient comes for frequent immunotherapy treatments.

Sometimes control of allergic symptoms requires environmental control, including changing an occupation, moving to a different climate, or giving up a favorite pet. In the case of airborne allergens, sleeping in an air-conditioned room, damp dusting daily, covering mattresses and pillows with hypoallergenic covers, and wearing a mask outdoors may be helpful.

If the allergen is a drug, instruct the patient to avoid the drug. The patient also has the responsibility to make his or her allergies well known to all health care providers. The patient should wear a Medic Alert bracelet listing the particular drug allergy and have the offending drug listed on all medical and dental records.

TABLE 14-11 EMERGENCY MANAGEMENT

Anaphylactic Shock

Etiology

- Injection of, inhalation of, ingestion of, or topical exposure to substance that produces profound allergic response (See Table 14-9 for more complete listing.)

Assessment Findings

See Fig. 14-7.

Interventions

Initial

- Ensure patent airway.
- Administer high-flow O_2 via non-rebreather mask.
- Remove insect stinger if present.
- Establish IV access.
- epinephrine 1:1000, 0.01 mL/kg (0.3-0.5 mL) IM into midanterior lateral thigh; repeat every 5-15 min.*
- Nebulized albuterol (Proventil).
- Diphenhydramine (Benadryl) IM or IV.
- Corticosteroids: methylprednisolone (Solu-Medrol) IV.

Hypotension

- Place recumbent and elevate legs.
- epinephrine 1:10,000, 0.1 mL/kg IV every 2-5 min.
- Maintain blood pressure with fluids, volume expanders, vasopressors (e.g., dopamine [Intropin]).

Ongoing Monitoring

- Monitor vital signs, respiratory effort, O_2 saturation, level of consciousness, and cardiac rhythm.
- Anticipate intubation with severe respiratory distress.
- Anticipate cricothyrotomy or tracheostomy with severe laryngeal edema.

*Patients receiving β-blockers may be resistant to treatment with epinephrine and can develop refractory hypotension and bradycardia. Glucagon should be administered in this setting because it has inotropic and chronotropic effects that are not mediated through β-receptors.

For a patient allergic to insect stings, commercial bee-sting kits containing preinjectable epinephrine and a tourniquet are available. Instruct the patient and the family about the technique of applying the tourniquet and self-injecting the subcutaneous epinephrine. This patient also should wear a Medic Alert bracelet and carry a bee-sting kit whenever going outdoors.

Drug Therapy. The major categories of drugs used for symptomatic relief of chronic allergic disorders include antihistamines, sympathomimetic/decongestant drugs, corticosteroids, antipruritic drugs, and mast cell–stabilizing drugs. Many of these drugs can be obtained over the counter and are often misused by patients.

Antihistamines. Antihistamines are the best drugs for treatment of allergic rhinitis and urticaria (see Chapter 27, Table 27-2). They are less effective for severe allergic reactions. They act by competing with histamine for H_1-receptor sites and thus blocking the effect of histamine. Best results are achieved if they are taken as soon as allergy symptoms appear. Antihistamines can be used effectively to treat edema and pruritus but are relatively ineffective in preventing bronchoconstriction. With seasonal rhinitis, antihistamines should be taken during peak pollen seasons. (Antihistamines are discussed in Chapter 27.)

Sympathomimetic/Decongestant Drugs. The major sympathomimetic drug is epinephrine (Adrenalin), which is the drug of choice to treat an anaphylactic reaction. Epinephrine is produced by the adrenal medulla and stimulates α- and β-adrenergic receptors. Stimulation of the α-adrenergic receptors causes vasoconstriction of peripheral blood vessels. β-Receptor stimulation relaxes bronchial smooth muscles. Epinephrine also acts directly on mast cells to stabilize them against further degranulation. The action of epinephrine lasts only a few minutes. For the treatment of anaphylaxis, the drug must be given parenterally (intramuscular [IM], IV).

Several specific, minor sympathomimetic drugs differ from epinephrine because they can be taken orally or nasally and last for several hours. Included in this category are phenylephrine (Neo-Synephrine) and pseudoephedrine (Sudafed). The minor sympathomimetic drugs are used primarily to treat allergic rhinitis.

Corticosteroids. Nasal corticosteroid sprays are effective in relieving the symptoms of allergic rhinitis (see Chapter 27 and Table 27-2). Occasionally patients have such severe manifestations of allergies that they are truly incapacitated. In these situations a brief course of oral corticosteroids can be used.

Antipruritic Drugs. Topically applied antipruritic drugs are most effective when the skin is not broken. These drugs protect the skin and provide relief from itching. Common over-the-counter drugs include calamine lotion, coal tar solutions, and camphor. Menthol and phenol may be added to other lotions to produce an antipruritic effect. Some more potent drugs that require a prescription include methdilazine (Tacaryl) and trimeprazine (Temaril). These drugs should be used with great caution because of the associated risk of agranulocytosis.

Mast Cell–Stabilizing Drug. Cromolyn (Intal, NasalCrom) is a mast cell–stabilizing agent that inhibits the release of histamines, leukotrienes, and other agents from the mast cell after antigen-IgE interaction. It is available as an inhalant nebulizer solution or a nasal spray. Cromolyn is used in the management of allergic rhinitis (see Chapter 27).

Leukotriene Receptor Antagonists. Leukotriene receptor antagonists (LTRAs) block leukotriene, one of the major mediators of the allergic inflammatory process (see Table 27-2). These medications can be taken orally. They may be used in the treatment of allergic rhinitis and asthma.

Immunotherapy. Immunotherapy is the recommended treatment for control of allergic symptoms when the allergen cannot be avoided and drug therapy is not effective.[3] Relatively few patients with allergies have symptoms so intolerable that they require allergy immunotherapy. (In individuals with anaphylactic reactions to insect venom, immunotherapy is definitely indicated.)

Immunotherapy involves administration of small titers of an allergen extract in increasing strengths until hyposensitivity to the specific allergen is achieved. For best results, teach the patient to avoid the offending allergen whenever possible because complete desensitization is impossible. Unfortunately, not all allergy-related conditions respond to immunotherapy. Food allergies cannot be safely treated with this therapy, and eczema may worsen with immunotherapy.

Mechanism of Action. The IgE level is elevated in atopic individuals. When IgE combines with an allergen in a hypersensitive person, a reaction occurs, releasing histamine in various body tissues. Allergens more readily combine with IgG than with other immunoglobulins. Therefore immunotherapy involves injecting allergen extracts that will stimulate increased IgG levels. The binding of IgG to allergen-reactive sites interferes with allergen binding to mast cell–bound IgE, preventing mast cell degranulation, and thus reduces the number of reactions that cause tissue damage. The goal of long-term immunotherapy is to keep "blocking" IgG levels high. In addition, allergen-specific T suppressor cells develop in individuals receiving immunotherapy.

Method of Administration. The allergens included in immunotherapy are chosen based on the results of skin testing with a panel of allergens.

Subcutaneous Immunotherapy. *Subcutaneous immunotherapy* involves the subcutaneous injection of titrated amounts of allergen extracts biweekly or weekly. The dose is small at first and is increased slowly until a maintenance dosage is reached. Generally it takes 1 to 2 years of immunotherapy to reach the maximal therapeutic effect. Therapy may be continued for about 5 years. After that, discontinuing therapy is considered. In many patients a decrease in symptoms is sustained after the treatment is discontinued. For patients with severe allergies or sensitivity to insect stings, maintenance therapy is continued indefinitely. Best results are achieved when immunotherapy is administered throughout the year.

Sublingual Immunotherapy. *Sublingual immunotherapy* involves allergen extracts taken under the tongue. This method of immunotherapy has a lower risk of severe adverse reaction than the traditional subcutaneous administration. Today in Europe, sublingual immunotherapy accounts for 40% of allergy treatment. In the United States, although some allergists are using sublingual immunotherapy, it is considered an investigational therapy. Most insurance plans do not cover sublingual immunotherapy. It is considered a U.S. Food and Drug Administration (FDA) "off-label" use. An advantage of this form of immunotherapy is that patients can do it at home.[3]

NURSING MANAGEMENT IMMUNOTHERAPY

You will often be the person responsible for administering subcutaneous immunotherapy. Always anticipate adverse reac-

tions, especially when using a new-strength dose, after a previous reaction, or after a missed dose. Early manifestations of a systemic reaction include pruritus, urticaria, sneezing, laryngeal edema, and hypotension. Emergency measures for anaphylactic shock should be initiated immediately. Describe a local reaction according to the degree of redness and swelling at the injection site. If the area is greater than the size of a quarter in an adult, report the reaction to the health care provider so that the allergen dosage may be decreased.

Immunotherapy always carries the risk of a severe anaphylactic reaction. Therefore a health care provider, emergency equipment, and essential drugs should be available whenever injections are given.

Record keeping must be accurate and can be invaluable in preventing an adverse reaction to the allergen extract. Before giving an injection, check the patient's name against the name on the vial. Next, determine the vial strength, amount of last dose, date of last dose, and any reaction information.

Always administer the allergen extract in an extremity away from a joint so that a tourniquet can be applied for a severe reaction. Rotate the site for each injection. Aspirate for blood before giving an injection to ensure that the allergen extract is not injected into a blood vessel. An injection directly into the bloodstream can potentiate an anaphylactic reaction. After giving the injection, carefully observe the patient for 20 minutes, since systemic reactions are most likely to occur immediately. However, warn the patient that a delayed reaction can occur as long as 24 hours later.

Latex Allergies

Allergies to latex products have become an increasing problem, affecting both patients and health care professionals. The increase in allergic reactions has coincided with the sharp increase in glove use. It is estimated that 5% to 18% of health care workers regularly exposed to latex are sensitized. The more frequent and prolonged the exposure to latex, the greater the likelihood of developing a latex allergy.[4]

In addition to gloves, many latex-containing products are used in health care, such as blood pressure cuffs, stethoscopes, tourniquets, IV tubing, syringes, electrode pads, O_2 masks, tracheal tubes, colostomy and ileostomy pouches, urinary catheters, anesthetic masks, and adhesive tape. Latex proteins can become aerosolized through powder on gloves and can result in serious reactions when inhaled by sensitized individuals. It is recommended that all health care facilities use powder-free gloves to avoid respiratory exposure to latex proteins.

Types of Latex Allergies. Two types of latex allergies can occur: type IV allergic contact dermatitis and type I allergic reactions. *Type IV contact dermatitis* is caused by the chemicals used in the manufacturing process of latex gloves. It is a delayed reaction that occurs within 6 to 48 hours. Typically the person first has dryness, pruritus, fissuring, and cracking of the skin, followed by redness, swelling, and crusting at 24 to 48 hours. Chronic exposure can lead to lichenification, scaling, and hyperpigmentation. The dermatitis may extend beyond the area of physical contact with the allergen.

A *type I allergic reaction* is a response to the natural rubber latex proteins and occurs within minutes of contact with the proteins. The manifestations of these allergic reactions can vary from skin redness, urticaria, rhinitis, conjunctivitis, or asthma to full-blown anaphylactic shock. Systemic reactions to latex may result from exposure to latex protein via various routes, including the skin, mucous membranes, inhalation, and blood.[5]

Latex-Food Syndrome. Because some proteins in rubber are similar to food proteins, some foods may cause an allergic reaction in people who are allergic to latex. This is called *latex-food syndrome*. The most common of these foods are banana, avocado, chestnut, kiwi, tomato, water chestnut, guava, hazelnut, potato, peach, grape, and apricot. In people with latex allergy, most have a positive allergy test to at least one related food.

NURSING AND COLLABORATIVE MANAGEMENT
LATEX ALLERGIES

Identifying patients and health care workers sensitive to latex is crucial to prevent adverse reactions. Obtain a thorough health history and history of any allergies, especially for patients with any complaints of latex contact symptoms. Not all latex-sensitive individuals can be identified, even with a careful and thorough history. The greatest risk factor is long-term multiple exposures to latex products (e.g., health care personnel, individuals who have had multiple surgeries, rubber industry workers). Additional risk factors include a patient history of hay fever, asthma, and allergies to certain foods (listed earlier).

Use latex precaution protocols for those patients identified as having a positive latex allergy test or a history of signs and symptoms related to latex exposure.[6] Many health care facilities have created latex-free product carts that can be used for patients with latex allergies. The National Institute for Occupational Safety and Health (NIOSH) has published recommendations for preventing allergic reactions to latex in the workplace (Table 14-12).

Because of the potential for severe symptoms of food allergy, teach patients to avoid those foods. Other recommendations for people with latex and food allergies include wearing a Medic Alert bracelet or necklace and carrying an injectable epinephrine pen.

Multiple Chemical Sensitivity

Multiple chemical sensitivity (MCS) is a chronic condition characterized by symptoms that the affected person attributes to low-level chemical exposure. Commonly accused substances

TABLE 14-12 GUIDELINES FOR PREVENTING ALLERGIC LATEX REACTIONS

- Use nonlatex gloves for activities that are not likely to involve contact with infectious materials (e.g., food preparation, housekeeping).
- Use powder-free gloves with reduced protein content.
- Do not use oil-based hand creams or lotions when wearing gloves.
- After removing gloves, wash hands with mild soap and dry thoroughly.
- Frequently clean work areas that are contaminated with latex-containing dust.
- Know the symptoms of latex allergy, including skin rash; hives; flushing; itching; nasal, eye, or sinus symptoms; asthma; and shock.
- If symptoms of latex allergy develop, avoid direct contact with latex gloves and products.
- Wear a Medic Alert bracelet and carry an epinephrine pen (e.g., EpiPen).

Source: National Institute for Occupational Safety and Health (NIOSH) *(www.cdc.gov/niosh)*.

include smoke, pesticides, plastics, synthetic fabrics, scented products, petroleum products, and paint fumes. Women between the ages of 30 and 50 are more likely to develop the symptoms. Symptoms have also been reported among military personnel, particularly Gulf War veterans. MCS is a controversial diagnosis and is not recognized as a chemical-caused illness by the American Medical Association or other authorities.[7,8]

The symptoms that people report are wide ranging and not specific. They include headache, fatigue, dizziness, nausea, congestion, itching, sneezing, sore throat, chest pain, breathing problems, muscle pain or stiffness, skin rash, diarrhea, bloating, gas, confusion, difficulty concentrating, memory problems, and mood changes. These symptoms are usually subjective, and there is no evidence of a pathologic condition or physiologic dysfunction.

Diagnosis is usually made based on a patient's health history. There is no established test to diagnose MCS. The most effective treatment for MCS is to avoid the chemicals that may trigger the symptoms and create a chemical-free and odor-free home and workplace. Antidepressants, including selective serotonin reuptake inhibitors (SSRIs) (e.g., citalopram [Celexa]), have been used for treatment. Drugs for anxiety and sleep have also been used.

TABLE 14-13 EXAMPLES OF AUTOIMMUNE DISEASES*

Systemic Diseases
- Mixed connective tissue disease
- Progressive systemic sclerosis (scleroderma)
- Rheumatoid arthritis
- Systemic lupus erythematosus

Organ-Specific Diseases

Blood
- Autoimmune hemolytic anemia
- Immune thrombocytopenic purpura
- Hemochromatosis

Central Nervous System
- Guillain-Barré syndrome
- Multiple sclerosis

Muscle
- Myasthenia gravis

Heart
- Rheumatic fever

Endocrine System
- Addison's disease
- Graves' disease
- Hypothyroidism
- Thyroiditis
- Type 1 diabetes mellitus

Gastrointestinal System
- Celiac disease
- Pernicious anemia
- Ulcerative colitis

Kidney
- Glomerulonephritis
- Goodpasture syndrome

Liver
- Autoimmune hepatitis
- Primary biliary cirrhosis

Eye
- Uveitis

* These diseases are discussed in various chapters throughout the book.

AUTOIMMUNITY

Autoimmunity is an immune response against self in which the immune system no longer differentiates self from nonself. For some unknown reason, immune cells that are normally unresponsive (tolerant to self-antigens) are activated. In autoimmunity, autoantibodies and autosensitized T cells cause pathophysiologic tissue damage.

The cause of autoimmune diseases is still unknown. Age is thought to play some role because the number of circulating autoantibodies increases in people over age 50. However, the principal factors in the development of autoimmunity are (1) the inheritance of susceptibility genes, which may contribute to the failure of self-tolerance; and (2) initiation of autoreactivity by triggers, such as infections, which may activate self-reactive lymphocytes.

Autoimmune diseases tend to cluster, so that a given person may have more than one autoimmune disease (e.g., rheumatoid arthritis, Addison's disease), or the same or related autoimmune diseases may be found in other members of the same family. This observation has led to the concept of genetic predisposition to autoimmune disease. Most of the genetic research in this area correlates certain human leukocyte antigen (HLA) types with an autoimmune condition. (HLAs and disease association are discussed later in this chapter on p. 219.)

Even in a genetically predisposed person, some trigger is required for the initiation of autoreactivity. This may include infectious agents such as a virus. Viral infections can cause an alteration of cells or tissues that are not normally antigenic. The virally induced changes can make the cells or tissues antigenic. Viruses may be involved in the development of diseases such as type 1 diabetes mellitus.[9] Rheumatic fever and rheumatic heart disease are autoimmune responses triggered by streptococcal infection and mediated by antibodies against group A β-hemolytic streptococci that cross-react with heart muscles and valves and synovial membranes.

Drugs can also be precipitating factors in autoimmune disease. Hemolytic anemia can result from methyldopa (Aldomet) administration. Procainamide (Pronestyl) can induce the formation of antinuclear antibodies and cause a lupus-like syndrome.

Gender and hormones also have a role in autoimmune disease. More women than men have autoimmune disease. During pregnancy, many autoimmune diseases get better. After delivery, the woman with an autoimmune disease frequently has an exacerbation.

Autoimmune Diseases

Generally, autoimmune diseases are grouped according to organ-specific and systemic diseases (Table 14-13). Systemic lupus erythematosus (SLE) is a classic example of a systemic autoimmune disease characterized by damage to multiple organs. It occurs most frequently in women ages 20 to 40 years. The cause is unknown, but there appears to be a loss of self-tolerance for the body's own DNA antigens.

In SLE, tissue injury appears to be the result of the formation of antinuclear antibodies. For some reason (possibly a viral infection), the cell membrane is damaged and deoxyribonucleic acid (DNA) is released into the systemic circulation, where it is viewed as nonself. This DNA is normally sequestered inside the nucleus of cells. On release into the circulation, the DNA antigen reacts with an antibody. Some antibodies are involved in immune complex formation, and others may cause damage directly. Once the complexes are deposited, the complement system is activated and further damages the tissue, especially the renal glomerulus. (SLE is discussed in Chapter 65.)

Apheresis

Apheresis has been effectively used to treat autoimmune diseases and other diseases and disorders. *Apheresis* is a procedure to separate components of the blood followed by the removal of one or more of these components. Compound words are often used to describe any particular apheresis procedure, depending on the blood components being collected. *Plateletpheresis* is the removal of platelets, usually for collection from normal individuals to infuse into patients with low platelet

counts (e.g., patients taking chemotherapy who develop thrombocytopenia). *Leukocytapheresis* is a general term indicating the removal of WBCs and is used in chronic myelogenous leukemia to remove high numbers of leukemic cells.

Apheresis is also used in peripheral stem cell transplantation to collect stem cells from peripheral blood. These stem cells can then be used to repopulate a person's bone marrow after high-dose chemotherapy (see section on hematopoietic stem cell transplants in Chapter 16).

Plasmapheresis. *Plasmapheresis* is the removal of plasma containing components causing or thought to cause disease. It can also be used to obtain plasma from healthy donors to administer to patients as replacement therapy.

When plasma is removed, it is replaced by substitute fluids such as saline, fresh-frozen plasma, or albumin. Thus the term *plasma exchange* more accurately describes this procedure.

Plasmapheresis has been used to treat autoimmune diseases such as SLE, glomerulonephritis, Goodpasture syndrome, myasthenia gravis, thrombocytopenic purpura, rheumatoid arthritis, and Guillain-Barré syndrome. Many disorders for which plasmapheresis is used are characterized by circulating autoantibodies (usually of the IgG class) and antigen-antibody complexes. The rationale for performing therapeutic plasmapheresis in autoimmune disorders is to remove pathologic substances present in plasma. Immunosuppressive therapy has been used to prevent recovery of IgG production, and plasmapheresis has been used to prevent antibody rebound.

In addition to removing antibodies and antigen-antibody complexes, plasmapheresis may also remove inflammatory mediators (e.g., complement) that are responsible for tissue damage. In the treatment of SLE, plasmapheresis is usually reserved for the patient having an acute attack who is unresponsive to conventional therapy.

Plasmapheresis involves the removal of whole blood through an IV device, and then the blood circulates through the apheresis machine. Inside the machine the blood is divided into plasma and its cellular components by centrifugation or membrane filtration. The plasma is generally replaced with normal saline, lactated Ringer's solution, fresh-frozen plasma, plasma protein fractions, or albumin. When blood is manually removed, only 500 mL can be taken at one time. However, with the use of apheresis procedures, more than 4 L of plasma can be pheresed in 2 to 3 hours.

As with administration of other blood products, be aware of side effects associated with plasmapheresis. The most common complications are hypotension and citrate toxicity. Hypotension is usually the result of a vasovagal reaction or transient volume changes. Citrate is used as an anticoagulant and may cause hypocalcemia, which may manifest as headache, paresthesias, and dizziness.

IMMUNODEFICIENCY DISORDERS

When the immune system does not adequately protect the body, **immunodeficiency** exists. Immunodeficiency disorders involve an impairment of one or more immune mechanisms, which include (1) phagocytosis, (2) humoral response, (3) cell-mediated response, (4) complement, and (5) a combined humoral and cell-mediated deficiency. Immunodeficiency disorders are *primary* if the immune cells are improperly developed or absent and *secondary* if the deficiency is caused by illnesses or treatment. Primary immunodeficiency disorders are rare and often serious, whereas secondary disorders are more common and less severe.

Primary Immunodeficiency Disorders

The basic categories of primary immunodeficiency disorders are (1) phagocytic defects, (2) B cell deficiency, (3) T cell deficiency, and (4) a combined B cell and T cell deficiency (Table 14-14).

Secondary Immunodeficiency Disorders

Some of the important factors that may cause secondary immunodeficiency disorders are listed in Table 14-15. Drug-induced immunosuppression is the most common. Immunosuppressive therapy is prescribed for patients to treat autoimmune disorders and to prevent transplant rejection. In addition, immunosuppression is a serious side effect of drugs used in cancer chemotherapy. Generalized leukopenia often results, leading to a decreased humoral and cell-mediated response. Therefore secondary infections are common in immunosuppressed patients.

TABLE 14-14 PRIMARY IMMUNODEFICIENCY DISORDERS

Disorder	Affected Cells	Genetic Basis
Chronic granulomatous disease	PMNs, monocytes	X-linked
Job syndrome	PMNs, monocytes	—
Bruton's X-linked agammaglobulinemia	B	X-linked
Common variable hypogammaglobulinemia	B	—
Selective IgA, IgM, or IgG deficiency	B	Some X-linked
DiGeorge syndrome (thymic hypoplasia)	T	—
Severe combined immunodeficiency disease	Stem, B, T	X-linked or autosomal recessive
Ataxia-telangiectasia	B, T	Autosomal recessive
Wiskott-Aldrich syndrome	B, T	X-linked
Graft-versus-host disease	B, T	—

PMNs, Polymorphonuclear neutrophils.

TABLE 14-15 CAUSES OF SECONDARY IMMUNODEFICIENCY

Drug-Induced Immunodeficiency
- Chemotherapy drugs
- Corticosteroids

Age
- Infants
- Older adults

Malnutrition
- Dietary deficiency
- Cachexia

Therapies
- Radiation
- Surgery
- Anesthesia

Diseases or Disorders
- Acquired immunodeficiency syndrome (AIDS)
- Cirrhosis
- Chronic kidney disease
- Diabetes mellitus
- Hodgkin's lymphoma
- Malignancies
- Systemic lupus erythematosus
- Burns
- Trauma
- Severe infection

Stress
- Chronic stress
- Trauma (physical or emotional)

Malnutrition alters cell-mediated immune responses. When protein is deficient over a prolonged period, the thymus gland atrophies and lymphoid tissue decreases. In addition, an increased susceptibility to infections always exists.

Hodgkin's lymphoma greatly impairs the cell-mediated immune response, and patients may die from severe viral or fungal infections. (Hodgkin's lymphoma is discussed in Chapter 31.) Viruses, especially rubella, may cause immunodeficiency by direct cytotoxic damage to lymphoid cells. Systemic infections can place such a demand on the immune system that resistance to a secondary or subsequent infection is impaired.

Radiation can destroy lymphocytes either directly or through depletion of stem cells. As the radiation dose is increased, more bone marrow atrophies, leading to severe pancytopenia and suppression of immune function. Splenectomy in children is especially dangerous and may lead to septicemia simply from respiratory tract infections.

Stress may alter the immune response. This response involves interrelationships among the nervous, endocrine, and immune systems (see Chapter 7).

HUMAN LEUKOCYTE ANTIGEN SYSTEM

The antigens responsible for rejection of genetically unlike tissues are called the *major histocompatibility antigens*. These antigens are products of histocompatibility genes. In humans they are called the **human leukocyte antigen (HLA)** system. The genes for the HLA antigens are linked and occur together on the sixth chromosome. HLAs are present on all nucleated cells and platelets. The HLA system is primarily used in matching organs and tissues for transplantation.

An important characteristic of HLA genes is that they are highly polymorphic (variable). Each HLA locus can have many different possible alleles, and thus many combinations exist. Each person has two alleles for each locus, one inherited from each parent. Both alleles of a locus are expressed independently (i.e., they are codominant). The proteins encoded by certain genes are known as *antigens*. The entire set of A, B, C, D, and DR genes (the HLA genes) located on one chromosome is termed a *haplotype*. A complete set is inherited as a unit (haplotype). One haplotype is inherited from each parent (Fig. 14-10). This means that a person has HLA genes that are one-half identical to those of each parent. The HLA genes have a 25% chance of being identical to the HLA genes of a sibling.

In organ transplantation A, B, and DR are primarily used for compatibility matching. The specific allele at each locus is identified by a number. For example, a person could have an HLA of A2, A6, B7, B27, DR4, and DR7. Currently more than 8000 HLA alleles have been identified for the various HLA genes.[10]

Human Leukocyte Antigen and Disease Associations

The early interest in HLAs was stimulated by the role of HLAs in matching donors and recipients of organ transplants. Since that time the interest in the association between HLAs and disease has grown.

A number of diseases show significant associations with specific HLA alleles. People who have these alleles are much more likely to develop the associated disease than those who do not have the allele. However, the possession of a particular HLA allele does not mean that the person will necessarily develop the associated disease—only that the relative risk is greater than in the general population.

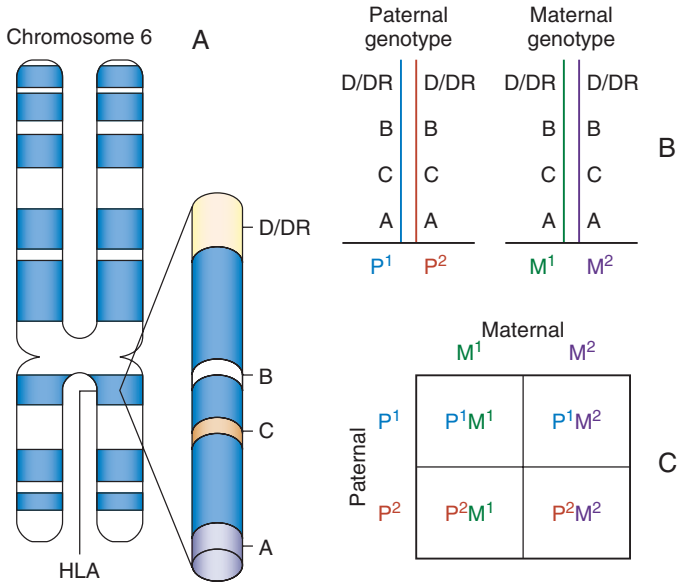

FIG. 14-10 Patterns of human leukocyte antigen *(HLA)* inheritance. **A,** HLA genes are located on chromosome 6. **B,** The two haplotypes of the father are labeled P^1 and P^2, and the haplotypes of the mother are labeled M^1 and M^2. Each child inherits two haplotypes, one from each parent. **C,** Therefore only four combinations—P^1M^1, P^1M^2, P^2M^1, and P^2M^2—are possible, and 25% of the offspring will have identical HLA haplotypes.

Most of the HLA-associated diseases are classified as autoimmune disorders. Examples of HLA types and disease associations include (1) HLA-B27 and ankylosing spondylitis, (2) HLA-DR2 and HLA-DR3 and SLE, (3) HLA-DR3 and HLA-DR4 and diabetes mellitus, and (5) HLA-DR2 and narcolepsy.

The discovery of HLA associations with certain diseases is a major breakthrough in understanding the genetic bases of these diseases. It is now known that at least part of the genetic bases of HLA-associated diseases lies in the HLA region, but the actual mechanisms involved in these associations are still unknown. However, most individuals who inherit a specific HLA type (e.g., HLA-DR3) that is associated with a disease will never develop that disease.

Currently the association between HLAs and certain diseases is of minimal practical clinical importance. Nevertheless, there is promise for the development of clinical applications in the future. For example, with certain autoimmune diseases, it may be possible to identify members of a family at greatest risk for developing the same or a related autoimmune disease. These people would need close medical supervision, implementation of preventive measures (if possible), and early diagnosis and treatment to prevent chronic complications.

ORGAN TRANSPLANTATION

Transplantation success has improved with advances in surgical technique, advances in histocompatibility testing, and more effective immunosuppressants. Common tissue transplants include corneas, skin, bone marrow, heart valves, bone, and connective tissues (Fig. 14-11). Cornea transplants can prevent or correct blindness. Skin grafts are used in managing burn patients. Bone marrow is donated to help patients with leukemias and other malignancies.

Transplanted organs currently come from many different body systems. These organs include the heart, lung, liver, kid-

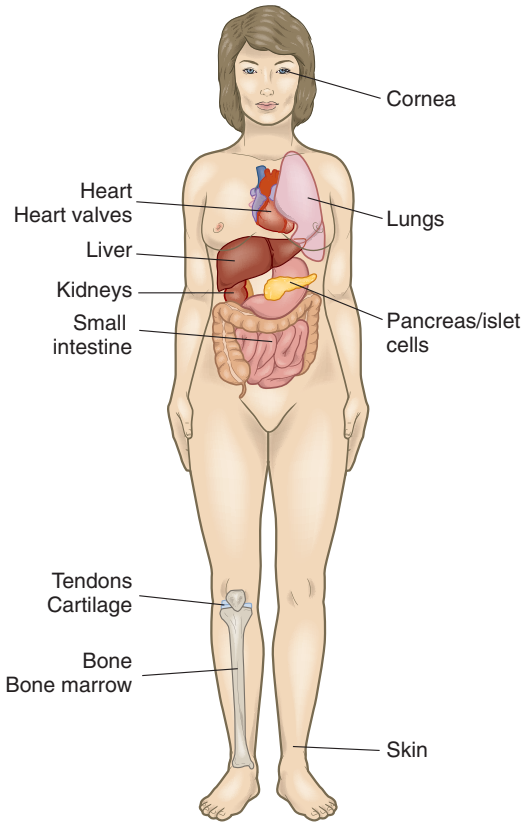

FIG. 14-11 Tissues and organs that can be transplanted.

ney, pancreas, and intestine. Certain organs can be transplanted together, such as kidney and pancreas, kidney and liver, and kidney and heart. For example, many diabetic patients who receive a pancreas transplant also receive a kidney transplant because the diabetes has not only impaired the pancreas, but also led to renal failure.

Some organs can be transplanted in parts or segments instead of transplanting an entire organ. Liver and lung lobes (rather than the whole organ) may be transplanted, or an intestine may be used in segments, thus allowing for one person's organ donation to benefit many recipients. This technique also enables living donors to donate part of an organ (or one of their organs in the case of kidneys).

Organ donations are taken from two sources: deceased (cadaver) and living donors. Most organs and tissues currently come from deceased donors. However, because of the shortage of organs from deceased donors, the use of both related and living unrelated donor organs is increasing.[11]

Individuals can make a decision to become a donor when they sign a donor card, the back of their driver's license, or a donor registry (depending on the state) and indicate their wish to donate organs. However, on their death or imminent death, ultimately the person's legal next of kin must consent to the donation regardless of whether the donor card is signed. That is why it is extremely important for people to notify their next of kin about their willingness to donate organs or tissues at the time of death.

Currently more than 115,000 people are on the organ procurement and transplantation network's national waiting list, which is maintained by the United Network for Organ Sharing (UNOS). However, fewer than 30,000 people receive transplants annually. The organs in highest demand are kidneys, hearts, and livers. These are also the most commonly transplanted organs.[12]

Organ and tissue donations are regulated by the Uniform Anatomical Gift Act to allow for fair and consistent transplantation laws among all states.[13] Patients are matched to available donors based on a number of factors: ABO blood and HLA typing, medical urgency, time on the waiting list, and geographic location.

Tissue Typing

The recipient usually receives a transplant from an ABO blood group–compatible donor (see Table 30-8). The donor and recipient do not need to share the same Rh factor.

HLA Typing. HLA typing is done on potential donors and recipients. Currently only the A, B, and DR antigens are thought to be clinically significant for transplantation. Because each locus has two alleles that encode for antigens, a total of six antigens are identified. In transplantation an attempt is made to match as many antigens as possible between the HLA-A, HLA-B, and HLA-DR loci. Antigen matches of five and six antigens and certain four-antigen matches have been found to have better clinical outcomes (i.e., the patient is less likely to reject the transplanted organ), especially in kidney and bone marrow transplants.

The degree of HLA matching required or deemed suitable for successful solid organ transplantation depends on the type of organ. Certain organ and tissue transplants require a closer histocompatibility match than other organs. For example, a cornea transplant can be accepted by nearly any individual because corneas are avascular and therefore no antibodies reach the cornea to cause rejection. In kidney and bone marrow transplantation, HLA matching is very important, since these transplants are at high risk for graft rejection. On the other hand, for liver transplants, HLA mismatches have little impact on graft survival. For heart and lung transplants, they fall somewhere in between, but minimizing HLA mismatches significantly improves survival. In addition, for liver, lung, and heart transplants, few donors are available and it is difficult to get good HLA matches.

Transporting and storing donated organs can take time. The "best" match may live many miles from the "ideal" recipient. The need to have the "best" matches has to be balanced against the time it takes to harvest and transport a donated organ and then transplant it.

Panel of Reactive Antibodies. A *panel of reactive antibodies (PRA)* indicates the recipient's sensitivity to various HLAs before receiving a transplant. To detect preformed antibodies to HLA, the recipient's serum is mixed with a randomly selected panel of donor lymphocytes to determine reactivity. The potential recipient may have been exposed to HLA antigens by means of previous blood transfusions, pregnancy, or a previous organ transplant.

For the PRA, the results are calculated in percentages. A high PRA indicates that the person has a large number of cytotoxic antibodies and is highly sensitized, which means there is a poor chance of finding a crossmatch-negative donor. In patients awaiting transplantation, a PRA panel is usually done on a regular basis. Plasmapheresis and IV immune globulin have been used to lower the number of preformed HLA antibodies in highly sensitized patients.

Crossmatch. A *crossmatch* uses serum from the recipient mixed with donor lymphocytes to test for any preformed anti-

HLA antibodies to the potential donor organ. The crossmatch can be used as a screening test when multiple possible living donors are being considered or once a cadaver donor is selected. A final crossmatch is done just before transplant.

A positive crossmatch indicates that the recipient has cytotoxic antibodies to the donor and is an absolute contraindication to transplantation. If transplanted, the organ would undergo hyperacute rejection. A negative crossmatch indicates that no preformed antibodies are present and it is safe to proceed with transplantation. Crossmatching, which is especially important for kidney transplants, may not be done for lung, liver, and heart transplants.

Transplant Rejection

Rejection is one of the major problems following organ transplantation. Rejection of organs occurs as a normal immune response to foreign tissue. The rejection can be prevented by using immunosuppression therapy, performing ABO and HLA matching, and ensuring that the crossmatch is negative. Unfortunately, many different HLAs exist, and a perfect match is nearly impossible unless the tissue is from oneself, an identical twin, or in some cases a sibling. Rejection can be hyperacute, acute, or chronic. Prevention, early diagnosis, and treatment of rejection are essential for long-term graft function.

Hyperacute Rejection. *Hyperacute rejection* occurs minutes to hours after transplantation because the blood vessels are rapidly destroyed. It occurs because the person had preexisting antibodies against the transplanted tissue or organ. There is no treatment for hyperacute rejection, and the transplanted organ is removed.

Fortunately hyperacute rejection is a rare event because the final crossmatch just before transplant usually determines whether the recipient is sensitized to any of the donor HLAs. On occasion, for unclear reasons, the final crossmatch does not detect these preformed antibodies, and hyperacute rejection occurs.

Acute Rejection. *Acute rejection* most commonly manifests in the first 6 months after transplantation. This type of rejection is usually mediated by the recipient's lymphocytes, which have been activated against the donated (foreign) tissue or organ (Fig. 14-12). In addition to cell-mediated rejection, another type of acute rejection occurs when the recipient develops antibodies to the transplanted organ.

It is not uncommon to have at least one rejection episode, especially with organs from deceased donors. These episodes are usually reversible with additional immunosuppressive therapy, which may include increased corticosteroid doses or polyclonal or monoclonal antibodies. Unfortunately, immunosuppressants increase the risk for infection. To combat acute rejection, all patients with transplants require long-term use of immunosuppressants, putting them at a high risk for infection, especially in the first few months after transplant when the immunosuppressive doses are highest.

Chronic Rejection. *Chronic rejection* is a process that occurs over months or years and is irreversible. Chronic rejection can occur for unknown reasons or from repeated episodes of acute rejection. The transplanted organ is infiltrated with large numbers of T and B cells characteristic of an ongoing, low-grade, immune-mediated injury. Chronic rejection results in fibrosis and scarring. In heart transplants it manifests as accelerated coronary artery disease. In lung transplants it manifests as bronchiolitis obliterans. In liver transplants it is characterized by loss of bile ducts. In kidney transplants it manifests as fibrosis and glomerulopathy.

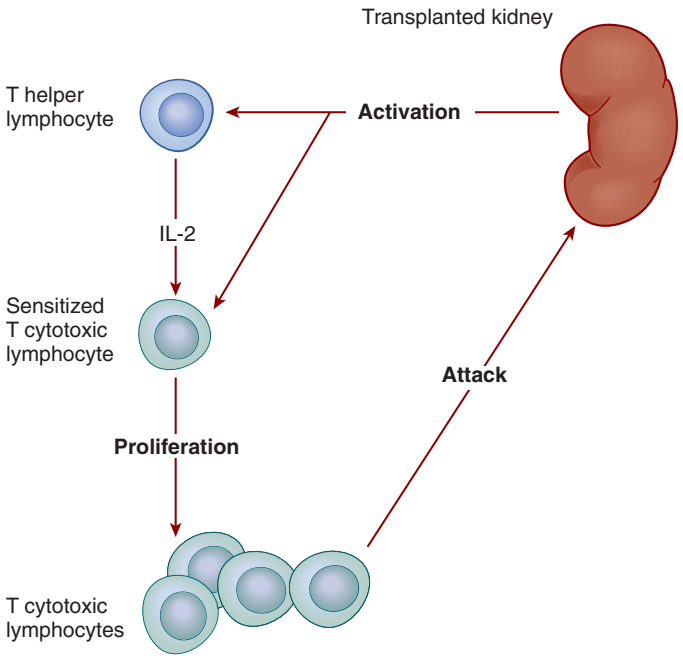

FIG. 14-12 Mechanism of action of T cytotoxic lymphocyte activation and attack of transplanted tissue. The transplanted organ (e.g., kidney) is recognized as foreign and activates the immune system. T helper cells are activated to produce interleukin-2 *(IL-2),* and T cytotoxic lymphocytes are sensitized. After the T cytotoxic cells proliferate, they attack the transplanted organ.

There is no definitive therapy for this type of rejection. Treatment is primarily supportive. This type of rejection is difficult to manage and is not associated with the optimistic prognosis of acute rejection.

Immunosuppressive Therapy

Immunosuppressive therapy requires a balance. On one hand, the immune response needs to be suppressed to prevent rejection of the transplanted organ. On the other hand, an adequate immune response needs to be maintained to prevent overwhelming infection and the development of malignancies.[14]

Many of the drugs used to achieve immunosuppression have significant side effects. Because transplant recipients must take immunosuppressants for life, the risk of toxicity continues for the rest of their lives.[15]

Immunosuppressant drugs are listed in Table 14-16. With use of a combination of agents that work during different phases of the immune response (Fig. 14-13), lower doses of each drug can be given to produce effective immunosuppression while minimizing side effects.

The major immunosuppressive agents are (1) calcineurin inhibitors, including cyclosporine (Sandimmune, Neoral, Gengraf) and tacrolimus (Prograf, FK506); (2) corticosteroids (prednisone, methylprednisolone [Solu-Medrol] IV); (3) mycophenolate mofetil (CellCept); and (4) sirolimus (Rapamune). Azathioprine (Imuran) and cyclophosphamide (Cytoxan) can also be used. Antilymphocyte globulin (ALG) and muromonab-CD3 (Orthoclone OKT3) are IV medications used for short periods to prevent early rejection or reverse acute rejection.

Immunosuppression protocols are highly variable among transplant centers, with different combinations of medications

TABLE 14-16 DRUG THERAPY

Immunosuppressive Therapy

Agent	Route	Mechanism of Action	Side Effects
Corticosteroids			
prednisone, methylprednisolone (Solu-Medrol)	PO, IV	Suppress inflammatory response. Inhibit cytokine production (IL-1, IL-6, TNF) and T cell activation and proliferation.	Peptic ulcers, hypertension, osteoporosis, Na^+ and H_2O retention, muscle weakness, easy bruising, delayed healing, hyperglycemia, ↑ risk for infection.
Calcineurin Inhibitors			
cyclosporine (Sandimmune,* Neoral,* Gengraf*) (Neoral and Gengraf are microemulsions with better absorption than Sandimmune.)	PO, IV	Acts on T helper cells to prevent production and release of IL-2 and γ-interferon. Inhibits production of T cytotoxic lymphocytes and B cells.	Nephrotoxicity, ↑ risk for infection, neurotoxicity (tremors, seizures), hepatotoxicity, lymphoma, hypertension, tremors, hirsutism, leukopenia, gingival hyperplasia.
tacrolimus (Prograf, FK506)	PO, IV	Same as cyclosporine but more effective.	Same as cyclosporine.
Cytotoxic (Antiproliferative) Drugs			
mycophenolate mofetil (CellCept) mycophenolate acid (Myfortic)	PO, IV	Inhibits purine synthesis. Suppresses proliferation of T and B cells.	Diarrhea, nausea and vomiting, severe neutropenia, thrombocytopenia, ↑ risk for infection, ↑ incidence of malignancies.
cyclophosphamide (Cytoxan, Neosar)	PO, IV	Cross-links DNA, leading to cell injury and death. Results in decrease in number and activity of T and B cells.	Neutropenia, hemorrhagic cystitis.
azathioprine (Imuran)	PO, IV	Blocks purine synthesis. Suppresses cell-mediated and humoral immune responses by inhibiting proliferation of T and B cells.	Bone marrow suppression: neutropenia, anemia, thrombocytopenia.
sirolimus (Rapamune)	PO	Binds to mammalian target of rapamycin (mTOR), thereby suppressing T cell activation and proliferation.	↑ Risk for infection, leukopenia, anemia, thrombocytopenia, hyperlipidemia, hypercholesterolemia, arthralgias, diarrhea. ↑ incidence of malignancies. Not used in liver and lung transplants.
everolimus (Zortress)	PO	Same as above	Peripheral edema, constipation, hypertension, nausea, anemia, urinary tract infection, hyperlipidemia.
Monoclonal Antibodies			
muromonab-CD3 (Orthoclone OKT3)	IV push	Monoclonal antibody that binds to CD3 receptors on T cells, causing cell lysis. Inhibits function of cytotoxic T cells.	Fever, chills, dyspnea, chest pain, nausea and vomiting. Anaphylactic reactions include pulmonary edema, cardiac or respiratory arrest.
daclizumab (Zenapax)	IV	Monoclonal antibody that acts as IL-2 receptor antagonist by inhibiting the binding of IL-2. Inhibits T cell activation and proliferation.	Can cause acute hypersensitivity reaction, including anaphylaxis.
basiliximab (Simulect)	IV	Same as daclizumab.	Same as daclizumab.
Polyclonal Antibody			
Lymphocyte immune globulin (Atgam)	IV	Prepared by immunizing horse with human T cells. Polyclonal antibodies directed against T cells, thus depleting them.	Serum sickness (fever, chills, muscle and joint pain), tachycardia, back pain, shortness of breath, hypotension, anaphylaxis, leukopenia, thrombocytopenia, rash, ↑ risk for infection.
Other			
belatacept (Nulojix)	IV	Prevents the activation of T cells.	Anemia, constipation, urinary tract infection, peripheral edema.

*Not bioequivalent and cannot be interchanged.
IL, Interleukin; *TNF,* tumor necrosis factor.

being used. Most patients are initially on triple therapy. The standard triple therapy usually includes a calcineurin inhibitor, a corticosteroid, and mycophenolate mofetil.

The doses of immunosuppressant drugs are reduced over time after the transplant. Patients taking corticosteroids may be weaned off after a few years. The trend in many transplant centers is to use immunosuppression protocols that do not contain corticosteroids because of their many side effects.

Calcineurin Inhibitors. This group of drugs, including tacrolimus and cyclosporine, is the foundation of most immunosuppression regimens. As the most effective immunosuppressants, these drugs prevent a cell-mediated attack against the transplanted organ (see Fig. 14-13). These drugs do not cause bone marrow suppression or alterations of the normal inflammatory response. They are generally used in combination with corticosteroids, mycophenolate mofetil, and sirolimus. Tacrolimus is the most widely used calcineurin inhibitor.[15]

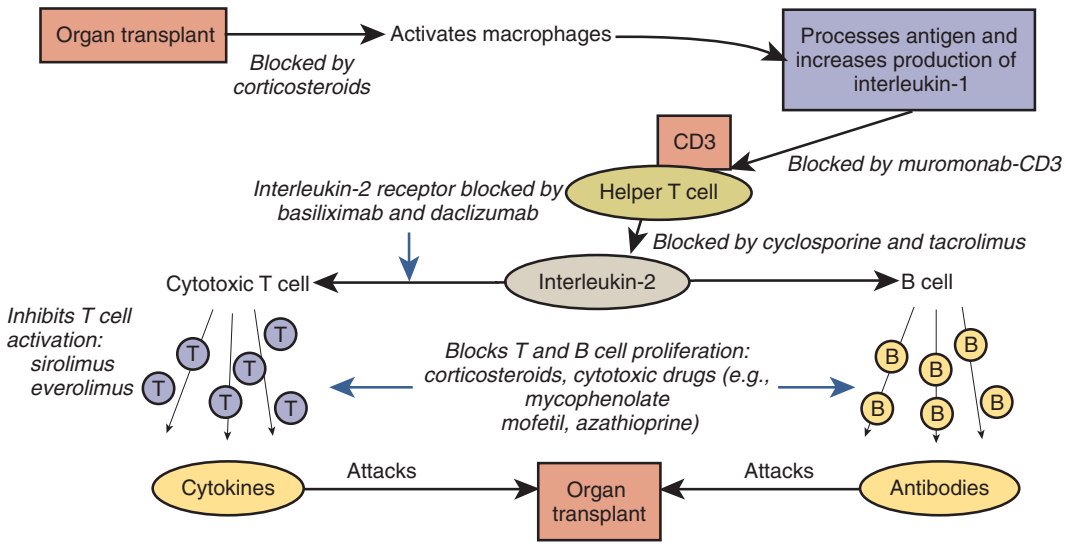

FIG. 14-13 Sites of action for immunosuppressive agents.

Many of the side effects of calcineurin inhibitors are dose related. These drugs are potentially nephrotoxic. Drug levels are monitored closely to prevent toxicity.

DRUG ALERT: Tacrolimus and Cyclosporine

- A substance in grapefruit and grapefruit juice prevents metabolism of these drugs.
- Consuming grapefruit or grapefruit juice while using these drugs could increase their toxicity.

Sirolimus. Sirolimus is an immunosuppressive agent approved for use in renal transplant recipients. It is used in combination with corticosteroids and cyclosporine. It is also used in combination with tacrolimus.

Mycophenolate Mofetil. Mycophenolate mofetil is a lymphocyte-specific inhibitor of purine synthesis with suppressive effects on both T and B lymphocytes. This drug appears to be most effective when used in combination with tacrolimus or cyclosporine. Its effects are additive because it acts later in the lymphocyte activation pathway by a different mechanism. It has also been shown to decrease the incidence of late graft loss. The major limitation of this drug is its GI toxicities, including nausea, vomiting, and diarrhea. In many cases the side effects can be diminished by lowering the dose or giving smaller doses more frequently.

DRUG ALERT: Mycophenolate Mofetil

- When given IV, it must be reconstituted in D_5W and no other solution.
- Do not give as IV bolus. Give over 2 or more hours.

Monoclonal Antibodies. Monoclonal antibodies are used for preventing and treating acute rejection episodes. (eFig. 14-2, showing how monoclonal antibodies are made, is available on the website for this chapter.) Muromonab-CD3 was the first of these monoclonal antibodies to be used in clinical transplantation. It is a mouse monoclonal antibody that binds with the CD3 antigen found on the surface of human thymocytes and mature T cells. It is an anti-antigen receptor antibody that interferes with the function of the T lymphocyte, the pivotal cell in the response to graft rejection. It is administered via IV bolus. All T cells are affected, rather than just the subset active in graft rejection. Within minutes after the initial infusion of muromonab-CD3, the number of circulating T cells decreases significantly.

A flulike syndrome occurs during the first few days of treatment because of cytokine release. Side effects include fever, rigors, headache, myalgias, and various GI disturbances. To reduce the expected side effects of muromonab-CD3, give patients acetaminophen (Tylenol), diphenhydramine (Benadryl), and IV methylprednisolone before administering the dose.

Newer generation monoclonal antibodies include daclizumab (Zenapax) and basiliximab (Simulect). These monoclonal antibodies are a hybrid of mouse and human antibodies and have fewer side effects than muromonab-CD3 because they have been "humanized."

Polyclonal Antibody. Lymphocyte immune globulin (Atgam) is used as induction therapy or to treat acute rejection. The purpose of induction therapy is to severely immunosuppress an individual immediately after transplantation to prevent early rejection. The drug is made by immunizing horses with human lymphocytes. The antibody made against the human lymphocytes is then purified and administered IV.

Allergic reactions to the foreign proteins from the host animal, manifested by fever, arthralgias, and tachycardia, are common but usually not severe enough to preclude use. These side effects can be attenuated by administering the preparation slowly, over 4 to 6 hours, and premedicating patients with acetaminophen, diphenhydramine, and methylprednisolone. The main toxicities of polyclonal antibodies are lymphopenia and thrombocytopenia caused by antibody contaminants that are not completely removed during preparation of the antibodies.

GRAFT-VERSUS-HOST DISEASE

Graft-versus-host disease (GVHD) occurs when an immunoincompetent (immunodeficient) patient receives immunocompetent cells.[16] A GVHD response may result from the infusion of any blood product containing viable lymphocytes, as in therapeutic blood transfusions, and from the transplantation of fetal thymus, fetal liver, or bone marrow. In most transplantation situations the biggest concern is the patient's (host's) rejection of the organ or transplant. However, in GVHD disease, the graft (donated tissue) rejects the host (recipient) tissue.

The GVHD response may begin 7 to 30 days after transplantation. Once the reaction is started, little can be done to modify

its course. The exact mechanism involved in this reaction is not completely understood. However, it involves donor T cells attacking and destroying vulnerable host cells.

The target organs for the GVHD phenomenon are the skin, liver, and GI tract. The skin disease may be a maculopapular rash, which may be pruritic or painful. It initially involves the palms and soles of the feet but can progress to a generalized erythema with bullous formation and desquamation (shedding of the outer layer of skin). The liver disease may range from mild jaundice with elevated liver enzymes to hepatic coma. The intestinal disease may be manifested by mild to severe diarrhea, severe abdominal pain, GI bleeding, and malabsorption.

The biggest problem with GVHD is infection, with different types of infections seen in different periods. Bacterial and fungal infections predominate immediately after transplantation when granulocytopenia exists. The development of interstitial pneumonitis is the primary concern later in the course of the disease.

There is no adequate treatment of GVHD once it is established. Although corticosteroids are often used, they enhance the susceptibility to infection. The use of immunosuppressive agents (e.g., methotrexate, cyclosporine) has been most effective as a preventive rather than a treatment measure. Radiation of blood products before they are administered is another measure to prevent T cell replication.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The function of monocytes in immunity is related to their ability to
   - **a.** stimulate the production of T and B lymphocytes.
   - **b.** produce antibodies on exposure to foreign substances.
   - **c.** bind antigens and stimulate natural killer cell activation.
   - **d.** capture antigens by phagocytosis and present them to lymphocytes.
2. One function of cell-mediated immunity is
   - **a.** formation of antibodies.
   - **b.** activation of the complement system.
   - **c.** surveillance for malignant cell changes.
   - **d.** opsonization of antigens to allow phagocytosis by neutrophils.
3. The reason newborns are protected for the first 6 months of life from bacterial infections is because of the maternal transmission of
   - **a.** IgG.
   - **b.** IgA.
   - **c.** IgM.
   - **d.** IgE.
4. In a type I hypersensitivity reaction the primary immunologic disorder appears to be
   - **a.** binding of IgG to an antigen on a cell surface.
   - **b.** deposit of antigen-antibody complexes in small vessels.
   - **c.** release of cytokines used to interact with specific antigens.
   - **d.** release of chemical mediators from IgE-bound mast cells and basophils.
5. The nurse is alerted to possible anaphylactic shock immediately after a patient has received intramuscular penicillin by the development of
   - **a.** edema and itching at the injection site.
   - **b.** sneezing and itching of the nose and eyes.
   - **c.** a wheal-and-flare reaction at the injection site.
   - **d.** chest tightness and production of thick sputum.
6. The nurse advises a friend who asks him to administer his allergy shots that
   - **a.** it is illegal for nurses to administer injections outside of a medical setting.
   - **b.** he is qualified to do it if the friend has epinephrine in an injectable syringe provided with his extract.
   - **c.** avoiding the allergens is a more effective way of controlling allergies, and allergy shots are not usually effective.
   - **d.** immunotherapy should only be administered in a setting where emergency equipment and drugs are available.
7. Association between HLA antigens and diseases is most commonly found in what disease conditions?
   - **a.** Malignancies
   - **b.** Infectious diseases
   - **c.** Neurologic diseases
   - **d.** Autoimmune disorders
8. A patient is undergoing plasmapheresis for treatment of systemic lupus erythematosus. The nurse explains that plasmapheresis is used in her treatment to
   - **a.** remove T lymphocytes in her blood that are producing antinuclear antibodies.
   - **b.** remove normal particles in her blood that are being damaged by autoantibodies.
   - **c.** exchange her plasma that contains antinuclear antibodies with a substitute fluid.
   - **d.** replace viral-damaged cellular components of her blood with replacement whole blood.
9. The most common cause of secondary immunodeficiencies is
   - **a.** drugs.
   - **b.** stress.
   - **c.** malnutrition.
   - **d.** human immunodeficiency virus.
10. What accurately describes rejection following transplantation?
    - **a.** Hyperacute rejection can be treated with OKT3.
    - **b.** Acute rejection can be treated with sirolimus or tacrolimus.
    - **c.** Chronic rejection can be treated with tacrolimus or cyclosporine.
    - **d.** Hyperacute reaction can usually be avoided if crossmatching is done before the transplantation.
11. In a person having an acute rejection of a transplanted kidney, what would help the nurse understand the course of events *(select all that apply)*?
    - **a.** A new transplant should be considered.
    - **b.** Acute rejection can be treated with OKT3.
    - **c.** Acute rejection usually leads to chronic rejection.
    - **d.** Corticosteroids are the most successful drugs used to treat acute rejection.
    - **e.** Acute rejection is common after a transplant and can be treated with drug therapy.

1. d, 2. c, 3. a, 4. d, 5. a, 6. d, 7. d, 8. c, 9. a, 10. d, 11. b, e

LEARNING OUTCOMES

1. Evaluate the impact of emerging and reemerging infections on health care.
2. Identify ways to decrease the development of resistance to antibiotics.
3. Explain the ways human immunodeficiency virus (HIV) is transmitted and the factors that affect transmission.
4. Describe the pathophysiology of HIV infection.
5. Chart the spectrum of untreated HIV infection.
6. Identify the diagnostic criteria for acquired immunodeficiency syndrome (AIDS).
7. Describe methods used to test for HIV infection.
8. Discuss the collaborative management of HIV infection.
9. Summarize the characteristics of opportunistic diseases associated with AIDS.
10. Describe the potential complications associated with long-term treatment of HIV infection.
11. Compare and contrast HIV prevention methods.
12. Describe the nursing management of HIV-infected patients and HIV-at-risk patients.

This chapter presents a brief overview of infections (both emerging and health care–associated infections). In addition, this chapter provides a comprehensive discussion of human immunodeficiency (HIV) infection focusing on transmission, pathophysiology, collaborative care, and nursing management.

INFECTIONS

Infections, such as lower respiratory tract infections, malaria, HIV, and tuberculosis (TB), are responsible for a significant number of deaths worldwide.[1] Infection occurs when a *pathogen* (a microorganism that causes disease) invades the body, begins to multiply, and produces disease, usually causing harm to the host. The signs and symptoms of infection are a result of specific pathogen activity, which triggers inflammation and other immune responses.[2]

Infections can be divided into localized, disseminated, and systemic disease. A *localized* infection is limited to a small area. A *disseminated* infection has spread to areas of the body beyond the initial site of infection. *Systemic* infections have spread extensively throughout the body, often via the blood.

Reviewed by Danette Y. Wall, ACRN, MSN, MBA/HCM, ISO9001 Lead Auditor, Regional Nurse, Department of Veterans Affairs–Veterans Health Administration, Tampa, Florida.

TYPES OF PATHOGENS

The many different kinds of pathogens can be classified into several groups, including bacteria, viruses, fungi, protozoa, and prions.[3] *Bacteria* are one-celled organisms that are common throughout nature. Many bacteria are normal flora. They live harmoniously in or on the human body without causing disease under normal circumstances. Normal flora protect the human body by preventing the overgrowth of other microorganisms. For example, *Escherichia coli* is a bacteria that is part of the normal flora in the large intestine.

Bacteria cause disease in two ways: by entering the body and growing inside human cells (e.g., TB) or by secreting toxins that damage cells (e.g., *Staphylococcus aureus*). Bacteria are divided into categories based on the shape of their cells. *Cocci*, such as streptococci and staphylococci, are round. *Bacilli* are rod shaped and include tetanus and TB. *Curved rods* include *Vibrio* bacteria, one of which causes cholera. *Spirochetes* are spiral shaped and include the organisms that cause leprosy and syphilis. Table 15-1 lists common pathogenic bacteria and the diseases that they cause.

Viruses, unlike bacteria, do not have a cellular structure. They are simple infectious particles that consist of a small amount of genetic material (either ribonucleic acid [RNA] or deoxyribonucleic acid [DNA]) and a protein envelope. Viruses can reproduce only after releasing their genetic material into the cell of another living organism. Examples of diseases caused by viruses are shown in Table 15-2.

Fungi are organisms similar to plants, but they lack chlorophyll. *Mycosis* is any disease caused by a fungus. Pathogenic fungi cause infections that are usually localized but can become disseminated in an immunocompromised person. Tinea pedis

TABLE 15-1 DISEASE-CAUSING BACTERIA

Bacteria	Diseases Caused
Clostridia	
• *Clostridium botulinum*	Food poisoning with progressive muscle paralysis
• *Clostridium tetani*	Tetanus (lockjaw)
Corynebacterium diphtheriae	Diphtheria
Escherichia coli	Urinary tract infections, peritonitis, hemolytic-uremic syndrome
Haemophilus	
• *Haemophilus influenzae*	Nasopharyngitis, meningitis, pneumonia
• *Haemophilus pertussis*	Pertussis (whooping cough)
Helicobacter pylori	Peptic ulcers, gastritis
Klebsiella-Enterobacter organisms	Urinary tract infections, peritonitis, pneumonia
Legionella pneumophila	Pneumonia (Legionnaires' disease)
Mycobacteria	
• *Mycobacterium leprae*	Hansen's disease (leprosy)
• *Mycobacterium tuberculosis*	Tuberculosis
Neisseriae	
• *Neisseria gonorrhoeae*	Gonorrhea, pelvic inflammatory disease
• *Neisseria meningitidis*	Meningococcemia, meningitis
Proteus species	Urinary tract infections, peritonitis
Pseudomonas aeruginosa	Urinary tract infections, meningitis
Salmonella	
• *Salmonella typhi*	Typhoid fever
• Other *Salmonella* organisms	Food poisoning, gastroenteritis
Shigella	Shigellosis; diarrhea, abdominal pain, and fever (dysentery)
Staphylococcus aureus	Skin infections, pneumonia, urinary tract infections, acute osteomyelitis, toxic shock syndrome
Streptococci	
• *Streptococcus faecalis*	Genitourinary infection, infection of surgical wounds
• *Streptococcus pneumoniae*	Pneumococcal pneumonia
• *Streptococcus pyogenes* (group A β-hemolytic streptococci)	Pharyngitis, scarlet fever, rheumatic fever, acute glomerulonephritis, erysipelas, pneumonia
• *S. pyogenes* (group B β-hemolytic streptococci)	Urinary tract infections
• *Streptococcus viridans*	Bacterial endocarditis
Treponema pallidum	Syphilis

TABLE 15-2 DISEASE-CAUSING VIRUSES

Virus	Diseases Caused
Adenoviruses	Upper respiratory tract infection, pneumonia
Arbovirus	Syndrome of fever, malaise, headache, myalgia; aseptic meningitis; encephalitis
Coronavirus	Upper respiratory tract infection
Coxsackieviruses A and B	Upper respiratory tract infection, gastroenteritis, acute myocarditis, aseptic meningitis
Echoviruses	Upper respiratory tract infection, gastroenteritis, aseptic meningitis
Hepatitis A, B, C	Viral hepatitis
Herpesviruses	
• Cytomegalovirus (CMV)	Gastroenteritis; pneumonia and retinal damage in immunosuppressed individuals, infectious mononucleosis–like syndrome
• Epstein-Barr	Mononucleosis, Burkitt's lymphoma (possibly)
• Herpes simplex type 1	Herpes labialis ("fever blisters"), genital herpes infection
• Herpes simplex type 2	Genital herpes infection
• Varicella-zoster	Chickenpox, shingles
Human immunodeficiency virus (HIV)	HIV infection, AIDS
Influenza A and B	Upper respiratory tract infection, H1N1 (swine) flu, avian (bird) flu
Mumps	Parotitis, orchitis in postpubertal males
Papillomavirus	Warts
Parainfluenza 1-4	Upper respiratory tract infection
Parvovirus	Gastroenteritis
Poliovirus	Poliomyelitis
Pox viruses	Smallpox
Reoviruses 1, 2, 3	Upper respiratory tract infection
Respiratory syncytial virus	Gastroenteritis, respiratory tract infection
Rhabdovirus	Rabies
Rhinovirus	Upper respiratory tract infection, pneumonia
Rotaviruses	Gastroenteritis
Rubella	German measles
Rubeola	Measles
West Nile virus	Flulike symptoms, meningitis, encephalitis

TABLE 15-3 DISEASE-CAUSING FUNGI

Fungi	Diseases Caused	Organs Affected
Aspergillus fumigatus	Aspergillosis Otomycosis	Lungs* Ears
Blastomyces dermatitidis	Blastomycosis	Lungs, various organs
Candida albicans	Candidiasis Vaginitis Thrush	Intestines Vagina Skin,† mouth
Coccidioides immitis	Coccidioidomycosis	Lungs*
Pneumocystis jiroveci	Pneumocystis pneumonia (PCP)	Lungs*
Sporothrix schenckii	Sporotrichosis	Skin, lymph vessels
Trichophyton	Tinea pedis	Skin†
Microsporum	Tinea capitis	Skin†
Epidermophyton	Tinea corporis	Skin†

*See Table 28-14: Fungal Infections of the Lung.
†See Table 24-6: Common Fungal Infections of the Skin.

(athlete's foot) and tinea corporis (ringworm) are two common mycotic infections. Some fungi are normal flora in the body, but when overgrowth occurs, disease can result. Overgrowth of *Candida albicans,* for example, can cause candidiasis in the mouth (thrush), esophagus, intestines, and vagina. Other fungi and their respective mycotic infections are listed in Table 15-3.

Protozoa are single-cell, animal-like microorganisms. Protozoa normally live in soil and bodies of water. When introduced into the human body, they can cause infection. Amebic dysentery and giardiasis are caused by protozoal parasites. Malaria is caused by a sporozoa called *Plasmodium malariae.*

Prions are infectious particles that contain abnormally shaped proteins. Not all prions cause disease, but those that do typically affect the nervous system. They can cause a group of illnesses called transmissible spongiform encephalopathies (TSEs). Some of the more common TSEs are Creutzfeldt-Jakob disease and bovine spongiform encephalopathy in cattle (also known as mad cow disease).[4]

EMERGING INFECTIONS

An **emerging infection** is an infectious disease that has recently increased in incidence or that threatens to increase in the immediate future. Examples of emerging infections are described in Table 15-4. Emerging infectious diseases can originate from unknown sources or from contact with animals, changes in known diseases, or biologic warfare. For example, severe acute respiratory syndrome (SARS) and the West Nile virus come from animal sources. Others emerged when a previously treatable organism (e.g., *S. aureus*) developed resistance to antibiotics.

The battle against infection is not new, but modern technologies have changed the rules of the game. Global travel, population density, encroachment into new environments, misuse of antibiotics, and bioterrorism have increased the risk for widespread distribution of emerging infections.[5]

Not too long ago many believed that science had conquered infectious disease. However, newly recognized infectious diseases have emerged in recent decades. These include HIV, Lyme disease, hepatitis C, SARS, Ebola virus, and influenza A (H1N1) virus. Some diseases once thought to be under control, such as TB, measles, and pertussis, have reemerged.[6]

TABLE 15-4 EMERGING INFECTIONS

Microorganism	Related Disease
Bacteria	
Borrelia burgdorferi	Lyme disease
Campylobacter jejuni	Diarrhea
Escherichia coli O157:H7	Hemorrhagic colitis, hemolytic-uremic syndrome
Helicobacter pylori	Peptic ulcer disease
Legionella pneumophila	Pneumonia (Legionnaires' disease)
Vibrio cholerae 0139	New strain associated with epidemic cholera
Virus	
Ebola virus	Ebola hemorrhagic fever
H1N1	H1N1 (swine) flu
Hantavirus	Hemorrhagic fever associated with severe pulmonary syndrome
Hepatitis C virus	Parenterally transmitted hepatitis
Hepatitis E virus	Enterically transmitted hepatitis
Human immunodeficiency virus (HIV)	HIV infection and AIDS
Human herpesvirus 6 (HHV-6)	Roseola subitum
Human herpesvirus 8 (HHV-8)	Associated with Kaposi sarcoma in immunosuppressed patients, including people with HIV infection
West Nile virus	West Nile fever
Parasite	
Cryptosporidium parvum	Acute and chronic diarrhea

Studies in *zoonosis* (the science of transmission of diseases from animals to humans) have shown that many known infectious diseases come from animal and insect vectors. The SARS outbreak in China in 2003, for instance, was linked to the civet cat, a small carnivorous mammal found throughout much of Asia and Africa. (SARS is discussed in Chapter 68.)

West Nile virus is carried and transmitted by mosquitoes. Mosquitoes acquire the virus as they draw blood from infected animals and people. The virus does not cause illness in the mosquito, but can be transferred to uninfected animals and humans as the mosquito continues to feed. Bird deaths are an early warning sign of a West Nile virus outbreak, which can spread quickly if action is not taken in a timely manner. (West Nile virus is discussed in Chapter 57.)

Influenza viruses are examples of how disease can spread between animals and humans. Variants of influenza A viruses were responsible for influenza epidemics. These include the 2009 influenza A (H1N1) outbreak that was traced back to pigs, hence the name *swine flu.* In 1997 and 2003 outbreaks of the influenza A (H5N1) strain of avian flu resulted from transmission of influenza virus from chickens to humans.[7]

Ebola virus has presented an ongoing challenge to public health since it was first seen in 1976. Ebola virus causes severe hemorrhagic fever and is usually lethal. Therapeutic and preventive measures are extremely limited. The natural reservoir and path of transmission are unknown, which makes it impossible to effectively combat Ebola virus and the disease it causes.[8]

Reemerging Infections

Vaccines and proper medications have led to the near eradication of some infections (e.g., smallpox and polio), but infective

TABLE 15-5 REEMERGING INFECTIONS

Microorganism	Infection	Description
Bacteria		
Corynebacterium diphtheriae	Diphtheria	Localized infection of mucous membranes or skin.
Bordetella pertussis	Pertussis	Acute, highly contagious respiratory disease characterized by loud whooping inspiration. Also known as whooping cough.
Yersinia pestis	Plague	*Bubonic:* swollen glands, fever, chills, headache, and extreme exhaustion. *Pneumonic:* overwhelming pneumonia with high fever, cough, bloody sputum, and chills.
Mycobacterium tuberculosis	Tuberculosis	Chronic infection transmitted by inhalation of infected droplets (see Chapter 28).
Virus		
Dengue viruses (flaviviruses)	Dengue fever	Acute infection transmitted by mosquitoes and occurring mainly in tropical and subtropical regions.
Parasite		
Giardia	Giardiasis	Diarrheal illness that usually originates in water contaminated with fecal matter. Also known as traveler's diarrhea.

TABLE 15-6 ANTIBIOTIC-RESISTANT ORGANISMS AND TREATMENT

Bacteria	Resistant To	Preferred Treatment
Staphylococcus aureus	methicillin*	vancomycin (Vancocin)
Staphylococcus epidermidis	methicillin*	vancomycin
Enterococcus faecalis	vancomycin streptomycin gentamicin (Garamycin)	penicillin G or ampicillin
Enterococcus faecium	vancomycin streptomycin gentamicin	penicillin G or ampicillin
Streptococcus pneumoniae	penicillin G	ceftriaxone (Rocephin) cefotaxime (Claforan)
Klebsiella pneumoniae	Third-generation cephalosporins (e.g., ceftazidime [Ceptaz, Fortaz])	imipenem and cilastatin (Primaxin) meropenem (Merrem IV)

*This drug is no longer available in the United States.

agents can reemerge if conditions are right. Table 15-5 presents some diseases that have shown resurgence in recent decades.

For example, the incidence of TB began to steadily decrease in the mid-1950s, but in 1984 TB cases began to rise. The growing HIV epidemic in the 1970s and 1980s contributed to the increase in TB as people with depressed immune systems developed new cases of TB or reactivated dormant TB infections. The emergence of multidrug-resistant forms of TB (MDR-TB) also contributed to the increase. Local and federal governments took measures to address the problem, and the rates of TB are now slowly declining again.[9] (TB is discussed in Chapter 28.)

International travel has created a new obstacle for the local eradication of diseases. For example, measles is no longer considered endemic in the United States, but it remains a leading cause of morbidity in developing countries, and outbreaks have occurred in the United States, typically in areas with low vaccination rates. Some measles cases in the United States have been found in people who have recently traveled to measles-endemic areas.[10]

Antibiotic-Resistant Organisms

Resistance occurs when pathogenic organisms change in ways that decrease the ability of a drug (or a family of drugs) to treat disease.[3] Microorganisms can become resistant to classic treatments (e.g., penicillin), as well as to newer antibiotics and antiviral agents. Microorganisms are highly adaptable. They have evolved genetic and biochemical mechanisms to defend against antimicrobial actions. Genetic mechanisms include mutation and acquisition of new DNA or RNA. Biochemically, bacteria can resist antibiotics by producing enzymes that destroy or inactivate the drugs. Drug target sites are then altered so that the antibiotic cannot bind to or enter the bacteria. If the drug cannot enter the cell, it cannot kill the bacteria. Table 15-6 describes the most common antibiotic-resistant bacteria.

Methicillin-resistant *S. aureus* (MRSA), vancomycin-resistant enterococci (VRE), and penicillin-resistant *Streptococcus pneumoniae* are examples of emerging strains of antibiotic-resistant organisms. These drug-resistant bacteria were initially seen primarily in health care settings, but are becoming more prevalent in the community. For example, MRSA, a form of *S. aureus* that does not respond to methicillin- or penicillin-based therapies, was initially considered a health care–associated infection (HA-MRSA). However, over the past decade a variant strain of MRSA that is primarily acquired in the community (community-acquired MRSA [CA-MRSA]) has emerged.[11] This strain of MRSA is more *virulent* (able to cause disease or infection) compared with HA-MRSA. CA-MRSA has been known to cause rapidly forming skin infections and systemic diseases, including pneumonia and sepsis. Rates of CA-MRSA infections appear to be on the rise. Conversely, there has been a reduction in HA-MRSA with the implementation of strict hygiene measures in health care settings.

VRE is another antibiotic-resistant bacteria that has become a concern for patients and health care workers. VRE is more virulent than MRSA and can remain viable on environmental surfaces for weeks.[12] Although antibiotic-resistant bacteria can infect anyone, patients who are hospitalized and those with immunosuppression are more likely to be exposed to these bacteria and to develop infection.

Health care providers have contributed to the development of drug-resistant organisms by (1) administering antibiotics for viral infections, (2) succumbing to pressures from patients to prescribe unnecessary antibiotic therapy, (3) using inadequate drug regimens to treat infections, or (4) using broad-spectrum or combination agents for infections that should be treated with first-line medications. Patients can also contribute to resistance development by (1) skipping doses, (2) not taking antibiotics for the full duration of prescribed therapy, or (3) saving unused antibiotics "in case I need them later." In addition, limited

TABLE 15-7 PATIENT & CAREGIVER TEACHING GUIDE

Decrease Risk for Antibiotic-Resistant Infection

Include the following instructions when teaching patients or their caregivers how to decrease the risk for antibiotic-resistant infection.

1. Do Not Take Antibiotics to Prevent Illness (unless prescribed)

Doing this increases your risk for developing resistant infection. Exceptions include taking antibiotics as prescribed before certain surgeries and dental work or in the presence of immune dysfunction.

2. Wash Your Hands Frequently

Hand washing is the single most important thing you can do to prevent infection.

3. Follow Directions When Taking Antibiotics

Not taking your antibiotic as prescribed or skipping doses can allow antibiotic-resistant bacteria to develop.

4. Do Not Request an Antibiotic for Flu or Colds

If your health care provider says that you do not need an antibiotic, chances are you do not. Antibiotics are effective against bacterial infections but not viruses, which cause colds and flu.

5. Finish Your Antibiotic

Do not stop taking your antibiotic when you feel better. If you stop taking your antibiotic early, the hardiest bacteria survive and multiply. Eventually you could develop an infection resistant to many antibiotics. You should never have leftover antibiotics.

6. Do Not Take Leftover Antibiotics

Do not save unfinished antibiotics for later use or borrow leftover drugs from family or friends. This is dangerous because (1) the leftover antibiotic may not be appropriate for you, (2) your illness may not be a bacterial infection, (3) old antibiotics can lose their effectiveness and in some cases can even be fatal, and (4) there will not be enough doses in a leftover bottle to provide full treatment.

resources and access to medications make it difficult for some patients to get adequate treatment for infections. Teaching patients and their families the proper use of antibiotics (Table 15-7) is crucial to treatment success and prevention of drug-resistant pathogens. The Centers for Disease Control and Prevention (CDC), the Infectious Diseases Society of America, and many health care organizations have been campaigning for greater vigilance in minimizing the misuse of antibiotics in reaction to this growing concern.

HEALTH CARE–ASSOCIATED INFECTIONS

Health care–associated infections (HAIs), formerly referred to as *nosocomial infections,* are infections that are acquired as a result of exposure to a microorganism in a health care setting. Approximately 2 million HAIs and 99,000 HAI-associated deaths occur in the United States each year. Antibiotic-resistant organisms cause half of these infections.[13] Up to 10% of hospitalized patients will acquire an HAI. Surgical and immunocompromised patients are at highest risk. Any organism can cause HAIs, but certain bacteria, including *E. coli, S. aureus, Enterobacter aerogenes,* and various types of streptococci, are the more common culprits. Some bacteria that do not normally cause disease can cause infections in high-risk patients as a result of illness or treatment of illness.[14]

TABLE 15-8 OSHA REQUIREMENTS FOR PERSONAL PROTECTIVE EQUIPMENT

The following equipment is used to minimize exposure to blood-borne pathogens.

Equipment	Indications for Use
Gloves	• Must be used when the employee can reasonably anticipate having contact with blood or other potentially infectious materials, when performing vascular access procedures, and when handling or touching contaminated items or surfaces. • Gloves must be replaced if torn, punctured, or contaminated or their ability to function as a barrier is compromised.
Clothing (gowns, aprons, caps, boots)	• Must be used when occupational exposure is anticipated. • The type and characteristics depend on the task and degree of exposure anticipated.
Face protection (mask and glasses with solid side shields or a chin-length face shield)	• Must be used when splashes, sprays, spatters, or droplets of blood or other potentially infectious materials pose a hazard to the eyes, nose, or mouth.

Source: Occupational Safety and Health Administration: Bloodborne pathogens and needlestick prevention. Retrieved from *www.osha.gov/SLTC/bloodbornepathogens*.
NOTE: Employers must provide, make accessible, and require the use of personal protective equipment (PPE) at no cost to the employee. PPE also must be provided in appropriate sizes. Hypoallergenic gloves or similar alternatives must be made available to employees who have an allergic sensitivity to gloves.
OSHA, Occupational Safety and Health Administration.

Approximately one third of HAIs are preventable. Health care providers often transmit HAIs from patient to patient through direct contact. Hand washing (or using an alcohol-based hand sanitizer) between patients and procedures and the appropriate use of protective equipment such as gloves remain the first lines of defense to prevent the spread of HAIs. Isolated infections can also be caused when bacteria that normally stay in one area of the body are introduced into another area. Therefore care must be taken to change gloves and wash hands when moving from one task to another, even when working with the same patient.[15] The Occupational Safety and Health Administration (OSHA) and the CDC recommend that precautions be followed to control the spread of disease, especially of antibiotic-resistant organisms (Table 15-8).

GERONTOLOGIC CONSIDERATIONS

INFECTIONS IN OLDER ADULTS

For older adults the rate of HAIs is two or three times higher than for younger patients.[13,16] Individuals in long-term care facilities are at special risk for HAI. Age-related changes (e.g., impaired immune function, co-morbidities such as diabetes, physical disabilities) can contribute to higher infection rates.[17]

Infections common in older adults include pneumonia, urinary tract infections, skin infections, and TB. Urinary tract infections are more common in older adults who reside in long-term care facilities. Patients with indwelling catheters are at particular risk. Infections in older adults often have atypical manifestations, such as cognitive and behavioral changes, before the emergence of fever, pain, or alterations in laboratory values.

Suspicion of disease should typically begin if a patient demonstrates changes in the ability to perform daily activities or in cognitive function. In addition, underlying diseases, increased frequency of drug reactions, and institutionalization can all complicate the management of the older adult with infection.

SAFETY ALERT

- Do not rely on the presence of fever to indicate infection in older adults because many have lower core body temperatures and decreased immune responses.

INFECTION PREVENTION AND CONTROL

Occupational Safety and Health Administration (OSHA) Guidelines

OSHA is a federal agency that protects workers from injury and illness in places of employment and supports activities that minimize or eliminate exposure to infectious materials in the workplace. OSHA mandates that any employer whose employees could be exposed to potentially infectious materials implement standard policies and procedures for protection of those employees. Employees must be provided with appropriate personal protective equipment (PPE) and safety equipment. These include gloves, gowns, facial protection, and disposal systems for sharps (see Table 15-8). Appropriate PPE varies depending on the situation, and as a nurse, you need to use sound judgment when deciding when and how to use protective equipment.

Infection Precautions

If a patient is admitted with or develops an infection that is considered a risk to others, infection precautions may be needed. The CDC has established guidelines with two levels of precautions: (1) *standard precautions*, designed for the care of all patients in hospitals and health care facilities; and (2) *transmission-based precautions,* designed for specific diseases.[15] The purpose of these precautions is to prevent the transmission of organisms from patients to health care providers, from health care providers to patients, from patients to other patients, and from providers and patients to people outside of the hospital. (CDC guidelines for isolation precautions are summarized in eTable 15-1 on the website for this chapter.)

The *standard precautions* system applies to (1) blood; (2) all body fluids, secretions, and excretions; (3) nonintact skin; and (4) mucous membranes. Standard precautions are designed to reduce the risk of transmission of microorganisms in hospitals. Standard precautions should be applied to all patients regardless of diagnosis or presumed infection status. The CDC's standard precautions incorporate all of the OSHA blood-borne pathogens standard requirements.

Transmission-based precautions are used for patients known to be or suspected of being infected with highly transmissible or epidemiologically important pathogens that require additional precautions to interrupt transmission and prevent infection. Transmission-based precautions include airborne precautions, droplet precautions, and contact precautions. *Airborne precautions* are used if the organism can cause infection over long distances when suspended in the air (e.g., TB, rubeola). *Droplet precautions* are used to minimize contact with pathogens that are spread through the air at close contact and that affect the respiratory system or mucous membranes (e.g., influenza, pertussis). *Contact precautions* are used to minimize the spread of pathogens that are acquired from direct or indirect contact, especially multidrug-resistant organisms (e.g., MRSA, VRE). Transmission-based precautions may be combined for diseases that have multiple routes of transmission. Whether used alone or in combination, transmission-based precautions should always be used in conjunction with standard precautions.

HUMAN IMMUNODEFICIENCY VIRUS INFECTION

Human immunodeficiency virus (HIV) infection is caused by HIV, which is a retrovirus that causes immunosuppression. The viral infection causes the person to be susceptible to infections that would normally be controlled through immune responses. The term *HIV disease* is used interchangeably with HIV infection. With advances in treatment, HIV is managed as a chronic disease, since people are living longer.

Significance of Problem

HIV has caused a global pandemic and affected millions. In the past 30 years, important advances have been made in HIV prevention, testing, and treatment. In developed countries the result has been decreases in the number of HIV-related deaths, improved quality of life, and a significant decrease in the number of children born with HIV.[18]

More than 1 million people are currently living with HIV in the United States, with an estimated 50,000 new infections occurring annually. With the availability of effective treatment, people with HIV infection can live for a longer time, resulting in a dramatic drop in the number of deaths attributable to HIV.[19-21]

In North America HIV has been most prevalent among men who have sex with men. However, increasing numbers of new HIV infections are occurring in women, people of color, people who live in poverty, and adolescents. For the most part, HIV remains a disease of marginalized individuals: those who are disenfranchised by virtue of gender, race, sexual orientation, poverty, drug use, or lack of access to health care.[21,22]

Transmission of HIV

HIV can be transmitted as a result of contact with infected blood, semen, vaginal secretions, or breast milk. Transmission of HIV occurs through sexual intercourse with an infected partner; exposure to HIV-infected blood or blood products; and perinatal transmission during pregnancy, at delivery, or through breastfeeding.[19]

HIV-infected individuals can transmit HIV to others within a few days after becoming infected. The ability to transmit HIV continues for life. Transmission of HIV is subject to the same requirements as other microorganisms (i.e., a large enough amount of the virus must enter the body of a susceptible host).

Variables that influence whether infection will be established after an exposure include (1) duration and frequency of contact with the organism; (2) volume, virulence, and concentration of the organism; and (3) host immune status. The concentration of virus is an important variable. Large amounts of HIV can be found in the blood, and to a lesser extent in the semen, during the first 6 months of infection and again during the late stages of the disease (Fig. 15-1). Although unprotected sexual intercourse or blood exposure to an infected individual during these

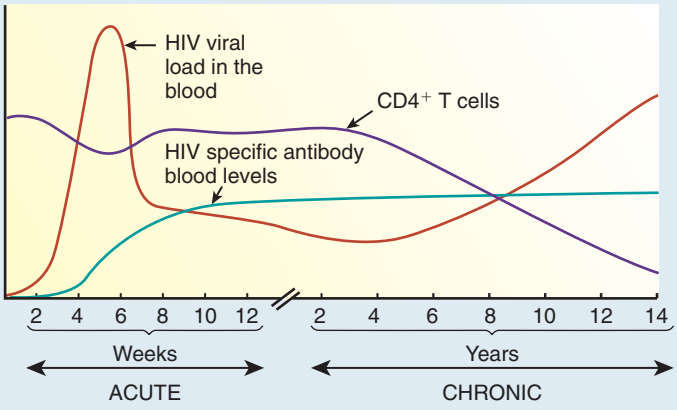

FIG. 15-1 Viral load in the blood in relationship to number of $CD4^+$ T cells over the spectrum of untreated HIV infection.

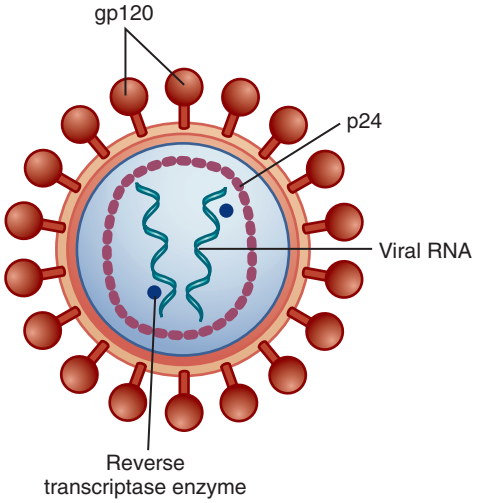

FIG. 15-2 HIV is surrounded by an envelope made up of proteins (including gp120) and contains a core of viral RNA and proteins.

periods is more risky, HIV can be transmitted during all phases of the disease.

HIV is not spread casually. The virus cannot be transmitted through hugging, dry kissing, shaking hands, sharing eating utensils, using toilet seats, or casual encounters in any setting.[19] It is not spread by tears, saliva, urine, emesis, sputum, feces, sweat, respiratory droplets, or enteric routes. Health care workers have a low risk of acquiring HIV at work, even after a needle-stick injury.[23]

Sexual Transmission. The most common mode of HIV transmission is unprotected sexual contact with an HIV-infected partner. Sexual activity involves contact with semen, vaginal secretions, and/or blood, all of which have lymphocytes that may contain HIV. During any form of sexual intercourse (anal, vaginal, or oral), the risk of infection is greater for the partner who receives the semen, although infection can also be transmitted to the inserting partner. This occurs because the receiver has prolonged contact with infected fluids, and it helps explain why it is easier to infect women than men during heterosexual intercourse. Sexual activities that cause trauma to local tissues can increase the risk of transmission. In addition, genital lesions from other sexually transmitted infections (e.g., herpes, syphilis) significantly increase the likelihood of transmission.

Contact With Blood and Blood Products. HIV can be transmitted during exposure to blood through drug-using equipment. Used equipment may be contaminated with HIV and other blood-borne organisms, and sharing that equipment can result in disease transmission.

In North America, transfusion of infected blood and blood products has caused only 1% of adult AIDS cases.[22] Routine screening of blood donors to identify at-risk individuals and testing donated blood for the presence of HIV have improved the safety of the blood supply. In countries that routinely test donated blood, HIV infection as a result of blood transfusions or hemophilia clotting factors is now unlikely.

Puncture wounds are the most common means of work-related HIV transmission. The risk of infection after a needle-stick exposure to HIV-infected blood is 0.3% to 0.4% (or 3 to 4 out of 1000).[23] The risk is higher if the exposure involves blood from a patient with a high level of circulating HIV, a deep puncture wound, a needle with a hollow bore and visible blood, a device used for venous or arterial access, or a patient who dies within 60 days. Splash exposures of blood on skin with an open lesion present some risk, but it is much lower than from a puncture wound.

Perinatal Transmission. Perinatal transmission from an HIV-infected mother to her infant can occur during pregnancy, delivery, or breastfeeding. On average, 25% of infants born to women with untreated HIV infection are born with HIV. Fortunately, the risk of transmission can be reduced to less than 2% in settings where pregnant women are routinely tested for HIV infection and, if found to be infected, treated with antiretroviral therapy (ART).[24]

Pathophysiology

HIV is an RNA virus. RNA viruses are called **retroviruses** because they replicate in a "backward" manner (going from RNA to DNA). Like all viruses, HIV cannot replicate unless it is inside a living cell. HIV enters a cell when the gp120 "knobs" (Fig. 15-2) on the viral envelope bind to specific CD4 and chemokine receptor sites on the cell's surface *(fusion)* (Fig. 15-3). Chemokine receptors are proteins normally found in cell membranes that respond to chemokines outside the cell and trigger a response inside the cell. HIV uses the chemokine receptors CXCR4 and CCR5 as co-receptors (CD4 is the main receptor) to support binding and entry into the $CD4^+$ T cell.[25]

Once bound, viral RNA enters the $CD4^+$ T cell, where it is transcribed into a single strand of viral DNA with the assistance of **reverse transcriptase,** an enzyme made by retroviruses. This strand copies itself, becoming double-stranded viral DNA, which then enters the cell's nucleus and, using another enzyme called **integrase,** splices itself into the human genome, becoming a permanent part of the cell's genetic structure. This action has two consequences: (1) because all genetic material is replicated during cell division, all daughter cells are also infected and (2) viral DNA in the genome directs the cell to make new HIV. HIV production in the cell starts with long strands of HIV RNA. These are cut into appropriate lengths in the presence of the enzyme **protease** during the budding sequence.[25]

Initial infection with HIV results in **viremia** (large amounts of virus in the blood). This is followed within a few weeks by a prolonged period in which HIV levels in the blood remain low even without treatment (see Fig. 15-1). During this time, which may last for more than 10 years, clinical symptoms can be

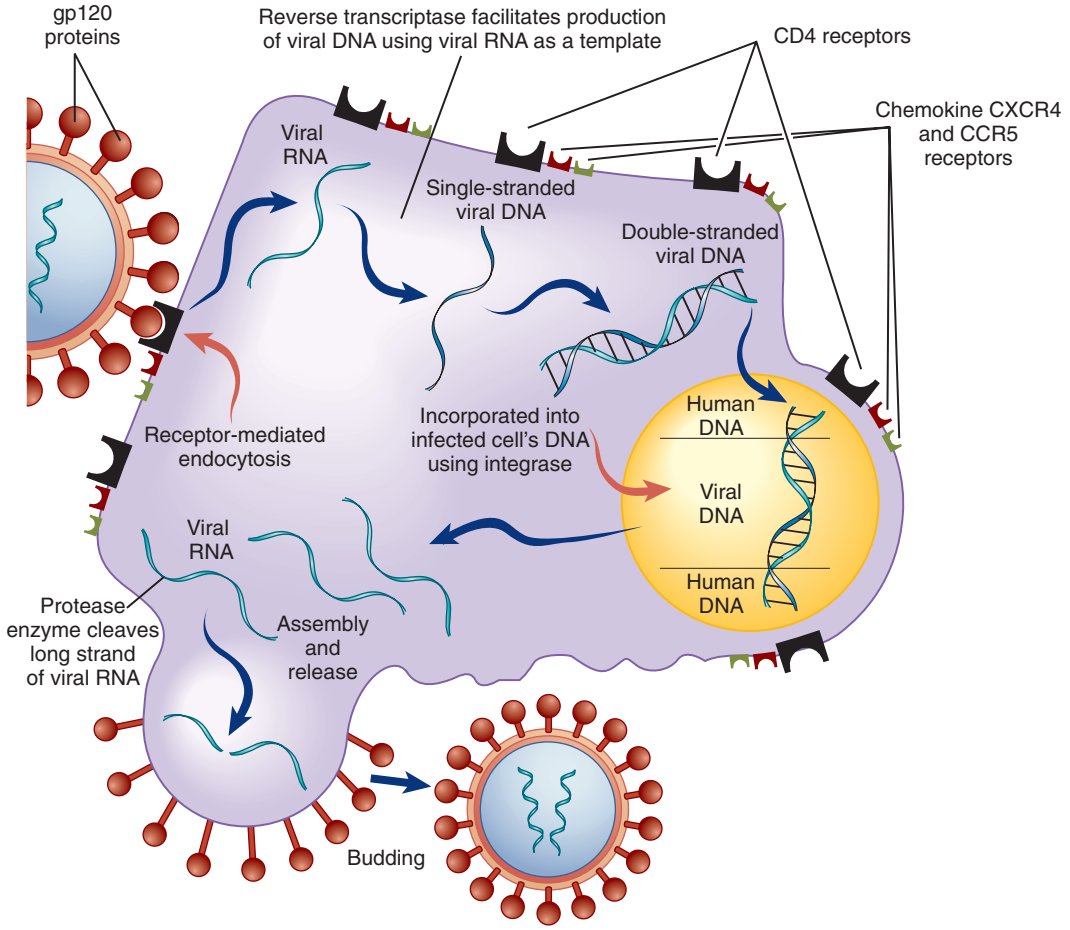

FIG. 15-3 HIV has gp120 glycoproteins that attach to CD4 and chemokine CXCR4 and CCR5 receptors on the surface of $CD4^+$ T cells. Viral RNA then enters the cell, produces viral DNA in the presence of reverse transcriptase, and incorporates itself into the cellular genome in the presence of integrase, causing permanent cellular infection and the production of new virions. New viral RNA develops initially in long strands that are cut in the presence of protease and leave the cell through a budding process that ultimately contributes to cellular destruction.

limited. Even without symptoms, HIV replication occurs at a rapid and constant rate in the blood and lymph tissues. A major consequence of rapid replication is that errors can occur in the copying process, causing mutations that can contribute to resistance to ART and limit treatment options.

In the initial stages of HIV infection, B cells and T cells respond and function normally. B cells make HIV-specific antibodies that are effective in reducing viral loads in the blood. Activated T cells mount a cellular immune response to viruses trapped in the lymph nodes.[25]

HIV infects human cells with CD4 receptors on their surfaces, including lymphocytes, monocytes/macrophages, astrocytes, and oligodendrocytes. However, immune dysfunction in HIV infection is predominantly the result of damage to and destruction of $CD4^+$ T cells (also known as T helper cells or $CD4^+$ T lymphocytes). These cells are targeted because they have more CD4 receptors on their surfaces than the other CD4 receptor–bearing cells. $CD4^+$ T cells play a key role in the immune system's ability to recognize and defend against pathogens.

Adults without immune dysfunction normally have 800 to 1200 $CD4^+$ T cells per microliter (μL) of blood. The normal life span of a $CD4^+$ T cell is about 100 days, but HIV-infected $CD4^+$ T cells die after an average of only 2 days.

HIV destroys about 1 billion $CD4^+$ T cells every day. The body can produce new $CD4^+$ T cells to replace the destroyed cells for many years. However, eventually the ability of HIV to destroy $CD4^+$ T cells exceeds the body's ability to replace the cells. The decline in the $CD4^+$ T cell count impairs immune function. Generally, the immune system remains healthy with more than 500 $CD4^+$ T cells/μL. Immune problems start to occur when the count drops below 500 $CD4^+$ T cells/μL. Severe problems develop with fewer than 200 $CD4^+$ T cells/μL. With HIV, a point is eventually reached where so many $CD4^+$ T cells have been destroyed that not enough are left to regulate immune responses (see Fig. 15-1). This allows **opportunistic diseases** (infections and cancers that occur in immunosuppressed patients) to develop. Opportunistic diseases are the main cause of disease, disability, and death in patients with HIV infection.

Clinical Manifestations and Complications

The typical course of untreated HIV infection follows the pattern shown in Fig. 15-4. It is important to remember that (1) disease progression is highly individualized, (2) treatment can significantly alter this pattern, and (3) an individual's prognosis is unpredictable.

Acute Infection. A mononucleosis-like syndrome of fever, swollen lymph glands, sore throat, headache, malaise, nausea,

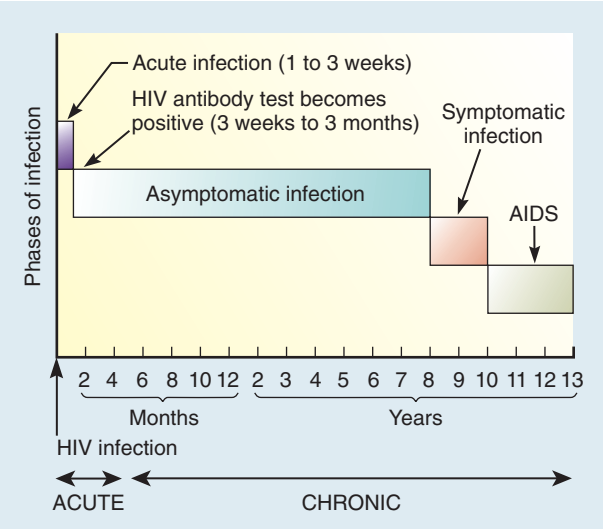

FIG. 15-4 Timeline for the spectrum of untreated HIV infection. The timeline represents the course of untreated illness from the time of infection to clinical manifestations of disease.

FIG. 15-5 Oral thrush involving hard and soft palate.

FIG. 15-6 Kaposi sarcoma (KS). The malignant vascular lesions of KS can appear anywhere on the skin surface or on internal organs. Lesions vary in size from pinpoint to large and may appear in a variety of shades.

muscle and joint pain, diarrhea, and/or a diffuse rash often accompanies **seroconversion** (when HIV-specific antibodies develop). Some people also develop neurologic complications, such as aseptic meningitis, peripheral neuropathy, facial palsy, or Guillain-Barré syndrome.

These symptoms, called *acute HIV infection,* generally occur within 2 to 4 weeks after the initial infection and last for 1 to 3 weeks, although some symptoms may persist for several months. During this time a high **viral load** (the amount of HIV circulating in the blood) is noted, and $CD4^+$ T cell counts fall temporarily but quickly return to baseline or near-baseline levels (see Fig. 15-1). Many people, including health care providers, mistake acute HIV symptoms for a bad case of the flu.[26]

Chronic HIV Infection

Asymptomatic Infection. The interval between untreated HIV infection and a diagnosis of AIDS is about 10 years. During this time, $CD4^+$ T cell counts remain above 500 cells/μL (normal or only slightly decreased), and the viral load in the blood is low. This phase has been referred to as *asymptomatic infection,* although fatigue, headache, low-grade fever, night sweats, *persistent generalized lymphadenopathy* (PGL), and other symptoms may be present.[27]

Because most of the symptoms during early infection are vague and nonspecific for HIV, people may not be aware that they are infected. During this time, infected people continue their usual activities, which may include high-risk sexual and drug-using behaviors. This is a public health problem because infected individuals can transmit HIV to others even though they have no symptoms. Personal health is also affected because people who do not know that they are infected have little reason to seek treatment and are less likely to make behavior changes that could improve the quality and length of their lives.

Symptomatic Infection. As the $CD4^+$ T cell count drops to 200 to 500 cells/μL and the viral load increases, HIV advances to a more active stage. Symptoms seen in earlier phases become worse, leading to persistent fever, frequent drenching night sweats, chronic diarrhea, recurrent headaches, and fatigue severe enough to interrupt normal routines. Other problems may include localized infections, lymphadenopathy, and nervous system manifestations.[27]

The most common infection associated with this phase of HIV infection is oropharyngeal candidiasis, or thrush (Fig. 15-5). *Candida* organisms rarely cause problems in healthy adults, but are more common in HIV-infected people. Other infections that can occur at this time include shingles (caused by the varicella-zoster virus); persistent vaginal candidal infections; outbreaks of oral or genital herpes; bacterial infections; and Kaposi sarcoma (KS), which is caused by human herpesvirus 8 (Fig. 15-6). *Oral hairy leukoplakia,* an Epstein-Barr virus infection that causes painless, white, raised lesions on the lateral aspect of the tongue (Fig. 15-7), is another indicator of disease progression.[28]

AIDS. A diagnosis of **acquired immunodeficiency syndrome (AIDS)** is made when an HIV-infected patient meets criteria established by the CDC.[29] These criteria occur when the immune system becomes severely compromised (Table 15-9). As the viral load increases, the absolute number and percentage of T cells decrease and the risk of developing opportunistic diseases increases.

Opportunistic diseases generally do not occur in the presence of a functioning immune system. Many infections, a variety of malignancies, wasting, and HIV-related dementia can occur in patients with immune impairment (Table 15-10).

FIG. 15-7 Oral hairy leukoplakia on the lateral aspect of the tongue.

TABLE 15-9 DIAGNOSTIC CRITERIA FOR AIDS

AIDS is diagnosed when an individual with HIV develops at least one of the following conditions:

1. $CD4^+$ T cell count drops below 200 cells/μL.
2. One of the following opportunistic infections (OIs):
   - *Fungal*: candidiasis of bronchi, trachea, lungs, or esophagus; *Pneumocystis jiroveci* pneumonia (PCP); disseminated or extrapulmonary coccidioidomycosis; disseminated or extrapulmonary histoplasmosis
   - *Viral*: cytomegalovirus (CMV) disease other than liver, spleen, or nodes; CMV retinitis (with loss of vision); herpes simplex with chronic ulcer(s) or bronchitis, pneumonitis, or esophagitis; progressive multifocal leukoencephalopathy (PML); extrapulmonary cryptococcosis
   - *Protozoal*: toxoplasmosis of the brain, chronic intestinal isosporiasis, chronic intestinal cryptosporidiosis
   - *Bacterial: Mycobacterium tuberculosis* (any site); any disseminated or extrapulmonary mycobacteria, including *Mycobacterium avium* complex (MAC) or *Mycobacterium kansasii;* recurrent pneumonia; recurrent *Salmonella* septicemia
3. One of the following opportunistic cancers:
   - Invasive cervical cancer
   - Kaposi sarcoma (KS)
   - Burkitt's lymphoma
   - Immunoblastic lymphoma
   - Primary lymphoma of the brain
4. Wasting syndrome. *Wasting* is defined as a loss of 10% or more of ideal body mass.
5. AIDS dementia complex (ADC).

Modified from Centers for Disease Control and Prevention: 1993 Revised classification system for HIV infection and expanded surveillance case definition for AIDS among adolescents and adults, 1993. Retrieved from *www.cdc.gov/mmwr/preview/mmwrhtml/rr5710a1.htm?s_cid=rr5710a1_e*.

Organisms that do not cause severe disease in people with functioning immune systems can cause debilitating, disseminated, and life-threatening infections during this stage. Several opportunistic diseases may occur at the same time, compounding the difficulties of diagnosis and treatment. Advances in HIV treatment have decreased the occurrence of opportunistic diseases.

Diagnostic Studies

Diagnosis of HIV Infection. Diagnosis of HIV infection is made by testing for HIV antibodies and/or antigen in the blood. HIV-antibody tests detect HIV-specific antibodies, but typically it takes several weeks after the infection before antibodies can be detected on a screening test (see Fig. 15-1). This delay is known as the **window period.**

Standard antibody tests can be completed on blood or oral fluid specimens. They are sent to a laboratory, and results are reported back to the provider anywhere from a day to a week later. *Rapid* HIV-antibody tests are done in the office, and results can be shared with patients before they leave the office. They can also be done at home using a self-administered HIV test kit. A positive antibody test should be followed by a confirming test (usually the Western blot) (Table 15-11).

Laboratory Studies in HIV Infection. The progression of HIV infection is monitored by two important laboratory assessments: $CD4^+$ T cell counts and viral load. $CD4^+$ T cell counts provide a marker of immune function. As the disease progresses, the number of $CD4^+$ T cells usually decreases (see Fig. 15-1). The normal range for $CD4^+$ T cells is 800 to 1200 cells/μL. Laboratory tests that measure viral levels provide an assessment of disease progression. The lower the viral load, the less active the disease. In HIV, viral loads are reported as real numbers (e.g., 1260 copies/μL) or as undetectable. "Undetectable" indicates that the viral load is lower than the test is able to report. "Undetectable" does *not* mean that the virus has been eliminated from the body or that the individual can no longer transmit HIV to others.

Abnormal blood test results are common in HIV infection and may be caused by HIV, opportunistic diseases, or complications of therapy. Decreased white blood cell (WBC) counts, especially below-normal numbers of lymphocytes (lymphopenia) and neutrophils (neutropenia), are often seen. Low platelet counts (thrombocytopenia) may be caused by HIV, antiplatelet antibodies, or drug therapy. Anemia is associated with the chronic disease process and with adverse effects of ART. Altered liver function, caused by HIV infection, drug therapy, or co-infection with a hepatitis virus, is common. Early identification of co-infection with hepatitis B virus (HBV) or hepatitis C virus (HCV) is extremely important because these infections have a more serious course in patients with HIV, may ultimately limit options for ART, and can cause liver-related morbidity and mortality.[27]

Two types of resistance tests can determine if a patient's HIV is resistant to drugs used for ART. The *genotype assay* detects drug-resistant viral mutations that are present in reverse transcriptase and protease genes. The *phenotype assay* measures the growth of HIV in various concentrations of antiretroviral drugs (much like bacteria-antibiotic sensitivity tests). These assays help determine new drug combinations for patients who are not responding to therapy.

Collaborative Care

Collaborative care of the HIV-infected patient focuses on (1) monitoring HIV disease progression and immune function, (2) initiating and monitoring ART, (3) preventing the development of opportunistic diseases, (4) detecting and treating opportunistic diseases, (5) managing symptoms, (6) preventing or decreasing complications of treatment, and (7) preventing further transmission of HIV. To accomplish these objectives, ongoing assessment, clinician-patient interactions, and patient teaching and support are required.

The initial patient visit provides an opportunity to gather baseline data and to start establishing rapport. A complete history and physical examination, including an immunization history and psychosocial and dietary evaluations, should be

TABLE 15-10 OPPORTUNISTIC DISEASES ASSOCIATED WITH HIV INFECTION*

Organism or Disease	Clinical Manifestations
Candida albicans	Thrush (see Fig. 15-5), esophagitis, vaginitis; whitish yellow patches in mouth, esophagus, GI tract, vagina
Coccidioides immitis	Pneumonia and fever, weight loss, cough
CNS lymphoma	Cognitive dysfunction, motor impairment, aphasia, seizures, personality changes, headache
Cryptococcus neoformans	Meningitis, cognitive impairment, motor dysfunction, fever, seizures, headache
Cryptosporidium muris	Gastroenteritis, watery diarrhea, abdominal pain, weight loss
Cytomegalovirus (CMV)	*Retinitis:* retinal lesions, blurred vision, loss of vision *Esophagitis, stomatitis:* difficulty swallowing; colitis or gastritis: bloody diarrhea, pain, weight loss *Pneumonitis:* respiratory symptoms *Neurologic disease:* CNS manifestations
Hepatitis B virus (HBV)	Jaundice, fatigue, abdominal pain, loss of appetite, nausea, vomiting, joint pain; 30% may have no signs or symptoms
Hepatitis C virus (HCV)	Jaundice, fatigue, abdominal pain, loss of appetite, nausea, vomiting, dark urine; 80% may have no signs or symptoms
Herpes simplex	*HSV-1 (type 1):* orolabial and mucocutaneous vesicular and ulcerative lesions; keratitis; visual disturbances; encephalitis; CNS manifestations *HSV-2 (type 2):* genital and perianal vesicular and ulcerative lesions
Histoplasma capsulatum	*Pneumonia:* fever, cough, weight loss *Meningitis:* CNS manifestations, disseminated disease
Influenza virus	Fever (usually high), headache, extreme tiredness, dry cough, sore throat, runny or stuffy nose, muscle aches; nausea, vomiting, and diarrhea can occur
JC papovavirus	Progressive multifocal leukoencephalopathy (PML), CNS manifestations, mental and motor declines
Kaposi sarcoma (KS) caused by human herpesvirus 8 (HHV-8)	Vascular lesions on the skin (see Fig. 15-6), mucous membranes, and viscera with wide range of presentation: firm, flat, raised, or nodular; pinpoint to several cm in size; hyperpigmented, multicentric; can cause lymphedema and disfigurement, particularly when confluent; usually not serious unless occurring in the respiratory or gastrointestinal system
***Mycobacterium avium* complex (MAC)**	Gastroenteritis, watery diarrhea, weight loss
***Mycobacterium tuberculosis* (MTB, TB)**	Respiratory and disseminated disease; productive cough, fever, night sweats, weight loss
***Pneumocystis jiroveci* pneumonia (PCP)**	Pneumonia, nonproductive cough, hypoxemia, progressive shortness of breath, fever, night sweats, fatigue
Toxoplasma gondii	Encephalitis, cognitive dysfunction, motor impairment, fever, altered mental status, headache, seizures, sensory abnormalities
Varicella zoster virus (VZV)	*Shingles:* erythematous maculopapular rash along dermatomal planes, pain, pruritus *Ocular:* progressive outer retinal necrosis (PORN)

*Treatment of opportunistic diseases is presented in eTable 15-2 on the website for this chapter.

TABLE 15-11 HIV-ANTIBODY TESTS

1. A highly sensitive enzyme immunoassay (EIA) is done to detect serum antibodies that bind to HIV antigens on test plates. Blood samples that are negative on this test are reported as negative.
   - If the patient reports recent risky behaviors, encourage retesting at 3 wk, 6 wk, and 3 mo.
2. If the blood is EIA-antibody positive, repeat the test.
3. If the blood is repeatedly EIA-antibody positive, a more specific confirming test, such as the Western blot (WB) or immunofluorescence assay (IFA), is done.
4. Blood that is reactive in all of the first three steps is reported as HIV-antibody positive.
5. If the results are indeterminate, the following steps are taken:
   - If in-depth risk assessment reveals that the individual does not have a history of high-risk activities, reassure the patient that HIV infection is extremely unlikely and suggest retesting in 3 mo.
   - If in-depth risk assessment reveals that the individual does have a history of high-risk activities, consider tests that detect HIV antigen.

Rapid HIV-Antibody Testing

1. Rapid testing is strongly recommended by the Centers for Disease Control and Prevention. Results are highly accurate, and it can be done in a variety of settings (mobile health units, physicians' offices, or even in the privacy of an individual's home). Results are typically available within 20 min.
2. In-home use HIV test kits are available. Testing is done on an oral fluid sample.
3. Rapid tests are screening tests for antibodies, not for antigen.
4. Negative rapid tests should be followed by a risk assessment to determine the need for repeat tests.
5. Positive rapid tests can be disclosed to the patient, but need to be confirmed with the more specific WB or IFA (as above). This step necessitates a blood draw and a return appointment to get results.

Combined Antibody/Antigen Testing

1. The combined antibody/antigen test allows for diagnosis of HIV infection, especially during the window period when antibody may be undetectable but viral loads are generally high.

conducted. Findings from the history, assessment, and laboratory tests help to determine patient needs. This is also a good time to complete the case reports required by the state health department. Patient teaching about the spectrum of HIV disease, treatment, prevention of transmission to others, improvements in health, and family planning can be initiated at this meeting. Use patient input to develop a plan of care and determine the need for referrals. Remember that a newly diagnosed patient may not be able to retain or understand information. Be prepared to repeat and clarify information over the course of several months.

Drug Therapy for HIV Infection. The goals of drug therapy in HIV infection are to (1) decrease the viral load, (2) maintain or increase $CD4^+$ T cell counts, (3) prevent HIV-related symptoms and opportunistic diseases, (4) delay disease progression, and (5) prevent HIV transmission. HIV cannot be cured, but **antiretroviral therapy (ART)** can delay disease progression by decreasing viral replication. When taken consistently and correctly, ART can reduce viral loads by 90% to 99%, which makes adherence to treatment regimens extremely important.

Drugs used to treat HIV work at various points in the HIV replication cycle (Table 15-12). The major advantage of using drugs from different classes is that combination therapy can inhibit viral replication in several different ways, making it more difficult for the virus to recover and decreasing the likelihood of drug resistance. A major problem with most drugs used in ART is that resistance develops rapidly when they are used alone *(monotherapy)* or taken in inadequate doses.[27,28] For that reason, combinations of three or more drugs should be used.

Many antiretroviral drugs have dangerous and potentially lethal interactions with other commonly used drugs, including over-the-counter drugs and herbal therapies. For example, St. John's wort, an herb used to alleviate depression, can interfere with ART. Encourage patients to discuss the use of all over-the-counter and herbal products with their health care providers.

TABLE 15-12 DRUG THERAPY

HIV Infection

Drug Classification	Mechanism of Action	Examples*
Entry Inhibitors	Prevent binding of HIV to cells, thus preventing entry of HIV into cells where replication would occur	enfuvirtide (Fuzeon) maraviroc (Selzentry)
Reverse Transcriptase Inhibitors		
Nucleoside Reverse Transcriptase Inhibitors (NRTIs)	Insert a piece of DNA into the developing HIV DNA chain, blocking further development of the chain and leaving the production of the new strand of HIV DNA incomplete	zidovudine (AZT, ZDV, Retrovir) didanosine (ddI, Videx, Videx-EC [time-released]) stavudine (d4T, Zerit) lamivudine (3TC, Epivir) abacavir (Ziagen) emtricitabine (FTC, Emtriva)
Nonnucleoside Reverse Transcriptase Inhibitors (NNRTIs)	Inhibit the action of reverse transcriptase	nevirapine (Viramune) delavirdine (Rescriptor) efavirenz (Sustiva) etravirine (Intelence) rilpivirine (Edurant)
Nucleotide Reverse Transcriptase Inhibitor (NtRTI)	Combines with reverse transcriptase enzyme to block the process needed to convert HIV RNA into HIV DNA	tenofovir (Viread)
Integrase Inhibitors	Bind with integrase enzyme and prevent HIV from incorporating its genetic material into the host cell	raltegravir (Isentress) elvitegravir† dolutegravir (Tivicay)
Protease Inhibitors (PIs)	Prevent the protease enzyme from cutting HIV proteins into the proper lengths needed to allow viable virions to assemble and bud out from the cell membrane	saquinavir (Fortovase, Invirase) indinavir (Crixivan) ritonavir (Norvir)‡ nelfinavir (Viracept) atazanavir (Reyataz) fosamprenavir (Lexiva) tipranavir (Aptivus) darunavir (Prezista) lopinavir + ritonavir (Kaletra)
Fixed-Dose Combination Products	More than one drug combined into a single tablet. Drugs may be from the same or different classes.	Atripla (tenofovir DF + emtricitabine + efavirenz) Combivir (lamivudine + zidovudine) Complera (tenofovir DF + emtricitabine + rilpivirine) Epzicom (abacavir + lamivudine) Trizivir (abacavir + lamivudine + zidovudine) Truvada (tenofovir DF + emtricitabine) Stribild (tenofovir DF + emtricitabine + elvitegravir + cobicistat§)

*Side effects of these drugs are listed in eTable 15-3 available on the website for this chapter.
†Part of the combination pill Stribild (see below)
‡Most often used in low doses with other PIs to boost effect.
§Cobicistat is a pharmacologic booster that enhances the potency of some HIV antiretrovirals. It has no direct effects against HIV.
DF, Disoproxil fumarate.

DRUG ALERT: Efavirenz (Sustiva)

- Do not use in pregnancy, because large doses could cause fetal anomalies.
- Once-a-day doses should be taken at bed time (at least initially) to help patients cope with side effects, including dizziness and confusion.
- Inform patients that many people who use the drug have reported vivid and sometimes bizarre dreams.

Drug Therapy for Opportunistic Diseases. Management of HIV is complicated by the many opportunistic diseases that can develop as the immune system deteriorates (see Table 15-10). Prevention is the preferred approach to opportunistic diseases. A number of opportunistic diseases associated with HIV can be delayed or prevented with adequate ART, vaccines (including hepatitis B, influenza, and pneumococcal), and disease-specific prevention measures. Although it is usually not possible to eradicate opportunistic diseases once they occur, prophylactic medications can significantly decrease morbidity and mortality rates.[30] Advances in the prevention, diagnosis, and treatment of opportunistic diseases have contributed significantly to increased life expectancy. (Drug therapy for opportunistic infections is presented in eTable 15-2 on the website for this chapter.)

Preventing Transmission of HIV. Preexposure prophylaxis (PrEP) is a comprehensive HIV prevention strategy to reduce the risk of sexually acquired HIV infection in adults at high risk.[31] PrEP includes safe sex practices, risk reduction counseling, and regular HIV testing. In addition, emtricitabine and tenofovir (Truvada) can be used for PrEP.

Truvada is the first drug approved to reduce the risk of HIV infection in uninfected individuals who are at high risk of HIV infection and who may engage in sexual activity with HIV-infected partners. Truvada is also currently used in combination with other antiretroviral agents for the treatment of HIV-infected people. Guidelines for PrEP for HIV prevention are available at *www.cdc.gov/hiv/prep/pdf/PrEPfactsheet.pdf*.

NURSING MANAGEMENT HIV INFECTION

NURSING ASSESSMENT

Nursing assessment for individuals not known to be infected with HIV should focus on behaviors that put the person at risk for HIV and other sexually transmitted and blood-borne infections. Assess patients for risky behaviors on a regular basis. Do not assume that someone is without risk because he or she is too old or too young, is married, or sings in the church choir.

Help individuals assess risk by asking some basic questions: (1) Have you ever had a blood transfusion or used clotting factors? If so, was it before 1985? (2) Have you ever shared drug-using equipment with another person? (3) Have you ever had a sexual experience in which your penis, vagina, rectum, or mouth came into contact with another person's penis, vagina, rectum, or mouth? and (4) Have you ever had a sexually transmitted infection? These questions provide the minimum information needed to initiate a risk assessment. A positive response to any of these questions should be followed by an in-depth exploration of issues related to the identified risk.

Specific assessments are needed for an individual who has been diagnosed with HIV infection. Subjective and objective data that should be obtained are presented in Table 15-13. Repeated nursing assessments over time are essential because people's circumstances change. Early recognition and treatment can slow the progression of HIV infection and prevent new infections. A complete history and thorough systems review can help identify and address problems in a timely manner.

PLANNING

Nursing interventions can help the patient (1) adhere to drug regimens; (2) adopt a healthy lifestyle that includes avoiding exposure to other sexually transmitted infections and blood-borne diseases; (3) protect others from HIV; (4) maintain or develop healthy and supportive relationships; (5) maintain activities and productivity; (6) explore spiritual issues; (7) come to terms with issues related to disease, disability, and death; and (8) cope with symptoms caused by HIV and its treatments.

NURSING IMPLEMENTATION

The complexity of HIV disease is related to its chronic nature. As with most chronic and infectious diseases, primary preven-

ETHICAL/LEGAL DILEMMAS

Individual Versus Public Health Protection

Situation

A nurse in a community clinic is having a follow-up visit with V.T., a 38-year-old woman, who was found to have HIV during her annual examination 2 wk ago. During the visit, V.T. discloses that she has been verbally and physically abused by her partner. V.T. also indicates that she had not yet told her partner about the HIV diagnosis because she is afraid that he will hurt her. She has not used any protection during sex with him since she learned of her test results because she suspects he infected her.

Ethical/Legal Points for Consideration

- You face a conflict between preventing further harm to V.T. (possible increase in intimate partner violence), providing care to her partner (his need for an HIV test, diagnosis, and treatment), and protecting the public health (potential spread of HIV infection to her partner or from her partner to others in the community). Patient teaching and support are paramount because your primary obligation is to the patient.
- Because relevant law varies from state to state, your first step is to be familiar with your state law concerning mandated reporting for domestic partner abuse and infectious diseases.
- Laws regarding protection of privacy in HIV testing are federal and apply everywhere.
- In many states, reporting domestic abuse is mandatory only when the abuse is actually witnessed by the reporter or when the immediate effects of the abuse (e.g., wounds, contusions, broken bones) are witnessed.
- You should be familiar with crisis counseling services for V.T. and offer her the following advice: collect and stash a set of car keys or taxi money in a safe place, keep a bag packed and hidden or even stored in a locker somewhere accessible, develop a code phrase to use with a friend or family member to call for help, keep a cell phone charged and hidden with the money.

Discussion Questions

1. Within the parameters of your state's requirements for reportable conditions, how can you protect the patient's confidentiality to prevent further intimate partner violence?
2. What services are offered by your state to notify a partner without disclosing the source patient's name? How would V.T. access those services in your state?
3. How can you protect the partner from possible infection while also protecting V.T. from further violence?
4. How can you best address the issue of intimate partner violence? What resources would V.T. have in your community?
5. Discuss the benefits of universal, voluntary testing in light of V.T.'s case.

tion and health promotion are the most effective health care strategies. When prevention fails, disease results. Table 15-14 presents a synopsis of nursing goals, assessments, and interventions at each stage of HIV infection.

HEALTH PROMOTION. Even with recent successes in HIV treatment, prevention is the only way to eventually control the epidemic. In addition, health promotion encourages early detection of the disease so that, if primary prevention has failed, early intervention can be initiated.

Prevention of HIV Infection. HIV infection is preventable. Avoiding or modifying risky behaviors is the most effective prevention tool.[32] Nursing interventions to prevent disease transmission are based on an assessment of the individual's risky behaviors. Although changing behaviors is difficult, encourage the patient to adopt safer, healthier, and less risky behaviors. Provide culturally sensitive, language appropriate, and age-specific teaching and behavior change counseling. Nurses who are comfortable with and know how to talk about

HEALTHY PEOPLE

Prevention and Early Detection of HIV

- Increase safe sexual practices, including condom use.
- Decrease equipment sharing among IV drug users.
- Increase clinician skills to assess for risk factors for HIV infection, recommend HIV testing, and provide counseling for behavior change.
- Make voluntary HIV testing a routine part of health care.
- Increase access to new HIV testing technologies, especially rapid testing.
- Increase access to HIV testing facilities in traditional health care settings, as well as in alternative sites such as drug and alcohol treatment facilities and community-based organizations.
- Increase risk assessment and individualized behavior change messages to people with HIV to prevent new infections.
- Decrease perinatal HIV infection by offering voluntary HIV testing as a part of routine prenatal care.
- Provide counseling and appropriate HIV therapy to those who are infected.

TABLE 15-13 NURSING ASSESSMENT

HIV-Infected Patient

Subjective Data

Important Health Information

Past health history: Route of infection; hepatitis; other sexually transmitted infections; tuberculosis; frequent viral, fungal, and/or bacterial infections

Medications: Use of immunosuppressive drugs

Functional Health Patterns

Health perception–health management: Perception of illness; alcohol and drug use; malaise

Nutritional-metabolic: Weight loss, anorexia, nausea, vomiting; lesions, bleeding, or ulcerations of lips, mouth, gums, tongue, or throat; sensitivity to acidic, salty, or spicy foods; difficulty swallowing; abdominal cramping; skin rashes, lesions, or color changes; wounds that don't heal

Elimination: Persistent diarrhea, change in character of stools; painful urination, low back pain

Activity-exercise: Chronic fatigue, muscle weakness, difficulty walking; cough, shortness of breath

Sleep-rest: Insomnia, night sweats, fatigue

Cognitive-perceptual: Headaches, stiff neck, chest pain, rectal pain, retrosternal pain; blurred vision, photophobia, diplopia, loss of vision; hearing impairment; confusion, forgetfulness, attention deficit, changes in mental status, memory loss, personality changes; paresthesias, hypersensitivity in feet, pruritus

Role-relationship: Support system(s), career or job, financial resources

Sexuality-reproductive: Lesions on genitalia (internal or external), pruritus or burning in vagina, penis, or anus; painful sexual intercourse, rectal pain or bleeding, changes in menstruation, vaginal or penile discharge; use of birth control measures, pregnancies, desire for future children

Coping–stress tolerance: Stress levels, previous losses, coping patterns, self-concept; social withdrawal

Objective Data

General

Lethargy, persistent fever, lymphadenopathy, peripheral wasting, fat deposits in truncal areas and upper back

Integumentary

Decreased skin turgor, dry skin, diaphoresis; pallor, cyanosis; lesions, eruptions, discolorations, bruises of skin or mucous membranes; vaginal or perianal excoriation; alopecia; delayed wound healing

Eyes

Presence of exudates, retinal lesions or hemorrhage, papilledema

Respiratory

Tachypnea, dyspnea, intercostal retractions; crackles, wheezing, productive or nonproductive cough

Cardiovascular

Pericardial friction rub, murmur, bradycardia, tachycardia

Gastrointestinal

Mouth lesions, including blisters (HSV), white-gray patches (*Candida* infection), painless white lesions on lateral aspect of the tongue (hairy leukoplakia), discolorations (KS); gingivitis, tooth decay or loosening; redness or white patchy lesions of throat; vomiting, diarrhea, incontinence; rectal lesions; hyperactive bowel sounds, abdominal masses, hepatosplenomegaly

Musculoskeletal

Muscle wasting, weakness

Neurologic

Ataxia, tremors, lack of coordination; sensory loss; slurred speech, aphasia; memory loss, peripheral neuropathy, apathy, agitation, depression, inappropriate behavior; decreasing levels of consciousness, seizures, paralysis, coma

Reproductive

Genital lesions or discharge, abdominal tenderness secondary to pelvic inflammatory disease (PID)

Possible Diagnostic Findings

Positive HIV antibody assay (EIA, confirmed by WB or IFA); detectable viral load; ↓ $CD4^+$ T cell count, ↓ WBC count, lymphopenia, anemia, thrombocytopenia; electrolyte imbalances; abnormal liver function tests; ↑ cholesterol, triglycerides, and blood glucose

EIA, Enzyme immunoassay; *HSV,* herpes simplex virus; *IFA,* immunofluorescence assay; *KS,* Kaposi sarcoma; *WB,* Western blot; *WBC,* white blood cell.

TABLE 15-14 PATIENT & CAREGIVER TEACHING GUIDE

Antiretroviral Drugs

Resistance to antiretroviral drugs is a major problem in treating HIV infection. Include the following instructions when teaching the patient and/or caregiver to decrease the risk of developing resistance.

1. Discuss options with your health care provider to find the best regimen for you. Your provider should order at least three different antiretroviral drugs from at least two different drug groups.
2. Know the drugs you are taking and how to take them (some have to be taken with food, some must be taken on an empty stomach, some cannot be taken together). If you do not understand, ask. Have your nurse write the instructions clearly for you.
3. Take the full dose prescribed, and take it on schedule. If you cannot take the drug because of side effects or other problems, report it to your health care provider immediately.
4. Take all of your medications as prescribed. Do not quit taking one drug while continuing the others. If you cannot tolerate even one of your drugs, talk to your health care provider, who will recommend a way to deal with the side effects or a new set of drugs.
5. Many antiretroviral drugs interact with other drugs, including a number of common drugs you can buy without a prescription. Be sure your health care provider and pharmacist know all of the drugs that you are taking, and do not take any new drugs without checking for possible interactions.
6. The goals of antiretroviral therapy are to decrease the amount of virus in your blood (your viral load) and to keep your $CD4^+$ T cell count high. The best results reduce your viral load below detectable levels and keep your $CD4^+$ T cell count high. Most health care providers do routine laboratory work every 3 to 6 mo whether you are taking antiretroviral agents or not.
7. Two to 4 wk after you start on drug therapy (or change your therapy), your health care provider will test your viral load to find out how the drugs are working.
   - Your viral load is reported in absolute numbers or in logarithms (a mathematical concept). All you need to know is that you want to see the viral load drop. If reports are in logarithms, you want to see a drop of at least 1 unit, which means that 90% of your viral load has been eliminated. If your viral load drops by 2 units, your viral load will have decreased by 95%. If your viral load drops by 3 units, your viral load will have decreased by 99%.
   - Your $CD4^+$ T cell count is reported in absolute numbers or percentages. It is best for your $CD4^+$ T cell count to be above 500 to 600 cells/μL. If reported in percentages, you would like your $CD4^+$ T cell value to be above 14%.
8. An undetectable viral load means that the amount of virus is extremely low and HIV cannot be found in the blood using current testing technology. It does not mean that the virus is gone because the virus can be in lymph nodes and organs that blood tests cannot detect. It also does not mean that you are no longer able to transmit HIV to others. You will need to continue protecting all of your sexual and drug-using partners from HIV.

EVIDENCE-BASED PRACTICE

Applying the Evidence

As a nurse in an HIV clinic, you are counseling P.S., a 25-year-old gay man, and his partner. P.S. is on antiretroviral therapy. His viral load is very low, and his $CD4^+$ T cell count is normal. He tells you that since the medications are working, he and his partner (who is not infected with HIV) have decided to forgo the use of condoms. They tell you that they are in a committed relationship and have no other partners. You spend time explaining to both of them the risks of unprotected sex: his partner may get infected with HIV even with a low viral load (although the risk is decreased).

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
One of the best ways to prevent HIV transmission from an infected person to an uninfected person is by using condoms.	You know that risk-reducing sexual activities in this situation include the continued use of condoms. However, you also know that a very low viral load decreases the risk of HIV transmission.	After listening, the patient tells you that he and his partner do not like using condoms. They both understand the risks and believe that while the medications are working, the risk is low and worth it.

Your Decision and Action

As his nurse, you respect his decision. You remind him of the importance of maintaining his medication regimen and attending his appointments at the clinic. You explain that this will be even more important now to keep P.S.'s infection under control.

Reference for Evidence

Cohen MS, McCauley M, Gamble RT: HIV treatment as prevention and HPTN 052, *Curr Opin HIV AIDS* 7(2):99, 2012.

sensitive topics such as sexuality and drug use are best prepared to provide prevention teaching.

A wide variety of activities can reduce the risk of HIV infection. Individuals will choose the methods that best fit their needs and circumstances. Prevention techniques can be divided into *safe sexual activities* (those that eliminate risk) and *risk-reducing sexual activities* (those that decrease, but do not eliminate, risk).

The goal is to develop safer, healthier, and less risky behaviors. The more consistently and correctly prevention methods are used, the more effective they are in preventing HIV infection. It is also a good idea to use a combination of prevention methods (e.g., using condoms and decreasing the number of sex partners) to increase the prevention effect.

Decreasing Risks Related to Sexual Intercourse. *Safe sexual activities* eliminate the risk of exposure to HIV in semen and vaginal secretions.[33] Abstaining from all sexual activity is an effective way to accomplish this goal, but there are safe options for those who cannot or do not wish to abstain. Limiting sexual behavior to activities in which the mouth, penis, vagina, or rectum does not come into contact with a partner's mouth, penis, vagina, or rectum eliminates contact with blood, semen, or vaginal secretions. Safe activities include masturbation, mutual masturbation ("hand job"), and other activities that meet the "no contact" requirements. *Insertive sex* between partners who are not infected with HIV and not at risk of becoming infected with HIV is also considered safe.

Risk-reducing sexual activities decrease the risk of contact with HIV through the use of barriers. Barriers should be used when engaging in insertive sexual activity (oral, vaginal, or anal) with a partner who has HIV or whose HIV status is not known. The most commonly used barrier is the male condom. The *efficacy* (protection provided under ideal circumstances) of male condoms is essentially 100%. Their *effectiveness* (protection provided in actual or "real life" circumstances) is better than 90%. Male condoms can be used for protection during anal, vaginal, and oral intercourse. (The proper use and placement of the male condom are presented in eTable 15-4 on the website for this chapter.)

Female condoms provide an alternative to male condoms. Female condom efficacy is also close to 100%, and effectiveness

INFORMATICS IN PRACTICE

Use of Internet and Mobile Devices to Manage HIV

- The Internet offers resources and support for patients that can assist them in coping with their illness and educate them about signs and symptoms of serious illness.
- By monitoring their health and quickly spotting warning signs of serious illnesses, patients are able to alert their physicians and receive earlier treatment.
- These systems can help the patient manage antiretroviral therapy by sending medication reminders by text or e-mail.

is 94% to 97% against HIV and other sexually transmitted infections. (The proper use and placement of the female condom are presented in eTable 15-5 on the website for this chapter.) In addition, squares of latex (known as dental dams) can be used to cover the external female genitalia during oral sexual activity.

Decreasing Risks Related to Drug Use. Drug use, including alcohol and tobacco, is harmful. It can cause immunosuppression, poor nutrition, and a host of psychosocial problems, but drug use does not cause HIV infection. The major risk for HIV related to using drugs involves sharing equipment or having unsafe sexual experiences while under the influence of drugs. Basic risk reduction rules are (1) do not use drugs; (2) if you use drugs, do not share equipment; and (3) do not have sexual intercourse when under the influence of any drug (including alcohol) that impairs decision making.[34]

The safest method is to abstain from drugs, but this may not be a viable option for users who are not prepared to quit or have no access to drug treatment services. The risk of HIV for these individuals can be eliminated if they do not share equipment. Injecting equipment ("works") includes needles, syringes, cookers (spoons or bottle caps used to mix the drug), cotton, and rinse water. Equipment used to snort (straws) or smoke (pipes) drugs can also be contaminated with blood and should not be shared.

Access to sterile equipment is an important risk elimination tactic. Some communities have needle and syringe exchange programs (NSEPs) that provide sterile equipment in exchange for used equipment. Opposition to these programs is related to the fear that access to injecting supplies will increase drug use. However, studies have shown that, in communities with NSEPs, drug use does not increase, rates of HIV and other blood-borne infections are controlled, and an overall cost benefit results.[35] Cleaning equipment before use can also reduce risk by decreasing the chance of blood contact. (The proper use of drug equipment is presented in eTable 15-6 on the website for this chapter.)

Decreasing Risks of Perinatal Transmission. The best way to prevent HIV infection in infants is to prevent HIV infection in women. Women who are already infected with HIV should be asked about their reproductive desires. Those who choose not to have children need to have family planning methods discussed in detail. Should they become pregnant, abortion may be desired and should be discussed in conjunction with other options, including the possibility of maintaining the pregnancy and using ART to decrease the risk of transmission. If HIV-infected pregnant women are appropriately treated during pregnancy, the rate of perinatal transmission can be decreased from 25% to less than 2%.[24] ART has significantly decreased the risk for infants born to HIV-infected women, and more of these women are now becoming mothers. The current standard of care is for all women who are pregnant or contemplating pregnancy to be counseled about HIV, routinely offered access to voluntary HIV-antibody testing, and, if infected, offered optimal ART.[24]

Decreasing Risks at Work. The risk of infection from occupational exposure to HIV is small but real. OSHA requires employers to protect workers from exposure to blood and other potentially infectious materials (see Table 15-8). Precautions and safety devices decrease the risk of direct contact with blood and body fluids. Should exposure to HIV-infected fluids occur, **postexposure prophylaxis (PEP)** with combination ART can significantly decrease the risk of infection.[23] The need for timely treatment and counseling makes it even more critical for nurses to report all blood exposures.

HIV Testing. An estimated 21% of people living with HIV in the United States are not aware that they are infected. People who do not know they are infected are more likely to transmit the infection to others.[36,37] The CDC recommends universal, voluntary testing for all people ages 13 to 64 regardless of the patient's risk or perceived risk. The CDC recommends an "opt out" process in which the patient is given the opportunity to decline a test, but it is offered as "routine." The goal is to normalize the test, decrease the stigma related to HIV testing, find hidden cases, get infected individuals into care, and prevent new cases of infection.[38]

ACUTE INTERVENTION

Early Intervention. Early intervention after detection of HIV infection can promote health and limit disability. The nursing assessment in HIV disease should focus on early detection of symptoms, opportunistic diseases, and psychosocial problems[39] (see Tables 15-13 and eTable 15-7).

Initial Response to Diagnosis of HIV. Reactions to an HIV diagnosis are similar to the reactions of people who are diagnosed with any life-threatening, debilitating, or chronic illness. They include anxiety, panic, fear, depression, denial, hopelessness, anger, and guilt.[40] Unfortunately, all these emotions are overlaid with the stigma and discrimination that continue to pervade societal reactions to HIV. Many of these reactions are also seen in the patient's family members, friends, and caregivers. As time passes, patients and their loved ones will be confronted with complex treatment decisions; feelings of loss, anger, powerlessness, depression, and grief; social isolation; the possibility of death; and/or thoughts of suicide.

Antiretroviral Therapy. ART can significantly slow the clinical progression of HIV.[28] However, treatment regimens can be complex, the drugs have side effects, ART does not work for everyone, and it is expensive. These factors can contribute to problems with adherence to treatment, a dangerous situation because of the high risk of developing drug resistance.

As a nurse, you are often the person who works most closely with patients who are trying to cope with these issues. Interventions include teaching about (1) advantages and disadvantages of new treatments, (2) dangers of poor adherence to therapeutic regimens, (3) how and when to take each drug, (4) drug interactions to avoid, and (5) side effects that must be reported to the health care provider. Table 15-14 provides guidance for patient teaching in these areas.

Guidelines on when and how to initiate ART are based on the degree of immune suppression.[28] Issues to consider when selecting an initial drug regimen include the ability of the patient's HIV to resist specific drugs (assessed by the resistance tests discussed on p. 235), potential medication side effects, existing co-morbidities, and dosing schedules. This is a critical

TABLE 15-15 PATIENT & CAREGIVER TEACHING GUIDE

Improving Adherence to Antiretroviral Therapy

The following are strategies that you can use to improve a patient's adherence to using antiretroviral therapy:

- Determine whether the patient understands the importance of adherence and is ready to start therapy.
- Provide teaching on medication dosing.
- Review potential side effects of drugs.
- Assure the patient that side effects can be treated. If not, medication regimens can be changed.
- Use teaching and memory aids, including pictures, pillboxes, and calendars.
- Engage family and friends in the teaching process. Solicit their support to help the patient take treatment.
- Simplify regimens, dosing, and food requirements as much as possible.
- Use a team of nurses, physicians, pharmacists, case managers, and mental health and peer counselors to support the patient.
- Help the patient integrate the medication regimen into his or her typical life activities and work schedules.

Modified from Centers for Disease Control and Prevention: Guidelines for the use of antiretroviral agents in HIV-1-infected adults and adolescents, 2012. Retrieved from *http://aidsinfo.nih.gov*.

TABLE 15-16 PATIENT & CAREGIVER TEACHING GUIDE

Signs and Symptoms HIV Patients Need to Report

Teach the patient with HIV infection and the caregiver to report the following signs and symptoms.

Report Immediately

- Any change in level of consciousness: lethargic, hard to arouse, unable to be aroused, unresponsive, unconscious
- Headache accompanied by nausea and vomiting, changes in vision, changes in ability to perform coordinated activities, or after any head trauma
- Vision changes: blurry or black areas in vision field, new floaters, double vision
- Persistent shortness of breath related to activity and not relieved by a short rest period
- Nausea and vomiting accompanied by abdominal pain
- Vomiting blood
- Dehydration: unable to eat or drink because of nausea, diarrhea, or mouth lesions; severe diarrhea or vomiting; dizziness when standing
- Yellow discoloration of the skin
- Any bleeding from the rectum that is not related to hemorrhoids or trauma (e.g., from anal sexual intercourse)
- Pain in the flank with fever and inability to urinate for more than 6 hr
- Blood in the urine
- New onset of weakness in any part of the body, new onset of numbness that is not obviously related to pressure, new onset of difficulty speaking
- Chest pain not obviously related to cough
- Seizures
- New rash accompanied by fever
- New oral lesions accompanied by fever
- Severe depression, anxiety, hallucinations, delusions, or thoughts of causing danger to self or others

Report the Following Signs and Symptoms Within 24 Hr

- New or different headache; constant headache not relieved by over-the-counter medication
- Headache accompanied by fever, nasal congestion, or cough
- Burning, itching, or discharge from the eyes
- New or productive cough
- Vomiting 2-3 times a day
- Vomiting accompanied by fever
- New, significant, or watery diarrhea (more than 6 times a day)
- Painful urination, bloody urine, urethral discharge
- Significant new rash (widespread; painful; or following a path down the leg or arm, around the chest, or on the face)
- Difficulty eating or drinking because of mouth lesions
- Vaginal discharge, pain, or itching

decision because the first treatment regimen is generally the patient's best chance for success. However, the most important consideration for initiating therapy is patient readiness.[39]

Adherence to ART is a critical component of successful drug therapy for people with HIV infection. Nurses are uniquely prepared to provide assistance with adherence to the drug regimen[39,41] (Table 15-15). Taking drugs as prescribed (right dose and time) is important for all drug therapy, but with HIV infection, missing even a few doses can lead to drug resistance. Patients can be helped to adhere to difficult treatment regimens with electronic reminders, beepers, timers on pillboxes, and calendars. Group support and individual counseling can also help, but the best approach is to learn about the patient's life and assist with problem solving related to taking medications within the confines of that life.

Delaying Disease Progression. HIV disease progression may be delayed by promoting a healthy immune system, whether the patient chooses to use ART or not. Useful interventions for HIV-infected patients include (1) getting nutritional support to maintain lean body mass and ensure appropriate levels of vitamins and micronutrients; (2) moderating or eliminating alcohol, tobacco, and drug use; (3) keeping up to date with recommended vaccines; (4) getting adequate rest and exercise; (5) reducing stress; (6) avoiding exposure to new infectious agents; (7) accessing mental health counseling; (8) getting involved in support groups and community activities; and (9) developing a consistent relationship with health care providers, including attendance at regular appointments.

Teach patients to recognize symptoms that may indicate disease progression and/or drug side effects so that prompt medical care can be initiated. Table 15-16 provides an overview of symptoms that patients should report.

Acute Exacerbations. Chronic diseases are characterized by acute exacerbations of recurring problems. This is especially true in HIV disease where infections, cancers, debility, and psychosocial or economic issues may interact to overwhelm the patient's ability to cope. Nursing care becomes more complex as the patient's immune system deteriorates and new problems arise to compound existing difficulties.[39] When opportunistic diseases or difficult treatment side effects develop, symptom management, teaching, and emotional support are needed.

Nursing care can help prevent the many opportunistic diseases associated with HIV infection. The best way to prevent opportunistic disease is to ensure that the patient is adhering to an effective ART regimen and, if appropriate, taking prophylactic medications for opportunistic infections. Should an opportunistic disease occur, nursing care can be an essential part of helping the patient adhere to medications and providing supportive care specific to the opportunistic disease. For example, if the patient has *Pneumocystis jiroveci* pneumonia (PCP) (Fig. 15-8), nursing interventions can ensure adequate oxygenation. If the patient has cryptococcal meningitis, an important nursing concern is maintaining a safe environment for a confused patient.

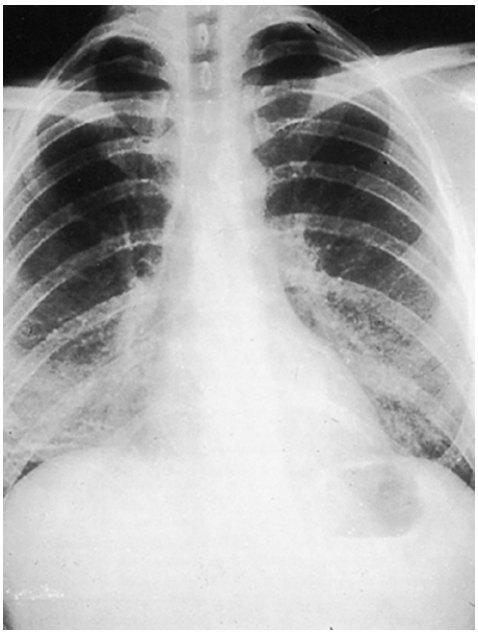

FIG. 15-8 Chest x-ray showing interstitial infiltrates as the result of *Pneumocystis jiroveci* pneumonia.

FIG. 15-9 Lipodystrophy manifestations.

AMBULATORY AND HOME CARE. HIV infection has no cure, continues for life, causes physical disability, and contributes to impaired health. In many cases it can lead to death. HIV infection affects the entire range of a person's life from physical health to social, emotional, economic, and spiritual well-being.

Stigma of HIV. HIV-infected patients share problems experienced by all individuals with chronic diseases, but these problems are exacerbated by negative social constructs surrounding HIV.[42] HIV-infected people may be thought to lack control over urges to have sex or use drugs. Some people then conclude that people with HIV brought the disease on themselves and deserve to be sick. Behaviors associated with HIV infection are viewed by some as immoral (e.g., homosexuality, having many sexual partners) and are sometimes illegal (e.g., using drugs, sex work). The fact that infected individuals can transmit HIV to others creates fear, which leads to stigma and discrimination in all facets of life.

In the United States, HIV-infected people have lost jobs, homes, and insurance, although these forms of discrimination are prohibited by the Americans with Disabilities Act (ADA).[43] HIV-related stigma is a global problem that is often more severe for women. Discrimination can lead to social isolation, dependence, frustration, low self-image, loss of control, and economic pressures.

Disease and Drug Side Effects. Physical problems related to HIV or its treatment can interfere with the patient's ability to maintain a desired lifestyle. HIV-infected patients frequently experience anxiety, fear, depression, diarrhea, peripheral neuropathy, pain, nausea, vomiting, and fatigue. Nursing interventions for these symptoms are similar to what they would be for the patient who does not have HIV infection. For example, nursing management of diarrhea includes helping patients collect specimens, recommending dietary changes, encouraging fluid and electrolyte replacement, instructing the patient about skin care, and managing skin breakdown around the perianal area. Nursing approaches for fatigue in HIV include teaching patients to assess fatigue patterns; determine contributing factors; set activity priorities; conserve energy; schedule rest periods; exercise regularly; and avoid substances such as caffeine, nicotine, alcohol, and other drugs that may disturb sleep.

Some HIV-infected patients, especially those who have been infected and on ART for a long time, develop a set of metabolic disorders that include changes in body shape (fat deposits in the abdomen, upper back, and breasts along with fat loss in the arms, legs, and face) because of lipodystrophy (Fig. 15-9), hyperlipidemia (elevated triglycerides, elevated low-density lipoproteins, and decreased high-density lipoproteins), insulin resistance and hyperglycemia, bone disease (osteoporosis, osteopenia, avascular necrosis), lactic acidosis, renal disease, and cardiovascular disease.[31]

It is still not clear why these disorders develop, but it is probably a combination of factors such as long-term infection with HIV, side effects of ART, genetic predisposition, and chronic stress. Management of metabolic disorders focuses on detecting problems early, dealing with symptoms, and helping the patient cope with emerging problems and changes to treatment regimens. It is important to recognize and treat these problems early, especially because cardiovascular disease and lactic acidosis are potentially fatal complications.

A frequent first intervention is to change ART medications because some drugs are more often associated with these disorders. Lipid abnormalities are generally treated with lipid-lowering drugs (see Table 34-5), dietary changes, and exercise. Insulin resistance is treated with hypoglycemic drugs and weight loss. Bone disease may be improved with exercise, dietary changes, and calcium and vitamin D supplements.

End-of-Life Care. Despite new developments in the treatment of HIV infection, many patients eventually experience disease progression, disability, and death. Sometimes these occur because treatments do not work for the patient. Sometimes the patient's HIV becomes resistant to all available drug therapies. In addition, ART is now allowing people living with HIV to live longer and to develop diseases of aging, such as cardiovascular and endocrine problems that lead to death.

Nursing care during the terminal phase of any disease should focus on keeping the patient comfortable, facilitating emotional and spiritual acceptance of the finite nature of life, helping the patient's significant others deal with grief and loss, and maintaining a safe environment. As a nurse, you are the pivotal care provider during this phase of illness, whether at home, through hospice, or in a health care facility.[39] (End-of-life care is discussed in Chapter 10.)

EVALUATION

The expected outcomes are that the patient at risk for HIV infection will

- Analyze personal risk factors
- Develop and implement a personal plan to decrease risks
- Get tested for HIV

The expected outcomes are that the patient with HIV infection will

- Describe basic aspects of the effects of HIV on the immune system
- Compare and contrast various treatment options for HIV disease
- Work with a team of health care providers to achieve optimal health
- Prevent transmission of HIV to others

GERONTOLOGIC CONSIDERATIONS

HIV INFECTION

The number of older adults who have HIV disease is increasing because (1) HIV treatment has been effective in reducing the number of deaths from HIV-related opportunistic infections and (2) people 60 and older are being infected at increasing rates. The number of people over the age of 60 living with HIV is expected to grow.

Remember that older people living with HIV are susceptible to the same diseases as non-HIV-infected older people. These include heart disease, cancer, diabetes, bone disease, arthritis, hypertension, kidney disease, and cognitive impairment. However, people with HIV infection may experience these diseases at an earlier age (compared with non-HIV-infected people) and may be at higher risk of co-morbidities related to the medications used to treat HIV. For example, some of the HIV medications are associated with increased lipids and altered insulin metabolism. Focusing nursing care on early identification of these complications, and assisting patients in reducing their risk for heart disease, diabetes, or other chronic disease, are critical aspects of caring for the older HIV patient.

Another consideration with the aging HIV population is the impact of polypharmacy. In general, older adults are often prescribed multiple medications to manage various chronic diseases. Some of these medications may interact with or be potentiated by HIV medications. Therefore careful monitoring and assessment of possible drug interactions is important when providing care to this population.

Older adults may be ashamed and hesitate to tell anyone that they have an HIV infection. This may make it difficult for them to get the appropriate health care and support. As a nurse, you need to recognize that HIV is a chronic disease that will affect more and more older adults and be prepared to help the older person who is living with HIV infection.

CASE STUDY

HIV Infection

iStockphoto/Thinkstock

Patient Profile

J.N., a 35-year-old African American woman, was admitted to the hospital in respiratory distress. AIDS and *Pneumocystis jiroveci* pneumonia (PCP) were both diagnosed 2 days ago.

Subjective Data

- Seen by a physician 6 years ago for pain behind the sternum and difficulty swallowing, diagnosed as esophageal candidiasis; positive HIV-antibody test at that time
- Has consistently refused ART because, "We can't afford it"
- Married to Jim, a former IV drug user, for 15 years until his recent death from AIDS-related complications
- Has two children, ages 8 and 10; neither has been tested for HIV infection
- Experiences fatigue and frequent oral and vaginal candidiasis outbreaks
- Expresses concern about the welfare of her children, who are at home with her sister, and says, "Maybe I should take better care of myself for them"

Objective Data

Physical Examination

- 5 ft 6 in tall, 100 lb, temperature 100.4° F (38° C), O_2 saturation 92% on 3 L of O_2 via nasal cannula

Laboratory Studies

- $CD4^+$ T cell count 185 cells/μL
- Viral load 55,328 copies/μL
- Hematocrit 30%

Collaborative Care

- Trimethoprim/sulfamethoxazole
- Combination antiretroviral therapy: tenofovir and emtricitabine (Truvada), darunavir (Prezista), ritonavir (Norvir)

Discussion Questions

1. Why did J.N.'s initial medical problem (esophageal candidiasis) lead to an HIV test?
2. Why was trimethoprim/sulfamethoxazole ordered, and what are its common side effects?
3. What diagnostic criteria for AIDS are present in J.N.?
4. Is there a potential advantage to J.N.'s refusal to take antiretroviral drugs in the past? If so, why or why not?
5. Women often put their children's welfare first. What barriers could this cause for J.N.'s treatment? How can these problems be resolved?
6. ***Priority Decision:*** What priority teaching needs should be covered before J.N. is discharged from the hospital to return home? What referrals need to be made?
7. How can J.N. be helped to adhere to her medication schedule?
8. ***Priority Decision:*** What are the priority nursing interventions? What plans need to be made for continued nursing care after discharge?
9. ***Evidence-Based Practice:*** J.N. asks you if her kids should be tested. She is afraid of what the results may be. How should you respond?

evolve Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Emerging infections can affect health care by *(select all that apply)*
   a. revealing antibiotic resistance.
   b. generating scientific discoveries.
   c. creating a strain on limited resources.
   d. challenging established medical traditions.
   e. limiting travel options for nursing personnel.
2. Which antibiotic-resistant organisms cannot be killed by normal hand soap?
   a. Vancomycin-resistant enterococci
   b. Methicillin-resistant *Staphylococcus aureus*
   c. Penicillin-resistant *Streptococcus pneumoniae*
   d. β-Lactamase–producing *Klebsiella pneumoniae*
3. Transmission of HIV from an infected individual to another most commonly occurs as a result of
   a. unprotected anal or vaginal sexual intercourse.
   b. low levels of virus in the blood and high levels of $CD4^+$ T cells.
   c. transmission from mother to infant during labor and delivery and breastfeeding.
   d. sharing of drug-using equipment, including needles, syringes, pipes, and straws.
4. During HIV infection
   a. the virus replicates mainly in B-cells before spreading to $CD4^+$ T cells.
   b. infection of monocytes may occur, but antibodies quickly destroy these cells.
   c. the immune system is impaired predominantly by the eventual widespread destruction of $CD4^+$ T cells.
   d. a long period of dormancy develops during which HIV cannot be found in the blood and there is little viral replication.
5. Which statements accurately describe HIV infection *(select all that apply)?*
   a. Untreated HIV infection has a predictable pattern of progression.
   b. Late chronic HIV infection is called acquired immunodeficiency syndrome (AIDS).
   c. Untreated HIV infection can remain in the early chronic stage for a decade or more.
   d. Untreated HIV infection usually remains in the early chronic stage for 1 year or less.
   e. Opportunistic diseases occur more often when the $CD4^+$ T cell count is high and the viral load is low.
6. A diagnosis of AIDS is made when an HIV-infected patient has
   a. a $CD4^+$ T cell count below 200/μL.
   b. a high level of HIV in the blood and saliva.
   c. lipodystrophy with metabolic abnormalities.
   d. oral hairy leukoplakia, an infection caused by Epstein-Barr virus.
7. Screening for HIV infection generally involves
   a. laboratory analysis of blood to detect HIV antigen.
   b. electrophoretic analysis for HIV antigen in plasma.
   c. laboratory analysis of blood to detect HIV antibodies.
   d. analysis of lymph tissues for the presence of HIV RNA.
8. Antiretroviral drugs are used to
   a. cure acute HIV infection.
   b. decrease viral RNA levels.
   c. treat opportunistic diseases.
   d. decrease pain and symptoms in terminal disease.
9. Opportunistic diseases in HIV infection
   a. are usually benign.
   b. are generally slow to develop and progress.
   c. occur in the presence of immunosuppression.
   d. are curable with appropriate drug interventions.
10. Which statement about metabolic side effects of ART is true *(select all that apply)?*
    a. These are annoying symptoms that are ultimately harmless.
    b. ART-related body changes include central fat accumulation and peripheral wasting.
    c. Lipid abnormalities include increases in triglycerides and decreases in high-density cholesterol.
    d. Insulin resistance and hyperlipidemia can be treated with drugs to control glucose and cholesterol.
    e. Compared to uninfected people, insulin resistance and hyperlipidemia are more difficult to treat in HIV-infected patients.
11. Which strategy can the nurse teach the patient to eliminate the risk of HIV transmission?
    a. Using sterile equipment to inject drugs
    b. Cleaning equipment used to inject drugs
    c. Taking zidovudine (AZT, ZDV, Retrovir) during pregnancy
    d. Using latex or polyurethane barriers to cover genitalia during sexual contact
12. What is the most appropriate nursing intervention to help an HIV-infected patient adhere to a treatment regimen?
    a. "Set up" a drug pillbox for the patient every week.
    b. Give the patient a video and a brochure to view and read at home.
    c. Tell the patient that the side effects of the drugs are bad but that they go away after a while.
    d. Assess the patient's routines and find adherence cues that fit into the patient's life circumstances.

1. a, b, c, d, 2. a, 3. a, 4. c, 5. a, b, c, 6. a, 7. c, 8. b, 9. c, 10. b, c, d, 11. a, 12. d

LEARNING OUTCOMES

1. Describe the prevalence, incidence, survival, and mortality rates of cancer in the United States.
2. Describe the processes involved in the biology of cancer.
3. Differentiate the three phases of cancer development.
4. Describe the role of the immune system related to cancer.
5. Differentiate among the various classifications of drugs used to treat cancer.
6. Discuss the role of the nurse in the prevention, detection, and diagnosis of cancer.
7. Explain the use of surgery, chemotherapy, radiation therapy, and biologic and targeted therapies in the treatment of cancer.
8. Identify the classifications of chemotherapy agents and methods of administration.
9. Differentiate between teletherapy (external beam radiation) and brachytherapy (internal radiation).
10. Describe the effects of radiation therapy and chemotherapy on normal tissues.
11. Identify the types and effects of biologic and targeted therapy agents.
12. Describe the nursing management of patients receiving chemotherapy, radiation therapy, and biologic and targeted therapy.
13. Describe nutritional therapy for patients with cancer.
14. Identify the various complications associated with advanced cancer.
15. Describe the psychologic support interventions for cancer patients, cancer survivors, and their caregivers.

Cancer is a group of more than 200 diseases characterized by uncontrolled and unregulated growth of cells. Although cancer is often considered a disease of aging, with the majority of cases (77%) diagnosed in those over age 55 years, it occurs in people of all ages. An estimated 1,660,290 people in the United States are diagnosed annually with invasive carcinoma (excluding basal and squamous cell skin cancers).[1]

Overall the incidence of cancer has been declining since the 1990s. The mortality rate for the most common cancers (prostate, breast, lung, and colorectal) is also declining.[2] The incidences of many cancers, such as colorectal, lung, breast, and oropharyngeal cancers, have declined largely as a result of preventive efforts. However, the incidence of other types of cancers, such as leukemia, liver cancer, and skin cancers, has

GENDER DIFFERENCES

Cancer

Men
- More men than women die from cancer-related deaths each year.
- Mortality rate from lung cancer is higher in men than in women.
- Esophageal cancer is more prevalent in men than in women.
- Cancer with the highest incidence among men is prostate cancer.
- Men are more likely to develop liver cancer than women.
- Head and neck cancer occurs more frequently in men than in women.
- Bladder cancer is at least three times more common in men than in women.

Women
- Cancer with the highest death rate among women is lung cancer.
- Nonsmoking women are at a greater risk than nonsmoking men of developing lung cancer.
- Cancer with the highest incidence among women is breast cancer.
- Thyroid cancer is more prevalent in women than in men.
- Women are less likely to have colon cancer screenings than men.

INFORMATICS IN PRACTICE

Managing Cancer Patients' Symptoms

- When patients arrive at some clinics, they are handed a tablet computer. While in the waiting room or chemotherapy infusion unit, with the touch of a finger they select the symptoms they have been experiencing.
- Health care providers can review the information and provide care aimed at managing the patient's specific symptoms.
- After the visit, the notes are stored in the patient's electronic health record. This system can assist with quality of care by determining if standards of care were followed.

been on the rise. Notably, the incidence of melanoma rose faster than that for any other malignancy in the United States.[1]

Cancer incidence overall is higher in men than women. Gender differences in incidence and in death rates for specific cancers are presented in Tables 16-1 and 16-2 and the Gender Differences box. Although mortality rates from all cancers combined are on the decline, cancer is still the second most common cause of death in the United States (heart disease is the most common). However, in people less than 85 years of age, cancer is the leading cause of death. Annually about 580,350 Americans are expected to die as a result of cancer, which is more than 1500 people per day.[1]

Considerable progress has been made in controlling cancer for long periods. More than 13.7 million Americans are alive today who have a history of cancer. The overall 5-year survival rate is now 68% (19% increase over the past 30 years).[1] This statistic represents Americans living with cancer, including those who are disease free, in remission, or undergoing treatment. (Cancer survivors are discussed in this chapter on p. 281.)

Statistics are helpful in describing the scope of cancer as a public health problem, but they cannot describe the combined physiologic, psychologic, and social impact of cancer on individual patients and their caregivers and families. Considerable apprehension is associated with a cancer diagnosis, proportionately more than with other chronic diseases such as heart disease. Despite advances in treatment and care, a great deal of anxiety and fear continue to be associated with a diagnosis of cancer. Education of health care professionals and the public is essential to promote realistic attitudes about cancer and cancer treatment.

You are in a strategic position to lead efforts at changing attitudes about cancer. Furthermore, you can also (1) assist individuals in decreasing their risk of cancer development, (2) help patients comply with cancer management regimens, and (3) support patients and their families as they cope with the effects of cancer and related treatment. You need to be knowledgeable about specific types of cancer, treatment options, management of side effects of therapy, and supportive therapies for cancer.

BIOLOGY OF CANCER

Two major dysfunctions in the process of cancer development are defective cell proliferation (growth) and defective cell differentiation.

Defect in Cell Proliferation

Normally, most tissues contain a population of undifferentiated cells known as stem cells. These stem cells ultimately differentiate and become mature, functioning cells of that tissue and only that tissue.

Cell proliferation originates in the stem cell and begins when the stem cell enters the cell cycle (Fig. 16-1). The time from

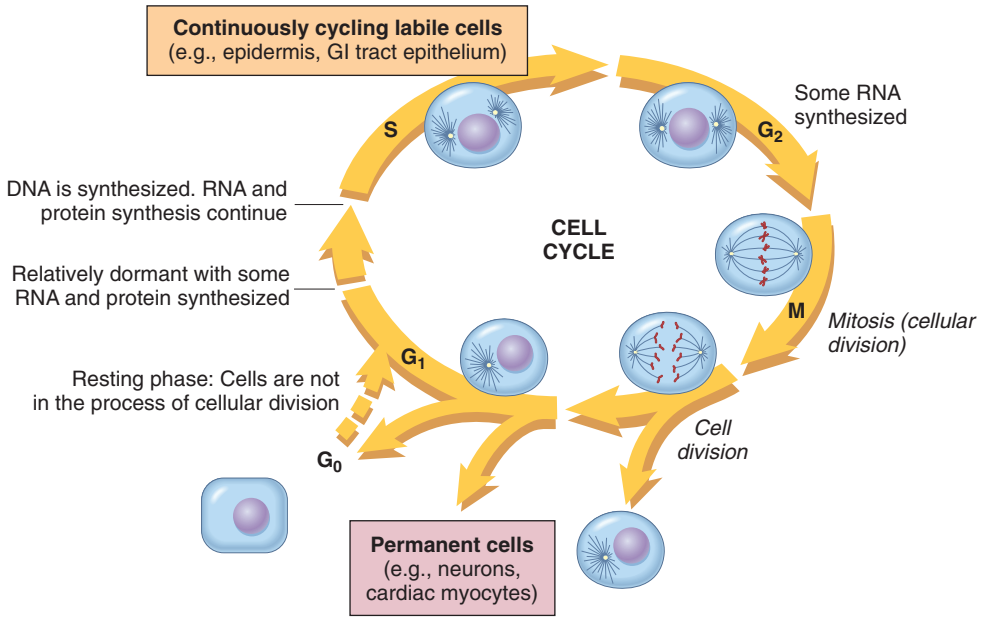

FIG. 16-1 Cell life cycle and metabolic activity. Generation time is the period from *M* phase to *M* phase. Cells not in the cycle but capable of division are in the resting phase *(G_0)*.

when a cell enters the cell cycle to when the cell divides into two identical cells is called the *generation time of the cell*. A mature cell continues to function until it degenerates and dies.

All of the body's cells are controlled by an intracellular mechanism that determines when cell proliferation is necessary. Under normal conditions, a state of dynamic equilibrium is constantly maintained (i.e., cell proliferation equals cell degeneration or death). Normally the process of cell division and proliferation is activated only in the presence of cell degeneration or death. Cell proliferation also occurs if the body has a physiologic need for more cells. For example, a normal increase in white blood cell (WBC) count occurs in the presence of infection.

Another mechanism for proliferation control in normal cells is *contact inhibition*. Normal cells respect the boundaries and territory of the cells surrounding them. They will not invade a territory that is not their own. The neighboring cells are thought to inhibit cell growth through the physical contact of the surrounding cell membranes. Cancer cells grown in tissue culture are characterized by loss of contact inhibition. These cells have no regard for cell boundaries and grow on top of one another and also on top of or between normal cells.

The rate of normal cell proliferation (from the time of cell birth to the time of cell death) differs in each body tissue. In some tissues, such as bone marrow, hair follicles, and epithelial lining of the gastrointestinal (GI) tract, the rate of cell proliferation is rapid. In other tissues, such as myocardium and cartilage, cell proliferation does not occur or is slow.

A common misconception regarding the characteristics of cancer cells is that the rate of proliferation is more rapid than that of normal body cells. Cancer cells usually proliferate at the same rate as the normal cells of the tissue from which they arise. However, cancer cells respond differently than normal cells to the intracellular signals that regulate the state of dynamic equilibrium. The difference is that proliferation of the cancer cells is indiscriminate and continuous. Sometimes they produce more than two cells at the time of mitosis. In this way, there is continuous growth of a tumor mass: $1 \times 2 \times 4 \times 8 \times 16$ and so on. This is termed the *pyramid effect*. The time required for a tumor mass to double in size is known as its *doubling time*.

Defect in Cell Differentiation

Cell differentiation is normally an orderly process that progresses from a state of immaturity to a state of maturity. Because all body cells are derived from the fertilized ova, all cells have the potential to perform all body functions. As cells differentiate, this potential is repressed, and the mature cell is capable of performing only specific functions (see eFig. 16-1 on the website for this chapter). With cell differentiation, there is a stable and orderly phasing out of cell potential. Under normal conditions the differentiated cell is stable and will not *dedifferentiate* (i.e., revert to a previous undifferentiated state).

Genetic Link

Cancer involves the malfunction of genes that control differentiation and proliferation. Two types of normal genes that can be affected by mutation are *protooncogenes* and *tumor suppressor genes*. **Protooncogenes** are normal cell genes that are important regulators of normal cell processes. Protooncogenes promote growth, whereas tumor suppressor genes suppress growth. Mutations that alter the expression of protooncogenes can activate them to function as **oncogenes** (tumor-inducing genes).

The protooncogene has been described as the genetic lock that keeps the cell in its mature functioning state. When this lock is "unlocked," as may occur through exposure to *carcinogens* (agents that cause cancer) or oncogenic viruses, genetic alterations and mutations occur. The abilities and properties that the cell had in fetal development are again expressed. Oncogenes can change a normal cell to a malignant one. This cell regains a fetal appearance and function. For example, some cancer cells produce new proteins, such as those characteristic of the embryonic and fetal periods of life. These proteins, located on the cell membrane, include carcinoembryonic

antigen (CEA) and α-fetoprotein (AFP). They can be detected in human blood by laboratory studies (see Role of the Immune System later in this chapter). Other cancer cells, such as small cell carcinoma of the lung, produce hormones (see Complications Resulting from Cancer later in this chapter) that are ordinarily produced by cells arising from the same embryonic cells as the tumor cells.

Tumor suppressor genes function to regulate cell growth. They prevent cells from going through the cell cycle. Mutations that alter tumor suppressor genes make them inactive, resulting in a loss of their tumor-suppressing action. Examples of tumor suppressor genes are *BRCA1* and *BRCA2*. Alterations in these genes increase a person's risk for breast and ovarian cancer. Another tumor suppressor gene is the *APC* gene. Alterations in this gene increase a person's risk for familial adenomatous polyposis, which is a precursor for colorectal cancer (see Chapter 43). Mutations in the *p53* tumor suppressor gene have been found in many cancers, including bladder, breast, colorectal, esophageal, liver, lung, and ovarian cancers.

Development of Cancer

The following is a theoretical model of the development of cancer. The cause and development of each type of cancer are likely to be multifactorial. A common misbelief is that the development of cancer is a rapid, haphazard event. However, cancer is usually an orderly process that occurs over time and has several stages: initiation, promotion, and progression[2] (Fig. 16-2).

Initiation. Cancer cells arise from normal cells as a result of changes in genes. The first stage, *initiation*, involves a mutation in the cell's genetic structure. A *mutation* is any change in the usual DNA sequence.

Genetic Link

Gene mutations can occur in two different ways: *inherited* from a parent (passed from one generation to the next) or *acquired* during a person's lifetime. (Mutations are discussed in Chapter 13.)

About 5% of all cancers or the predisposition to the cancer is inherited from one's parents. These genetic alterations lead to a high risk of developing a specific type of cancer. However, most cancers do not result from inherited genes but are acquired from damage to genes occurring during one's lifetime.[1] An acquired mutation is passed on to all cells that develop from that single cell. The damaged cell may die or repair itself. However, if cell death or repair does not occur before cell division, the cell will replicate into daughter cells, each with the same genetic alteration.

Carcinogens. Many **carcinogens** (cancer-causing agents capable of producing cell alterations) are detoxified by protective enzymes and are harmlessly excreted. If this protective mechanism fails, carcinogens can enter the cell's nucleus and alter deoxyribonucleic acid (DNA). Carcinogens may be chemical, radiation, or viral.

Chemical Carcinogens. Chemicals were identified as cancer-causing agents in the latter part of the eighteenth century when Percival Pott noted that chimney sweeps had a higher incidence of cancer of the scrotum associated with exposure to soot residue in chimneys. As the years passed, many chemical agents have been identified as carcinogens. People exposed to certain chemicals over time have a greater incidence of certain cancers than others. The long latency period from the time of exposure to the development of cancer makes it difficult to identify cancer-causing chemicals.

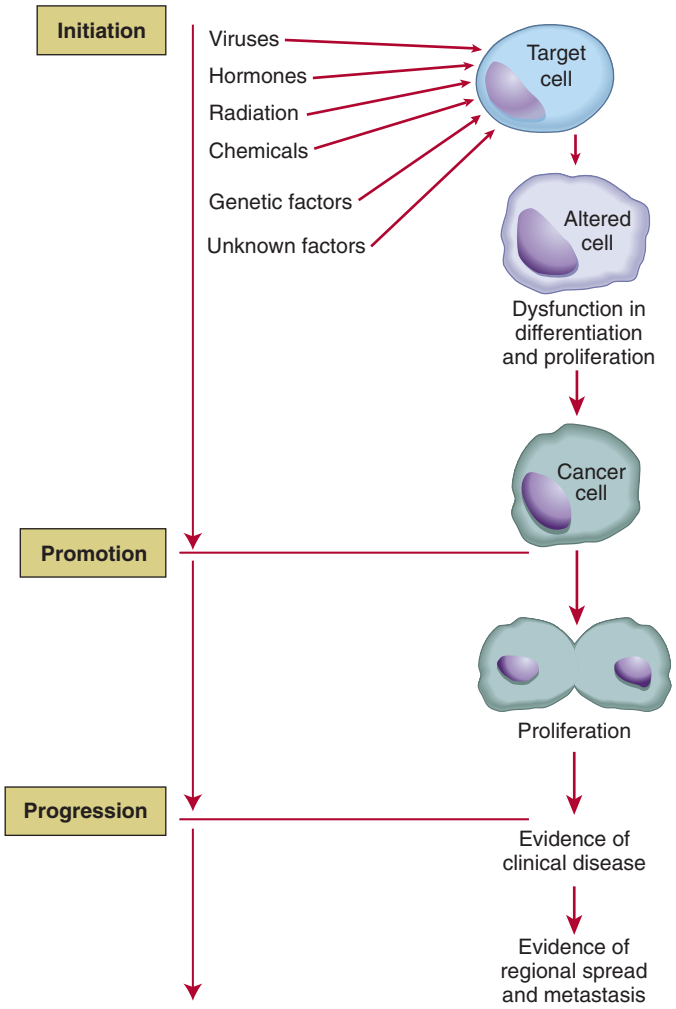

FIG. 16-2 Process of cancer development.

Certain drugs have also been identified as carcinogens. Drugs that are capable of interacting with DNA (e.g., alkylating agents) and immunosuppressive agents have the potential to cause cancer. The use of alkylating agents (e.g., cyclophosphamide [Cytoxan]), either alone or in combination with radiation therapy, has been associated with an increased incidence of acute myelogenous leukemia in people treated for Hodgkin's lymphoma, non-Hodgkin's lymphoma, and multiple myeloma. These *secondary leukemias* are resistant to chemotherapy. Secondary leukemia has also been observed in people who have undergone transplant surgery and taken immunosuppressive drugs.

Radiation. Radiation can cause cancer in almost any body tissue. When cells are exposed to a source of radiation, damage occurs to DNA. Certain malignancies have been correlated with radiation as a carcinogenic agent:

- Leukemia, lymphoma, thyroid cancer, and other cancers increased in incidence in the general population of Hiroshima and Nagasaki after the atomic bomb explosions.
- A higher incidence of bone cancer occurs in people exposed to radiation in certain occupations, such as radiologists, radiation chemists, and uranium miners.

Ultraviolet (UV) radiation has long been associated with melanoma and squamous and basal cell carcinoma of the skin. Skin cancer is the most common type of cancer among whites in the United States. Of great concern is the increase in the incidence of melanoma. Although the cause of melanoma is probably multifactorial, UV radiation secondary to sunlight exposure is linked to the development of melanoma.

Viral Carcinogens. Certain DNA and ribonucleic acid (RNA) viruses, termed *oncogenic,* can transform the cells they infect and induce malignant transformation. Viruses have been identified as causative agents of cancer in animals and humans. Burkitt's lymphoma has consistently shown evidence of Epstein-Barr virus (EBV) in vitro. People with acquired immunodeficiency syndrome (AIDS), which is caused by human immunodeficiency virus (HIV), have a high incidence of Kaposi sarcoma (see Chapter 15). Other viruses that have been linked to the development of cancer include hepatitis B virus, which is associated with hepatocellular carcinoma; and human papillomavirus, which is believed to induce lesions that progress to squamous cell carcinomas, such as cervical, anal, and head and neck cancers.[3]

Promotion. A single alteration of the genetic structure of the cell is not sufficient to result in cancer. However, the odds of cancer development are increased with the presence of promoting agents. *Promotion,* the second stage in the development of cancer, is characterized by the reversible proliferation of the altered cells. An increase in the altered cell population further increases the likelihood of additional mutations.

An important distinction between initiation and promotion is that the activity of promoters is reversible. This is a key concept in cancer prevention. Promoting factors include such agents as dietary fat, obesity, cigarette smoking, and alcohol consumption. Changing a person's lifestyle to modify these risk factors can reduce the chance of cancer development. Approximately half of cancer-related deaths in the United States are related to tobacco use, unhealthy diet, physical inactivity, and obesity.[1]

Several promoting agents have activity against specific types of body tissues. Therefore these agents tend to promote specific kinds of cancer. For example, cigarette smoke is a promoting agent in bronchogenic carcinoma and, in conjunction with alcohol intake, promotes esophageal and bladder cancers.

Some carcinogens, termed *complete carcinogens,* are capable of both initiating and promoting the development of cancer. Cigarette smoke is an example of a complete carcinogen capable of initiating and promoting cancer.

A period of time, ranging from 1 to 40 years, elapses between the initial genetic alteration and the actual clinical evidence of cancer. This period, called the *latent* period, includes both the initiation and the promotion stages in the natural history of cancer. The variation in the length of time that elapses before the cancer becomes clinically evident is associated with the mitotic rate of the tissue of origin and environmental factors. In most cancers the process of developing cancer is years or even decades in length.

For the disease process to become clinically evident, the cells must reach a critical mass. A tumor that is 1.0 cm (0.4 inch) (the size usually detectable by palpation) contains 1 billion cancer cells. A 0.5-cm tumor is the smallest that can be detected by current diagnostic measures, such as magnetic resonance imaging (MRI).

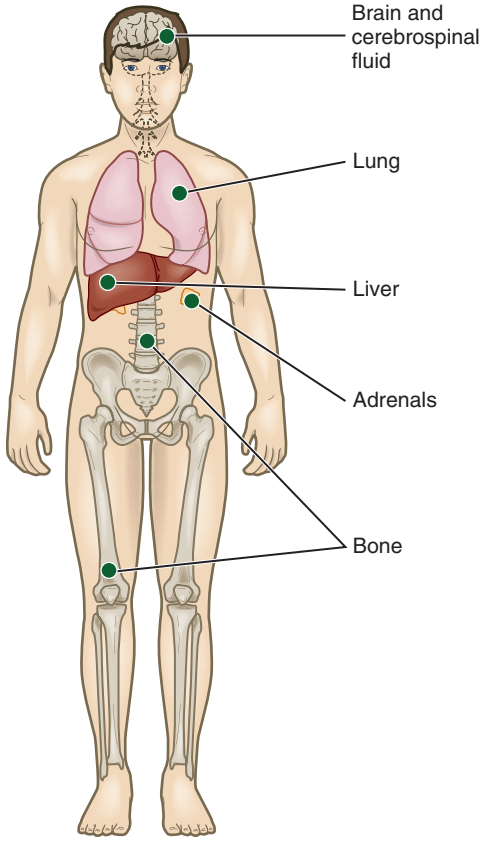

FIG. 16-3 Main sites of metastasis.

Progression. *Progression* is the final stage in the natural history of a cancer. This stage is characterized by increased growth rate of the tumor, increased invasiveness, and **metastasis**—spread of the cancer to a distant site. Certain cancers seem to have an affinity for a particular tissue or organ as a site of metastasis (e.g., colon cancer often spreads to the liver). Other cancers (e.g., melanoma) are unpredictable in their pattern of metastasis. The most frequent sites of metastasis are lungs, liver, bone, brain, and adrenal glands (Fig. 16-3).

Metastasis is a multistep process beginning with the rapid growth of the primary tumor (Fig. 16-4). As the tumor increases in size, development of its own blood supply is critical to its survival and growth. The process of the formation of blood vessels within the tumor itself is termed **tumor angiogenesis** and is facilitated by tumor angiogenesis factors produced by the cancer cells.

Tumor cells are able to detach from the primary tumor, invade the tissue surrounding the tumor, and penetrate the walls of lymph or vascular vessels for metastasis to a distant site. Once free from the primary tumor, metastatic tumor cells frequently travel to distant organ sites via lymphatic and hematogenous routes.

Hematogenous metastasis involves several steps beginning with primary tumor cells penetrating blood vessels. These tumor cells then enter the circulation, travel through the body, and adhere to and penetrate small blood vessels of distant organs. Most tumor cells do not survive this process and are destroyed by mechanical mechanisms (e.g., turbulence of blood flow) and cells of the immune system. However, the formation of a combination of tumor cells, platelets, and fibrin deposits may protect some tumor cells from destruction in blood vessels.

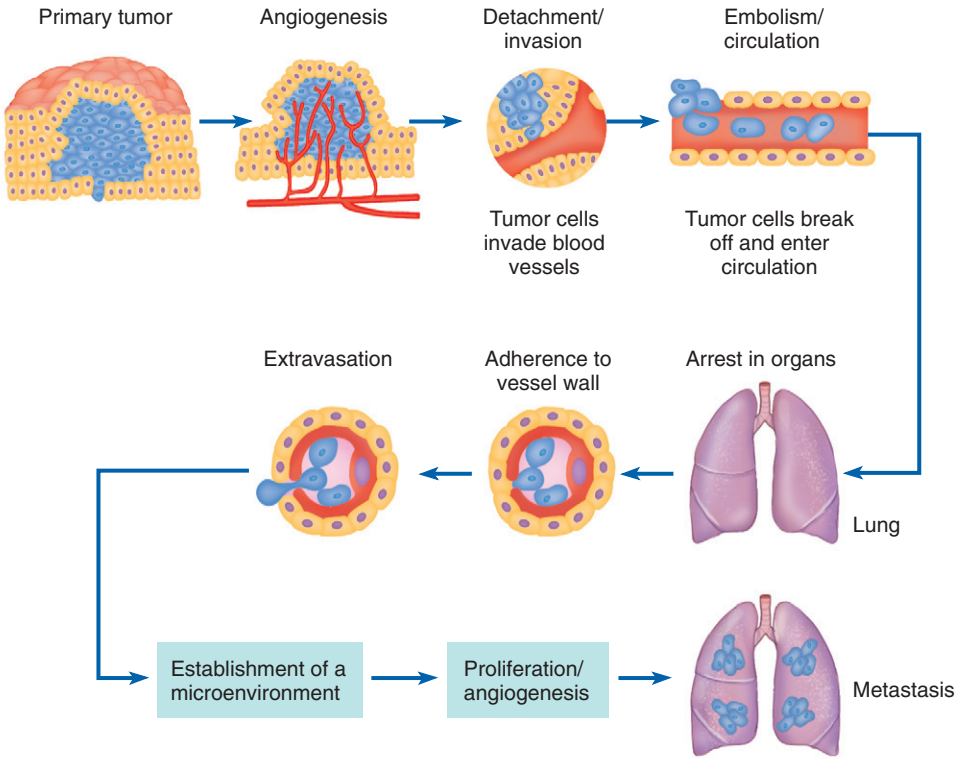

FIG. 16-4 The pathogenesis of cancer metastasis. To produce metastases, tumor cells must detach from the primary tumor and enter the circulation, survive in the circulation to arrest in the capillary bed, adhere to capillary basement membrane, gain entrance into the organ parenchyma, respond to growth factors, proliferate and induce angiogenesis, and evade host defenses.

In the lymphatic system, tumor cells may be "trapped" in the first lymph node confronted or they may bypass regional lymph nodes and travel to more distant lymph nodes, a phenomenon termed *skip metastasis*. This phenomenon is exhibited in malignancies such as esophageal cancers. It also raises questions about the effectiveness of dissection of regional lymph nodes for the prevention of distant metastases.[4]

Tumor cells that do survive the process of metastasis must create an environment in the distant organ site that is conducive to their growth and development. Growth and development are facilitated by the tumor cells' ability to evade cells of the immune system and to produce a vascular supply within the metastatic site similar to that developed in the primary tumor site. Vascularization is critical to the supply of nutrients to the metastatic tumor and to the removal of waste products. Vascularization of the metastatic site is also facilitated by tumor angiogenesis factors produced by the cancer cells.

Role of the Immune System

This section is limited to a discussion of the role of the immune system in the recognition and destruction of tumor cells. (For a detailed discussion of immune system function, see Chapter 14.)

The immune system has the potential to distinguish cells that are normal (self) from abnormal (nonself) cells. For example, cells of transplanted organs can be recognized by the immune system as *nonself* and thus elicit an immune response. This response can ultimately result in the rejection of the organ. Similarly, cancer cells can be perceived as nonself and elicit an immune response resulting in their rejection and destruction. However, unlike transplanted cells, cancer cells arise from normal human cells and, although they are mutated and thus different, the immune response that is mounted against cancer cells may be inadequate to effectively kill them.

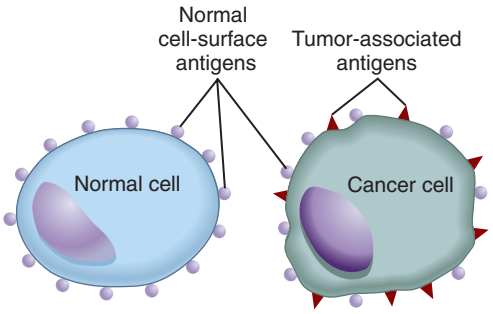

FIG. 16-5 Tumor-associated antigens appear on the cell surface of malignant cells.

Cancer cells may display altered cell-surface antigens as a result of malignant transformation. These antigens are termed **tumor-associated antigens (TAAs)** (Fig. 16-5). It is believed that one of the functions of the immune system is to respond to TAAs. The immune system's response to antigens of the malignant cells is termed **immunologic surveillance.** In this process lymphocytes continuously check cell-surface antigens and detect and destroy cells with abnormal or altered antigenic determinants. Under most circumstances, immune surveillance prevents these transformed cells from developing into clinically detectable tumors.

Immune response to malignant cells involves cytotoxic T cells, natural killer (NK) cells, macrophages, and B cells. *Cytotoxic T cells* play a dominant role in resisting tumor growth.

These cells are capable of killing tumor cells. T cells are also important in the production of cytokines (e.g., interleukin-2 [IL-2] and γ-interferon), which stimulate T cells, NK cells, B cells, and macrophages.

Natural killer (NK) cells are able to directly lyse tumor cells spontaneously without any prior sensitization. These cells are stimulated by γ-interferon and IL-2 (released from T cells), resulting in increased cytotoxic activity.

Monocytes and *macrophages* have several important roles in tumor immunity. Macrophages can be activated by γ-interferon (produced by T cells) to become nonspecifically lytic for tumor cells. Macrophages also secrete cytokines, including interleukin-1 (IL-1), tumor necrosis factor (TNF), and colony-stimulating factors (CSFs). The release of IL-1, coupled with the presentation of the processed antigen, stimulates T lymphocyte activation and production. α-Interferon augments the killing ability of NK cells. TNF causes hemorrhagic necrosis of tumors and exerts cytocidal or cytostatic actions against tumor cells. CSFs regulate the production of various blood cells in the bone marrow and stimulate the function of various WBCs.

B cells can produce specific antibodies that bind to tumor cells. These antibodies are often detectable in the patient's serum and saliva.

Escape Mechanisms From Immunologic Surveillance. The process by which cancer cells evade the immune system is termed *immunologic escape*. Theorized mechanisms by which cancer cells can escape immunologic surveillance include (1) suppression of factors that stimulate T cells to react to cancer cells; (2) weak surface antigens allowing cancer cells to "sneak through" immunologic surveillance; (3) the development of tolerance of the immune system to some tumor antigens; (4) suppression of the immune response by products secreted by cancer cells; (5) the induction of suppressor T cells by the tumor; and (6) blocking antibodies that bind TAAs, thus preventing their recognition by T cells (Fig. 16-6).

Oncofetal Antigens and Tumor Markers. *Oncofetal antigens* are a type of tumor antigen. They are found on both the surfaces and the inside of cancer cells and fetal cells. These antigens are an expression of the shift of cancerous cells to a more immature metabolic pathway, an expression usually associated with embryonic or fetal periods of life. The reappearance of fetal antigens in malignant disease is not well understood, but it is believed to occur as a result of the cell regaining its embryonic capability to differentiate into many different cell types.

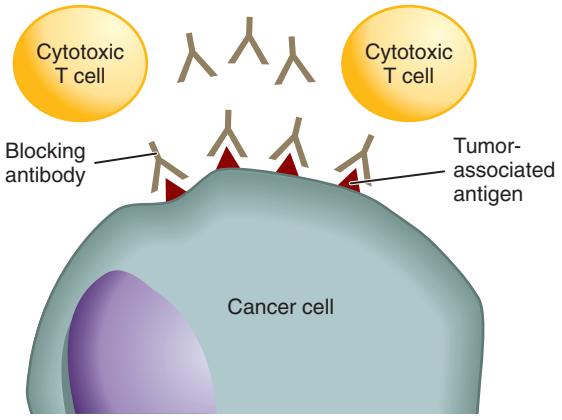

FIG. 16-6 Blocking antibodies prevent T cells from interacting with tumor-associated antigens and from destroying the malignant cell.

Examples of oncofetal antigens are carcinoembryonic antigen (CEA) and α-fetoprotein (AFP). CEA is found on the surfaces of cancer cells derived from the GI tract and from normal cells from the fetal gut, liver, and pancreas. Normally, it disappears during the last 3 months of fetal life. CEA was originally isolated from colorectal cancer cells. However, elevated CEA levels have also been found in nonmalignant conditions (e.g., cirrhosis of the liver, ulcerative colitis, heavy smoking).

These oncofetal antigens can be used as *tumor markers* that may be clinically useful to monitor the effect of therapy and indicate tumor recurrence. However, oncofetal antigens are not 100% specific for tumor recurrence. Tumor markers are affected by various factors that need to be accounted for when reviewing these results. For example, the persistence of elevated preoperative CEA titers after surgery indicates that the tumor is not completely removed. A rise in CEA levels after chemotherapy or radiation therapy may indicate recurrence or spread of the cancer and may be affected by chronic lung or liver disease and smoking.

AFP is produced by malignant liver cells and fetal liver cells. AFP levels have also been found to be elevated in some cases of testicular carcinoma, viral hepatitis, and nonmalignant liver disorders. AFP has diagnostic value in primary cancer of the liver (hepatocellular cancer), but it is also produced when metastatic liver growth occurs. The detection of AFP is of value in tumor detection and determination of tumor progression.

Other examples of oncofetal antigens are CA-125 (found in ovarian carcinoma), CA-19-9 (found in pancreatic and gallbladder cancer), prostate-specific antigen (PSA) (found in prostate cancer), and CA-15-3 and CA-27-29 (found in breast cancer). Molecular markers for specific tumors include kRAS (expression of oncogene in colon cancer), epidermal growth factor receptor (EGFR) often overexpressed in lung cancer, and human epidermal growth factor receptor 2 (HER-2) expression in breast cancer.

BENIGN VERSUS MALIGNANT NEOPLASMS

Tumors can be classified as benign or malignant. In general, *benign neoplasms* are well differentiated, and **malignant neoplasms** range from well differentiated to undifferentiated. The ability of malignant tumor cells to invade and metastasize is the major difference between benign and malignant neoplasms. Other differences are presented in Table 16-3.

CLASSIFICATION OF CANCER

Tumors can be classified according to anatomic site, histology (grading), and extent of disease (staging). Tumor classification

TABLE 16-3 COMPARISON OF BENIGN AND MALIGNANT NEOPLASMS

Characteristic	Benign	Malignant
Encapsulated	Usually	Rarely
Differentiated	Normally	Poorly
Metastasis	Absent	Capable
Recurrence	Rare	Possible
Vascularity	Slight	Moderate to marked
Mode of growth	Expansive	Infiltrative and expansive
Cell characteristics	Fairly normal, similar to parent cells	Cells abnormal, become more unlike parent cells

systems are intended to stratify risk. Classification systems provide a standardized way to (1) communicate the status of the cancer to all members of the health care team, (2) assist in determining the most effective treatment plan, (3) evaluate the treatment plan, (4) predict prognosis, and (5) compare like groups for statistical purposes.

Anatomic Site Classification

In the *anatomic classification* of tumors, the tumor is identified by the tissue of origin, the anatomic site, and the behavior of the tumor (i.e., benign or malignant) (Table 16-4). *Carcinomas* originate from embryonal *ectoderm* (skin and glands) and *endoderm* (mucous membrane linings of the respiratory tract, GI tract, and genitourinary [GU] tract) (see eFig. 16-1 on the website for this chapter). *Sarcomas* originate from embryonal *mesoderm* (connective tissue, muscle, bone, and fat). Lymphomas and leukemias originate from the hematopoietic system.

Histologic Classification

In **histologic grading** of tumors, the appearance of cells and the degree of differentiation are evaluated pathologically. For many tumor types, four grades are used to evaluate abnormal cells based on the degree to which the cells resemble the tissue of origin. Tumors that are poorly differentiated (undifferentiated) have a worse prognosis than those that are closer in appearance to the normal tissue of origin (well differentiated):

Grade I: Cells differ slightly from normal cells (mild dysplasia) and are well differentiated (low grade).
Grade II: Cells are more abnormal (moderate dysplasia) and moderately differentiated (intermediate grade).
Grade III: Cells are very abnormal (severe dysplasia) and poorly differentiated (high grade).
Grade IV: Cells are immature and primitive *(anaplasia)* and undifferentiated; cell of origin is difficult to determine (high grade).
Grade X: Grade cannot be assessed.

TABLE 16-4 ANATOMIC CLASSIFICATION OF TUMORS

Site	Benign	Malignant
Epithelial Tissue Tumors*	**-oma**	**-carcinoma**
Surface epithelium	Papilloma	Carcinoma
Glandular epithelium	Adenoma	Adenocarcinoma
Connective Tissue Tumors†	**-oma**	**-sarcoma**
Fibrous tissue	Fibroma	Fibrosarcoma
Cartilage	Chondroma	Chondrosarcoma
Striated muscle	Rhabdomyoma	Rhabdomyosarcoma
Bone	Osteoma	Osteosarcoma
Nervous Tissue Tumors	**-oma**	**-oma**
Meninges	Meningioma	Meningeal sarcoma
Nerve cells	Ganglioneuroma	Neuroblastoma
Hematopoietic Tissue Tumors		
Lymphoid tissue	—	Hodgkin's lymphoma, non-Hodgkin's lymphoma
Plasma cells	—	Multiple myeloma
Bone marrow	—	Lymphocytic and myelogenous leukemia

*Body surfaces, lining of body cavities, and glandular structures.
†Supporting tissue, fibrotic tissue, and blood vessels.

Extent of Disease Classification

Classifying the extent and spread of disease is termed **staging.** This classification system is based on the anatomic extent of disease rather than on cell appearance. Although there are similarities in the staging of various cancers, there are many differences for specific types of cancer.

Clinical Staging. The clinical staging classification system determines the anatomic extent of the malignant disease process by stages:

Stage 0: cancer in situ
Stage I: tumor limited to the tissue of origin; localized tumor growth
Stage II: limited local spread
Stage III: extensive local and regional spread
Stage IV: metastasis

Clinical staging has been used as a basis for staging a variety of tumor types, including cancer of the cervix (see Table 54-11) and Hodgkin's lymphoma (see Fig. 31-14). Other malignant diseases (e.g., leukemia) do not use this staging approach.

TNM Classification System. The *TNM classification system* (Table 16-5) is used to determine the anatomic extent of the disease involvement according to three parameters: tumor size and invasiveness (T), presence or absence of regional spread to the lymph nodes (N), and metastasis to distant organ sites (M). (Examples of the TNM classification system can be found in Tables 28-17 and 52-6.) TNM staging cannot be applied to all malignancies. For example, the leukemias are not solid tumors and therefore cannot be staged using these guidelines. **Carcinoma in situ (CIS)** refers to a neoplasm whose cells are localized and show no tendency to invade or metastasize to other tissues. CIS has its own designation in the system (T_{is}), since it has all the histologic characteristics of cancer except invasion—a primary feature of the TNM staging system.

Staging of the disease can be performed initially and at several evaluation points. Clinical staging is done at the completion of the diagnostic workup to guide effective treatment selection. Examples of diagnostic studies that may be performed to assess for extent of disease include radiologic studies, such as bone and liver scans; ultrasonography; and computed tomography (CT), MRI, and positron emission tomography (PET) scans.

Surgical staging refers to the extent of the disease as determined by surgical excision, exploration, and/or lymph node

TABLE 16-5 TNM CLASSIFICATION SYSTEM

Primary Tumor (T)

T_0	No evidence of primary tumor
T_{is}	Carcinoma in situ
T_{1-4}	Ascending degrees of increase in tumor size and involvement
T_x	Tumor cannot be measured or found

Regional Lymph Nodes (N)

N_0	No evidence of disease in lymph nodes
N_{1-4}	Ascending degrees of nodal involvement
N_x	Regional lymph nodes unable to be assessed clinically

Distant Metastases (M)

M_0	No evidence of distant metastases
M_{1-4}	Ascending degrees of metastatic involvement, including distant nodes
M_x	Cannot be determined

NOTE: For examples of TNM classification system applied to diseases, see Fig. 31-14 and Table 28-17.

sampling. For example, a laparotomy and a splenectomy may be performed in staging of Hodgkin's lymphoma. During a staging laparotomy, lymph node biopsies may be done, and margins of any masses may be marked with metal clips for use during radiation therapy. However, exploratory surgical staging is being used less frequently as noninvasive diagnostic technology becomes increasingly sophisticated.

After the extent of the disease is determined, the stage classification is not changed. The original description of the extent of the tumor remains part of the record. If additional treatment is needed, or if treatment fails, retreatment staging is done to determine the extent of the disease process before retreatment. "Restaging" classification (rTNM) is differentiated from the stage at diagnosis, since the clinical significance may be quite different.

In addition to tumor classification systems, other rating scales can be used to describe and document the status of patients with cancer at the time of diagnosis, treatment, and retreatment and at each follow-up examination. For example, the Karnofsky Functional Performance Scale and the Katz Index of Independence in Activities of Daily Living describe patient performance in terms of function. (These scales are presented in eTables 16-1 and 16-2 available on the website for this chapter.)

PREVENTION AND EARLY DETECTION OF CANCER

As a nurse, you have an essential role in the prevention and early detection of cancer. Eliminating risk factors reduces the incidence of cancer. For example, rates of smoking-related cancers (e.g., lung and head and neck cancers) have declined following reduction in smoking rates.[1] Early detection and prompt treatment are responsible for increased survival rates in patients with cancer. Colonoscopy is important in reducing colon cancer mortality both by early detection of colon cancers and by prevention (e.g., excision of adenomatous polyps).[5]

Teach patients and the public about cancer prevention and early detection, including the following:

- Reduce or avoid exposure to known or suspected carcinogens and cancer-promoting agents, including cigarette smoke and sun exposure.
- Eat a balanced diet that includes vegetables and fresh fruits (see Fig. 40-1 and Table 40-1), whole grains, and adequate amounts of fiber. Reduce dietary fat and preservatives, including smoked and salt-cured meats containing high nitrite concentrations.
- Limit alcohol intake.
- Participate in regular exercise (i.e., 30 minutes or more of moderate physical activity five times weekly).
- Maintain a healthy weight.
- Obtain adequate, consistent periods of rest (at least 6 to 8 hours per night).
- Eliminate, reduce, or change the perception of stressors and enhance the ability to effectively cope with stressors (see Chapter 7).
- Have a regular physical examination that includes a health history. Be familiar with your own family history and your risk factors for cancer.
- Learn and follow the American Cancer Society's recommended cancer screening guidelines for breast, colon, cervical, and prostate cancer. (See eTable 16-3 on the website for this chapter.)

TABLE 16-6 SEVEN WARNING SIGNS OF CANCER

C	hange in bowel or bladder habits
A	sore that does not heal
U	nusual bleeding or discharge from any body orifice
T	hickening or a lump in the breast or elsewhere
I	ndigestion or difficulty in swallowing
O	bvious change in a wart or mole
N	agging cough or hoarseness

HEALTHY PEOPLE

Prevention and Early Detection of Cancer

- Limit alcohol use.
- Get regular physical activity.
- Maintain a normal body weight.
- Obtain regular colorectal screenings.
- Avoid cigarette smoking and other tobacco use.
- Get regular mammography screening and Pap tests.
- Use sunscreen with a sun protection factor of 15 or higher.
- Practice healthy dietary habits, such as reduced fat consumption and increased fruit and vegetable consumption.

- Learn and practice self-examination (e.g., breast or testicular self-examination).
- Know the seven warning signs of cancer, and inform the health care provider if they are present (Table 16-6). (These actually detect fairly advanced disease.)
- Seek immediate medical care if you notice a change in what is normal for you and if cancer is suspected.

The goals of public education are to (1) motivate people to recognize and modify behaviors that may negatively affect health and (2) encourage awareness of and participation in health-promoting behaviors. When you teach about cancer, try to minimize the fear that surrounds the diagnosis.

Diagnosis of Cancer

When a patient has a possible diagnosis of cancer, it is a stressful time for the patient and the family. Patients may undergo several days to weeks of diagnostic studies. During this time, fear of the unknown may be more stressful than the actual diagnosis of cancer. Patients may also be overwhelmed or confused by the need for multiple diagnostic studies and consultations. Help to coordinate care between multiple specialists and explain the purpose of required tests and any special preparation needed for them.

While patients are waiting for the results of diagnostic studies, be available to actively listen to their concerns. Their anxiety may arise from myths and misconceptions about cancer (e.g., cancer is a "death sentence," cancer treatment is worse than the illness). Correcting those misconceptions can help to minimize their anxiety.

Learn to recognize your own discomfort during difficult conversations. Avoid communication patterns that may hinder exploration of feelings and meaning, such as providing false reassurances (e.g., "It's probably nothing"), redirecting the discussion (e.g., "Let's discuss that later"), generalizing (e.g., "Everyone feels this way"), and using overly technical language as a means of distancing yourself from the patient. These self-protective strategies deny patients the opportunity to share the

meaning of their experience. In addition, they can jeopardize your ability to build a trusting relationship with your patients.

During this time of high anxiety, the patient may need repeated explanations of the diagnostic workup. Include as much information as needed by the patient and the family. Give clear, understandable explanations and reinforce them as needed. Written information is helpful for reinforcement of verbal information.

A diagnostic plan for the person suspected of having cancer includes the health history (including a history of present illness), identification of risk factors, the physical examination, and specific diagnostic studies. For many people, cancer is initially diagnosed after the findings of an abnormal screening test (e.g., mass on mammogram). For others, they are alerted to the presence of cancer by a presenting symptom or cluster of symptoms (e.g., cough and hemoptysis, anorexia and weight loss).

Concentrate on risk factors for malignancy such as family or personal history of cancer, exposure to or use of known carcinogens (e.g., cigarette smoking, occupational pollutants or chemicals, radiation exposure), diseases characterized by chronic inflammation or immunosuppression (e.g., ulcerative colitis), and drug ingestion (e.g., hormone therapy, previous anticancer therapies). Also assess factors that may warrant additional supportive care during therapy, including alcohol or recreational drug use, living situation, social support, and coping strategies for perceived stressors.

Diagnostic studies depend on the suspected primary or metastatic site(s) of the cancer. (Specific procedures as they relate to each body system are discussed in the respective assessment chapters.) Examples of diagnostic studies include the following:

- Cytology studies (e.g., Papanicolaou [Pap] test, bronchial washings)
- Tissue biopsy
- Chest x-ray
- Complete blood count, chemistry profile
- Liver function studies (e.g., aspartate aminotransferase [AST])
- Endoscopic examination: upper GI, sigmoidoscopy, or colonoscopy (including guaiac test for occult blood)
- Radiographic studies (e.g., mammography, ultrasound, CT scan, MRI)
- Radioisotope scans (e.g., bone, lung, liver, brain)
- PET scan (Fig. 16-7)
- Tumor markers (e.g., CEA, AFP, PSA, CA-125)
- Genetic markers (e.g., *BRCA1, BRCA2*)
- Molecular receptor status (e.g., estrogen and progesterone receptors)
- Bone marrow examination (if a hematolymphoid malignancy is suspected or to document metastatic disease)

Biopsy. A *biopsy* is the removal of a tissue sample for pathologic analysis. Various methods are used to obtain a biopsy depending on the location and size of the suspected tumor. *Percutaneous biopsy* is commonly performed for tissue that can be safely reached through the skin. *Endoscopic biopsy* may be used for lung or other intraluminal lesions (esophageal, colon, bladder). When a tumor is not easily accessible, a *surgical procedure* (laparotomy, thoracotomy, craniotomy) is often necessary to obtain a piece of the tumor tissue. Many radiographic techniques may be used in conjunction with the biopsy procedure (e.g., CT, MRI, ultrasound-guided biopsy, stereotactic biopsy, fluoroscopic-assisted biopsy) to improve tissue localization.

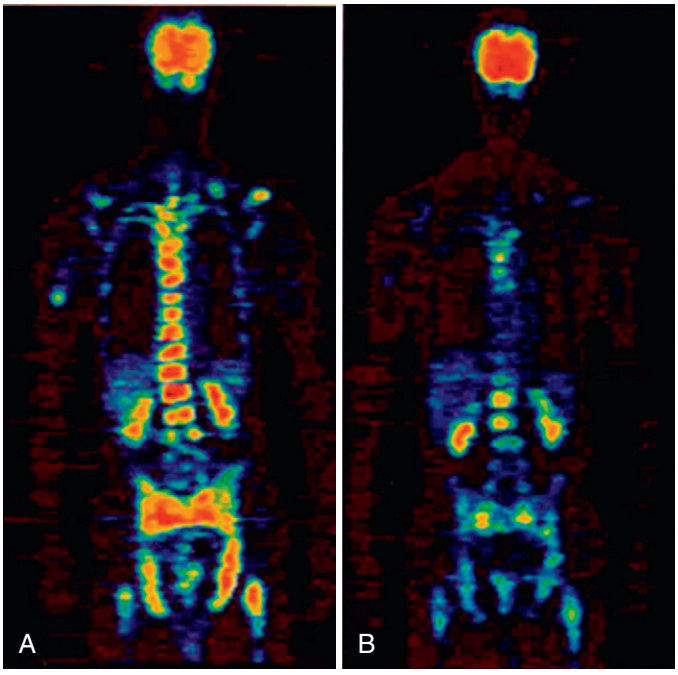

FIG. 16-7 Positron emission tomography (PET) scan before treatment **(A)** indicating metastasis throughout the body. PET scan after treatment **(B)** indicates the effects of therapy. More radioactive material accumulates in areas that have higher levels of activity. This often corresponds to areas of disease and shows up as brighter spots on the PET scan.

Various types and sizes of biopsy needles are available and are selected according to the type of tissue to be sampled. *Fine-needle aspiration* (FNA) may be accomplished with a small-gauge aspiration needle that provides cells from the mass for cytologic examination. *Large-core biopsy* cutting needles deliver an actual piece of tissue (core) that can be analyzed with the advantage of preserving the histologic architecture of the tissue specimen. *Excisional biopsy* involves the surgical removal of the entire lesion, lymph node, nodule, or mass. Therefore it is therapeutic as well as diagnostic. If an excisional biopsy is not feasible, an *incisional biopsy* (partial excision) may be performed with a scalpel or dermal punch.

Pathologic evaluation of a tissue sample is the only definitive means to diagnose a malignancy. The pathologist examines the tissue to determine whether it is benign or malignant, the anatomic tissue from which the tumor arises *(histology),* and the degree of cell differentiation *(histologic grade)*. Other information that can be obtained includes the extent of malignant involvement (size of tumor and depth), evidence of invasiveness (extracapsular, lymphatic), adequacy of surgical excision (positive or negative surgical margin status), nuclear grade (mitotic rate), and special staining techniques that may provide insight into responsiveness of the tumor to treatment or disease behavior (receptor status, tumor markers).

COLLABORATIVE CARE

Treatment Goals

The goals of cancer treatment are cure, control, and palliation (Fig. 16-8). Primary factors that determine what therapy is used are the tumor histology and staging outcomes. Other important factors are the patient's physiologic status (e.g., presence of

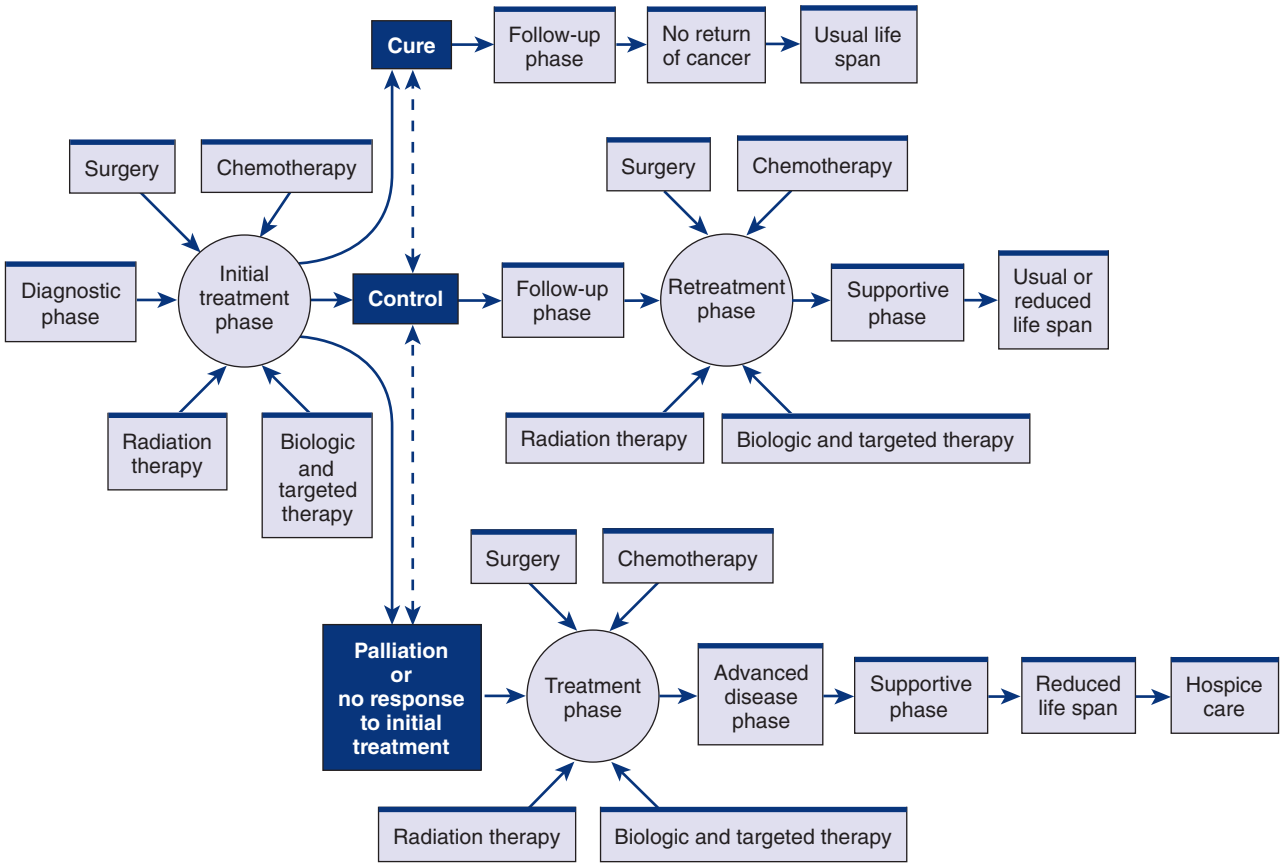

FIG. 16-8 Goals of cancer treatment.

co-morbid illnesses), psychologic status, and personal desires (e.g., active treatment versus palliation of symptoms). These factors influence the modalities chosen for treatment (i.e., surgery, radiation therapy, chemotherapy, biologic and targeted therapy), how therapies are sequenced, and the length of time the treatment is prescribed.

A variety of evidence-based cancer treatment guidelines have been developed to guide the appropriate treatment recommendations for individual patients. Some examples include guidelines of the American Society of Clinical Oncology (ASCO) *(www.asco.org)* and the National Comprehensive Cancer Network (NCCN) *(www.nccn.org)*.

Cure. When caring for the patient and family with cancer, know the treatment goals to appropriately communicate with, teach, and support the patient. When *cure* is the goal, treatment is expected to have the greatest chance of disease eradication. Curative cancer therapy differs according to the particular cancer being treated and may involve local therapies (i.e., surgery or radiation) alone or in combination, with or without periods of adjunctive systemic therapy (i.e., chemotherapy). For example, basal cell carcinoma of the skin is usually cured by surgical removal of the lesion and/or several weeks of radiation therapy. In the treatment plan for acute promyelocytic leukemia (which has curative potential), several chemotherapy drugs are given on a scheduled basis over many months to several years. Testicular cancer can be cured with a combination of surgery, chemotherapy, and radiation.

Although there is no benchmark that ensures "cure" for most malignancies, in general the risk for recurrent disease is highest after treatment completion, and gradually decreases the longer the patient remains disease free following treatment. Cancers with a higher mitotic rate (e.g., testicular cancer) are less likely to recur than cancers with slower mitotic rates (e.g., postmenopausal breast cancer). Therefore the timeframe to consider a person "cured" may differ according to the tumor and its characteristics.

Control. *Control* is the goal of the treatment plan for many cancers that cannot be completely eradicated, but are responsive to anticancer therapies. As with other chronic illnesses (e.g., diabetes mellitus, heart failure), cancer can be maintained for long periods with therapy. Examples include multiple myeloma and chronic lymphocytic leukemia (see Chapter 31). Patients may undergo an initial course of treatment followed by maintenance therapy for as long as the disease is responding. Patients are monitored closely for early signs and symptoms of disease recurrence or progression and the cumulative effects of therapy. Evidence of tumor resistance (such as disease progression) may warrant changing to an alternative therapy.

Palliation. *Palliation* is the treatment goal when relief or control of symptoms and the maintenance of a satisfactory quality of life are the primary objectives. An example of treatment in which palliation is the primary goal includes using radiation therapy or chemotherapy to reduce tumor size and relieve subsequent symptoms such as the pain of bone metastasis.

The goals of cure, control, and palliation are achieved through the use of four treatment modalities for cancer: surgery, radiation therapy, chemotherapy, and biologic and targeted therapy. Each can be used alone or in any combination during initial treatment or as maintenance therapy, as well as in retreat-

ment if the disease does not respond or recurs after remission. For many cancers, two or more of the treatment modalities (known as *multimodality therapy* or *combined modality therapy*) are used to achieve the goal of cure or control for a long time. Multimodality therapy has the benefit of being more effective (because it takes advantage of more than one mechanism of action), but often at the expense of greater toxicity.

SURGICAL THERAPY

Surgery is the oldest form of cancer treatment. The treatment of choice for many years was to remove the cancer and as much of the surrounding normal tissue as possible. What this approach did not fully consider was the ability of malignant cells to travel from the original tumor site to other locations, making surgical cure possible only when the tumor was localized and relatively small. Today surgery is used to meet a variety of goals (Fig. 16-9), and the trend is toward less radical surgeries.

Prevention

Surgical intervention can be used to eliminate or reduce the risk of cancer development. Prophylactic removal of nonvital organs has been successful in reducing the incidence of some malignancies. For example, patients who have adenomatous familial polyposis may benefit from a total colostomy to prevent colorectal cancer (see Chapter 43). Individuals who have genetic mutations of *BRCA1* or *BRCA2* and have a strong family history of early-onset breast cancer may consider having a prophylactic mastectomy (see Chapter 52).

Cure or Control

When the goal is cure or control, the objective is to remove all or as much resectable tumor as possible while sparing normal tissue. Examples of surgical procedures used for cure or control of cancer include radical neck dissection, mastectomy, orchiectomy, thyroidectomy, nephrectomy, hysterectomy, and oophorectomy.

A *debulking* or *cytoreductive procedure* may be used if the tumor cannot be completely removed (e.g., a tumor attached to a vital organ). When this occurs, as much tumor as possible is removed and the patient is given chemotherapy and/or radiation therapy. This type of surgical procedure can make chemotherapy or radiation therapy more effective, since the tumor mass is reduced before treatment is initiated. Other times, a patient may need to receive *neoadjuvant* (treatment before surgery) chemotherapy and/or radiation therapy to reduce tumor burden and improve the surgical outcome.

Supportive and Palliative Care

When cure or control of cancer is no longer possible, the focus shifts to supportive care and palliation of symptoms. Surgical procedures may be used to provide supportive care that maximizes bodily function or facilitates cancer treatment. Examples of supportive surgical procedures include the following:

- Insertion of feeding tube to maintain nutrition during head and neck cancer treatment
- Placement of central venous access devices to deliver chemotherapy agents
- Prophylactic surgical fixation of bones at risk for pathologic fracture

Effects of treatment or symptoms from metastatic cancer may necessitate surgical intervention for palliation. Examples include (1) debulking of tumor to relieve pain or pressure, (2) colostomy for the relief of a bowel obstruction (see Chapter 43), and (3) laminectomy for the relief of a spinal cord compression (see Chapter 61).

CHEMOTHERAPY

Chemotherapy is the use of chemicals as a systemic therapy for cancer. In the 1940s nitrogen mustard, a chemical warfare agent used in World Wars I and II, was used in the treatment of lymphoma and acute leukemia. In the 1970s chemotherapy was established as an effective treatment modality for cancer. Chemotherapy is now a mainstay of cancer treatment for most solid tumors and hematologic malignancies (e.g., leukemias, lymphomas). Chemotherapy can offer cure for some cancers, control other cancers for long periods, and in some instances offer palliative relief of symptoms when cure or control is no longer possible (Fig. 16-10).

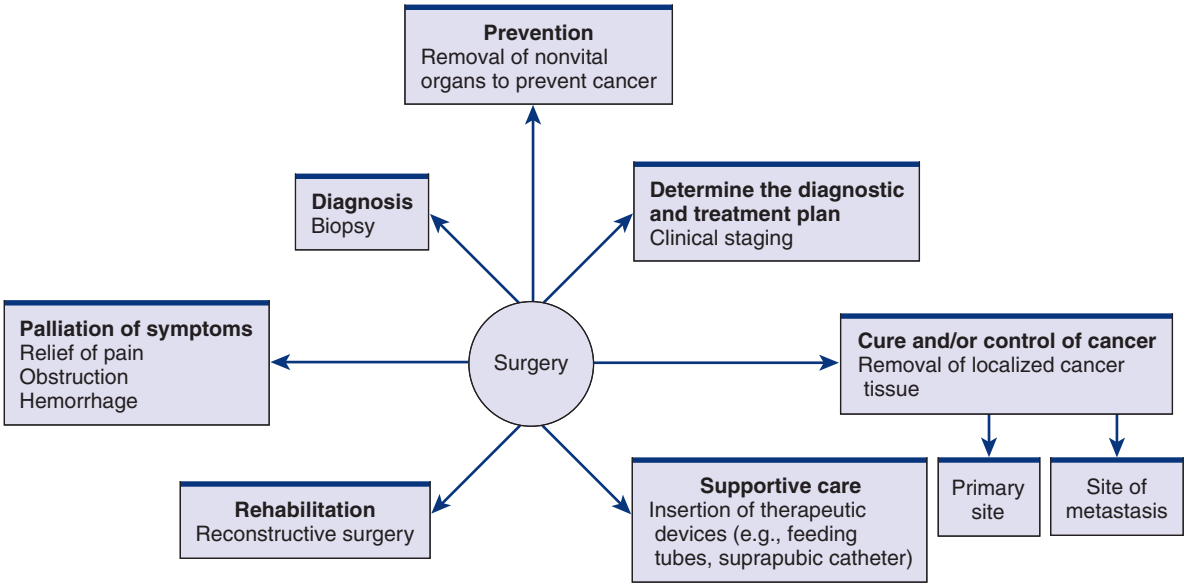

FIG. 16-9 Role of surgery in the treatment of cancer.

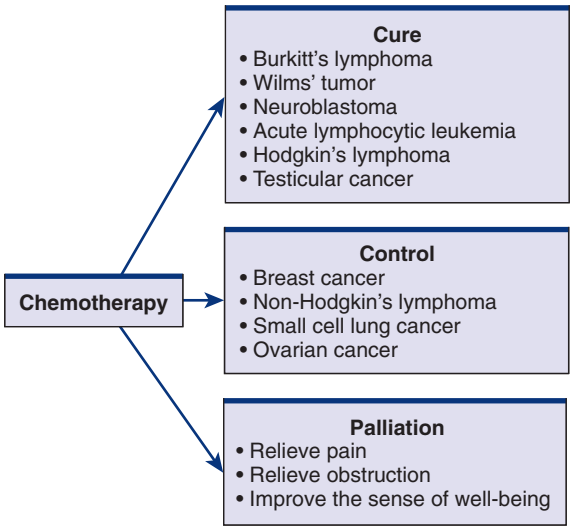

FIG. 16-10 Goals of chemotherapy.

Effect on Cells

The goal of chemotherapy is to eliminate or reduce the number of malignant cells in the primary tumor and metastatic tumor site(s). All cells (cancer cells and normal cells) enter the cell cycle for replication and proliferation (see Fig. 16-1). The effects of the chemotherapy drugs are described in relation to the cell cycle.

The two major categories of chemotherapy drugs are cell cycle phase–nonspecific and cell cycle phase–specific drugs. *Cell cycle phase–nonspecific chemotherapy drugs* have their effect on the cells during all phases of the cell cycle, including the process of cell replication and proliferation and the resting phase (G_0). *Cell cycle phase–specific chemotherapy drugs* exert their most significant effects during specific phases of the cell cycle (i.e., when cells are in the process of cell replication or proliferation during G_1, S, G_2, or M). Cell cycle phase–specific and cell cycle phase–nonspecific agents are often administered in combination to maximize effectiveness by using agents that function by differing mechanisms and throughout the cell cycle.

When cancer first begins to develop, most of the cells are actively dividing. As the tumor increases in size, more cells become inactive and convert to a resting state (G_0). Because most chemotherapy agents are most effective against dividing cells, cells can escape death by staying in the G_0 phase. A major challenge is to overcome the effect of resistant resting and non-cycling cells.

Classification of Chemotherapy Drugs

Chemotherapy drugs are classified in general groups according to their molecular structure and mechanisms of action (Table 16-7). Each drug in a particular classification has many similarities. However, there are major differences in how the drugs work and the unique side effects associated with drugs in each class.

TABLE 16-7 DRUG THERAPY

Chemotherapy Drugs

Mechanisms of Action	Examples
Alkylating Agents ***Cell Cycle Phase–Nonspecific Agents*** Damage DNA by causing breaks in the double-stranded helix. If repair does not occur, cells will die immediately (cytocidal) or when they attempt to divide (cytostatic).	bendamustine (Treanda), busulfan (Myleran), chlorambucil (Leukeran), cyclophosphamide (Cytoxan, Neosar), dacarbazine (DTIC-Dome), ifosfamide (Ifex), mechlorethamine (Mustargen), melphalan (Alkeran), temozolomide (Temodar), thiotepa (Thioplex)
Nitrosoureas ***Cell Cycle Phase–Nonspecific Agents*** Like alkylating agents, break DNA helix, interfering with DNA replication. Cross blood-brain barrier.	carmustine (BiCNU, Gliadel), lomustine (CeeNU), streptozocin (Zanosar)
Platinum Drugs ***Cell Cycle Phase–Nonspecific Agents*** Bind to DNA and RNA, miscoding information and/or inhibiting DNA replication, and cells die.	carboplatin (Paraplatin), cisplatin (Platinol-AQ), oxaliplatin (Eloxatin)
Antimetabolites ***Cell Cycle Phase–Specific Agents*** Mimic naturally occurring substances, thus interfering with enzyme function or DNA synthesis. Primarily act during S phase. Purine and pyrimidine are building blocks of nucleic acids needed for DNA and RNA synthesis.	
• Interfere with purine metabolism.	cladribine (Leustatin), clofarabine (Clolar), fludarabine (Fludara), mercaptopurine (Purinethol), nelarabine (Arranon), pentostatin (Nipent), thioguanine
• Interfere with pyrimidine metabolism.	capecitabine (Xeloda); cytarabine (ara-C [Cytosar-U, DepoCyt]), floxuridine (FUDR), 5-fluorouracil (5-FU [Adrucil]), gemcitabine (Gemzar)
• Interfere with folic acid metabolism.	methotrexate (Rheumatrex, Trexall), pemetrexed (Alimta)
• Interfere with DNA synthesis.	hydroxyurea (Hydrea, Droxia)

NOTE: Many of these drugs are irritants or vesicants that require special attention during administration to avoid extravasation. It is important to know this information about a drug before administering it.

Continued

TABLE 16-7 DRUG THERAPY—cont'd

Chemotherapy Drugs

Mechanisms of Action	Examples
Antitumor Antibiotics	
Cell Cycle Phase–Nonspecific Agents	
Bind directly to DNA, thus inhibiting the synthesis of DNA and interfering with transcription of RNA.	bleomycin (Blenoxane), dactinomycin (Cosmegen), daunorubicin (Cerubidine, DaunoXome), doxorubicin (Adriamycin, Rubex, Doxil), epirubicin (Ellence), idarubicin (Idamycin), mitomycin (Mutamycin), mitoxantrone (Novantrone), plicamycin (Mithracin), valrubicin (Valstar)
Mitotic Inhibitors	
Cell Cycle Phase–Specific Agents	
Taxanes	
Antimicrotubule agents that interfere with mitosis. Act during the late G_2 phase and mitosis to stabilize microtubules, thus inhibiting cell division.	albumin-bound paclitaxel (Abraxane), docetaxel (Taxotere), paclitaxel (Taxol)
Vinca Alkaloids	
Act in M phase to inhibit mitosis.	vinblastine (Velban), vincristine (Oncovin), vinorelbine (Navelbine)
Others	
Microtubular inhibitors.	estramustine (Emcyt), ixabepilone (Ixempra), eribulin (Halaven)
Topoisomerase Inhibitors	
Cell Cycle Phase–Specific Agents	
Inhibit topoisomerases (normal enzymes) that function to make reversible breaks and repairs in DNA that allow for flexibility of DNA in replication.	etoposide (VePesid), irinotecan (Camptosar), teniposide (Vumon), topotecan (Hycamtin)
Corticosteroids	
Cell Cycle Phase–Nonspecific Agents	
Disrupt the cell membrane and inhibit synthesis of protein. Decrease circulating lymphocytes, inhibit mitosis, depress immune system, increase sense of well-being.	cortisone (Cortone), dexamethasone (Decadron), hydrocortisone (Cortef), methylprednisolone (Medrol), prednisone
Hormone Therapy	
Cell Cycle Phase–Nonspecific Agents	
Antiestrogens	
Selectively attach to estrogen receptors, causing down-regulation of them and inhibiting tumor growth. Also known as selective estrogen receptor modulators (SERMs).	fulvestrant (Faslodex), raloxifene (Evista), tamoxifen (Nolvadex), toremifene (Fareston)
Estrogens	
Interfere with hormone receptors and proteins.	estradiol (Estrace), estramustine (Emcyt), estrogen (Menest)
Aromatase Inhibitors	
Inhibit aromatase, an enzyme that converts adrenal androgen to estrogen.	anastrozole (Arimidex), exemestane (Aromasin), letrozole (Femara)
Miscellaneous	
Enzyme derived from the yeast Erwinia used to deplete the supply of asparagine (amino acid) for leukemic cells that are dependent on an exogenous source of this amino acid. Inhibits protein synthesis.	Erwinia asparaginase, L-asparaginase (Elspar)
Causes changes in DNA in leukemia cells and leads to cell death.	arsenic trioxide (Trisenox)
Suppresses mitosis. Appears to alter DNA, RNA, and protein.	procarbazine (Matulane, Natulan)

Preparation of Chemotherapy

It is important to know the specific guidelines for administration of chemotherapy drugs. In addition, it is important to understand that drugs may pose an occupational hazard to health care professionals who do not follow safe handling guidelines. A person preparing, transporting, or administering chemotherapy may absorb the drug through inhalation of particles when reconstituting a powder and through skin contact from exposure to droplets or powder from oral agents. There may also be some risk in handling the body fluids and excretions of people receiving chemotherapy immediately after administration for 48 hours. Only those personnel specifically trained in chemotherapy handling techniques should be involved with the preparation and administration of antineoplastic agents.

Guidelines for the safe handling of chemotherapy agents have been developed by the National Institute for Occupational Safety and Health (available at *www.cdc.gov/niosh/docs/2004-165*) and the Occupational Safety and Health Administration (OSHA) and the Oncology Nursing Society (ONS).[6]

Methods of Administration

Chemotherapy can be administered by multiple routes (Table 16-8). With advances in drug formulation techniques, more oral chemotherapy agents are available.

TABLE 16-8 DRUG THERAPY

Methods of Chemotherapy Administration

Method	Examples
Oral	cyclophosphamide (Cytoxan), capecitabine (Xeloda), temozolomide (Temodar)
Intramuscular	bleomycin (Blenoxane)
Intravenous	doxorubicin (Adriamycin), vincristine (Oncovin), cisplatin (Platinol), 5-fluorouracil (5-FU), paclitaxel (Taxol)
Intracavitary (pleural, peritoneal)	Radioisotopes, alkylating agents, methotrexate
Intrathecal	methotrexate (preservative free), cytarabine
Intraarterial	dacarbazine, 5-FU, methotrexate
Perfusion	Alkylating agents
Continuous infusion	5-FU, methotrexate, cytarabine
Subcutaneous	cytarabine
Topical	5-FU cream

FIG. 16-11 Extravasation injury from infiltration of chemotherapy drug.

The IV route is most common. Major concerns associated with the IV administration of antineoplastic drugs include venous access difficulties, device- or catheter-related infection, and *extravasation* (infiltration of drugs into tissues surrounding the infusion site) causing local tissue damage (Fig. 16-11).

Many chemotherapy drugs are either irritants or vesicants. *Irritants* will damage the intima of the vein, causing phlebitis and sclerosis and limiting future peripheral venous access, but will not cause tissue damage if infiltrated. However, **vesicants,** if inadvertently infiltrated into the skin, may cause severe local tissue breakdown and necrosis. It is extremely important to monitor for and promptly recognize symptoms associated with extravasation of a vesicant and to take immediate action if it occurs. Immediately turn off the infusion and follow protocols for drug-specific extravasation procedures to minimize further tissue damage.

Although pain is the cardinal symptom of extravasation, it can occur without causing pain. Other signs of extravasation are swelling, redness, and vesicles on the skin. After a few days the tissue may begin to ulcerate and necrose. Complications of extravasation include sepsis, scarring, contractures, joint pain, and nerve loss.[6] Vesicants may cause partial- or full-thickness loss of skin. Patients may need surgical intervention varying from debridement to skin grafting.

To minimize the associated physical discomforts, emotional distress, and risks of infection and infiltration, IV chemotherapy can be administered by a *central venous access device* (CVAD). CVADs are placed in large blood vessels and permit frequent, continuous, or intermittent administration of chemotherapy, biologic and targeted therapy, and other products, thus avoiding multiple venipunctures for vascular access. (CVADs are discussed in Chapter 17 on p. 309.)

Regional Chemotherapy Administration

Regional treatment with chemotherapy involves delivery of the drug directly to the tumor site. The advantage of this method is that higher concentrations of the drug can be delivered to the tumor with reduced systemic toxicity. Several regional delivery methods have been developed, including intraarterial, intraperitoneal, intrathecal or intraventricular, and intravesical bladder chemotherapy.

Intraarterial Chemotherapy. Intraarterial chemotherapy delivers the drug to the tumor via the arteries supplying the tumor. This method has been used for the treatment of osteogenic sarcoma; cancers of the head and neck, bladder, brain, and cervix; melanoma; primary liver cancer; and metastatic liver disease. One method of intraarterial drug delivery involves the surgical placement of a catheter that is subsequently connected to an external infusion pump or an implanted infusion pump for infusion of the chemotherapy agent.

Intraperitoneal Chemotherapy. Intraperitoneal chemotherapy involves the delivery of chemotherapy to the peritoneal cavity for treatment of peritoneal metastases from primary colorectal and ovarian cancers and malignant ascites. Temporary Silastic catheters (Tenckhoff, Hickman, and Groshong) are percutaneously or surgically placed into the peritoneal cavity for short-term administration of chemotherapy. Alternatively, an implanted port can be used to administer chemotherapy intraperitoneally. Chemotherapy is generally infused into the peritoneum in 1 to 2 L of fluid and allowed to *dwell* in the peritoneum for 1 to 4 hours. After the *dwell time,* the fluid is drained from the peritoneum.

Intrathecal or Intraventricular Chemotherapy. Cancers that metastasize to the central nervous system (CNS) are difficult to treat because the blood-brain barrier often prevents distribution of chemotherapy to this area. One method used to treat metastasis to the CNS is intrathecal chemotherapy. This method involves a lumbar puncture and injection of chemotherapy into the subarachnoid space. However, this method has resulted in incomplete distribution of the drug in the CNS.

To ensure more uniform distribution of chemotherapy, an Ommaya reservoir is often inserted. An Ommaya reservoir is a Silastic, dome-shaped disk with an extension catheter that is surgically implanted through the cranium into a lateral ventricle. In addition to more consistent drug distribution, the Ommaya reservoir precludes the need for repeated, painful lumbar punctures.

Intravesical Bladder Chemotherapy. *Intravesical bladder chemotherapy* involves instillation of chemotherapy into the bladder. The chemotherapy agent is instilled into the bladder via a urinary catheter and retained for 1 to 3 hours.

Effects of Chemotherapy on Normal Tissues

Chemotherapy agents cannot selectively distinguish between normal cells and cancer cells. Chemotherapy-induced side effects are the result of the destruction of normal cells, especially those that are rapidly proliferating such as those in the bone marrow, the lining of the GI system, and the integumentary system (skin, hair, and nails)[7] (Table 16-9). The general and

TABLE 16-9 CELLS WITH RAPID RATE OF PROLIFERATION

Cells and Generation Time	Effect of Cell Destruction
Bone marrow stem cell, 6-24 hr	Myelosuppression (infection, bleeding, anemia)
Neutrophils, 12 hr	Leukopenia, infection
Epithelial cells lining the gastrointestinal tract, 12-24 hr	Anorexia, mucositis (including stomatitis, esophagitis), nausea and vomiting, diarrhea
Cells of the hair follicle, 24 hr	Alopecia
Ova or testes, 24-36 hr	Reproductive dysfunction

drug-specific adverse effects of these drugs are classified as acute, delayed, or chronic.

Acute toxicity occurs during and immediately after drug administration and includes anaphylactic and hypersensitivity reactions, extravasation or a flare reaction, anticipatory nausea and vomiting, and cardiac dysrhythmias.

Delayed effects are numerous and include delayed nausea and vomiting, mucositis, alopecia, skin rashes, bone marrow suppression, altered bowel function (diarrhea or constipation), and a variety of cumulative neurotoxicities.

Chronic toxicities involve damage to organs such as the heart, liver, kidneys, and lungs. Chronic toxicities can be either long-term effects that develop during or immediately after treatment and persist, or late effects that are absent during treatment and manifest later.

Some side effects fall into more than one category. For example, nausea and vomiting can be both acute and delayed.

Treatment Plan

Although single-drug chemotherapy is sometimes prescribed, combining agents in multidrug regimens has proven to be more effective in managing most cancers. The regimens with multiple agents involve drugs with different mechanisms of action and varying toxicity profiles. However, when chemotherapy agents are used in combination, patients can experience an increase in toxicities.

Drug regimens are selected based on evidence supporting their use in specific cancers. Sometimes they are customized to meet the needs of an individual patient. Chemotherapy is most effective when the tumor burden is low, therapy is not interrupted, and the patient receives the intended dose. The dose of each drug is based on the individual's body weight and height using the body surface area calculation.

Mutation of cancer cells within the tumor can result in cells that are resistant to chemotherapy. With the use of multiple drugs that work at different places in the cell cycle, cancer cells can be more effectively killed. Thus mutation and resistance of cancer cells can be prevented.

RADIATION THERAPY

Along with surgery, radiation therapy is one of the oldest methods of cancer treatment. It was first used by Emil Grubbe (a medical student) to treat an ulcerating breast cancer in 1896 (although the patient responded locally, she died later of metastatic disease). The observation that radiation exposure caused tissue damage led scientists to explore the use of radiation to treat tumors. The hypothesized association was that if radiation exposure resulted in the destruction of highly mitotic skin cells, it could be used in a controlled way to prevent the continued growth of cancer cells.

It was not until the 1960s that sophisticated equipment and treatment planning facilitated the delivery of adequate radiation doses to tumors and tolerable doses to normal tissues. Currently, about half of all cancer patients receive radiation therapy at some point in their treatment.[8]

Effects of Radiation

Radiation is energy that is emitted from a source and travels through space or some material. Delivery of high-energy beams, when absorbed into tissue, produces ionization of atomic particles. The energy in ionizing radiation acts to break the chemical bonds in DNA. The DNA is damaged, resulting in cell death.

Different types of ionizing radiation are used to treat cancer, including *electromagnetic radiation* (i.e., x-rays, gamma rays) and *particulate radiation* (alpha particles, electrons, neutrons, protons). High-energy x-rays (photons) are generated by an electric machine, such as a linear accelerator (sometimes referred to as a *linac*).

Technologic advances have expanded and refined the sources and methods of delivering radiation therapy, thus offering more accurate and less invasive radiation treatment options. Most radiation centers in the United States currently use megavoltage linear accelerator technology. Larger radiation facilities may offer a combination of machines that permit expanded options for patients at one treatment site.

Principles of Radiobiology

As the radiation beam passes through the treatment field, energy is deposited. *Low-energy beams* (such as electrons) expend energy quickly on impact with matter. Therefore they penetrate only a short distance. (They are clinically useful in treating superficial skin lesions.) *High-energy beams* (such as photons) have greater depth of penetration, not attaining full intensity until they reach a certain depth. Therefore they are suitable for delivering optimal doses to internal targets while sparing the skin. The principles of radiation therapy are guided by cell response to radiation, known as the four *R*s of radiobiology (see eTable 16-4 on the website for this chapter).

Technically, all cancer cells could be killed with radiation given in high enough doses. However, to avoid serious toxicity and long-term complications of treatment, radiation to surrounding healthy tissue must be limited to the *maximal tolerated dose* for that specific tissue. Advances in planning and in delivery technology (such as *intensity-modulated radiation therapy [IMRT]* and *image-guided radiation therapy [IGRT]*) have greatly improved the ability to deliver maximal doses to the target volume while sparing critical structures (e.g., spinal cord, carotid arteries, optic chiasm) as much as possible.

Historically, the radiation dose was expressed in units called *rads* (radiation absorbed doses). Current nomenclature is *gray* (Gy) or centigray (cGy). A *centigray* is equivalent to 1 rad, and 100 centigray equals 1 gray.

Once the total dose to be delivered is determined, that dose is divided into daily *fractions*. Doses between 180 and 200 cGy/day are considered *standard fractionation,* typically delivered once a day Monday through Friday for a period of 2 to 8 weeks (depending on the desired total dose). Other treatment schedules may be prescribed based on principles of radiobiologic effect. High daily doses of radiation may be given with fewer

TABLE 16-10 TUMOR RADIOSENSITIVITY*

High Radiosensitivity
- Ovarian dysgerminoma
- Testicular seminoma
- Hodgkin's lymphoma
- Non-Hodgkin's lymphoma
- Wilms' tumor
- Neuroblastoma

Moderate Radiosensitivity
- Oropharyngeal carcinoma
- Esophageal carcinoma
- Breast adenocarcinoma
- Uterine and cervical carcinoma
- Prostate carcinoma
- Bladder carcinoma

Mild Radiosensitivity
- Soft tissue sarcomas (e.g., chondrosarcoma)
- Gastric adenocarcinoma
- Renal adenocarcinoma
- Colon adenocarcinoma

Poor Radiosensitivity
- Osteosarcoma
- Malignant melanoma
- Malignant glioma
- Testicular nonseminoma

*Radiosensitivity is the relative susceptibility of cells and tissues to the effects of radiation.

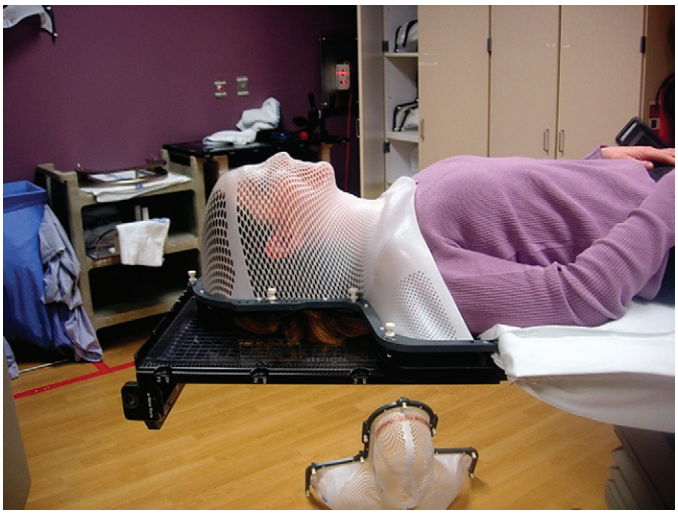

FIG. 16-12 Immobilization device. A head holder and an immobilization mask may be used to ensure accurate positioning for daily treatment of head and neck cancer.

fractions *(hypofractionated),* lower doses may be given more than once daily *(hyperfractionated),* or standard doses may be delivered twice daily over a shortened treatment time *(accelerated fractionation).*

The amount of time required for the manifestations of radiation damage is determined by the mitotic rate of the tissue, with rapidly proliferating tissues being more sensitive. Rapidly dividing cells in the GI tract, oral mucosa, and bone marrow die quickly and exhibit early acute responses to radiation. Tissues with slowly proliferating cells, such as cartilage, bone, and kidneys, manifest later responses to radiation. This differential rate of cell death explains the timing of clinical manifestations related to radiation therapy.

Certain cancers are more susceptible to the effects of radiation than others (Table 16-10). In responsive tumors (such as lymphomas), even a large tumor burden is affected by radiation therapy. In less responsive tumors, a large tumor burden may result in a slower and perhaps incomplete response. Localized prostate cancer responds very slowly to radiation (several months after treatment is completed).

Simulation and Treatment Planning

Simulation is a process by which the radiation treatment fields are defined, filmed, and marked out on the skin. The radiation oncologist specifies the dose and volume of area to be treated. Treatment volumes include the (1) *gross target v*olume (GTV), which is the gross extent of the tumor identified by examination or imaging; (2) the *clinical target* volume (CTV), which is the GTV plus additional margin to encompass any potential microscopic or subclinical disease; and (3) the *planning target volume* (PTV), which is the GTV/CTV plus additional margin to allow for organ motion or variance in daily set-up position.[9]

During the simulation, goals of the radiation plan are met by determining the orientation and size of radiation beams, defining the location of field-shaping blocks, and outlining the field on the patient's skin. The patient is positioned on a simulator, which is a diagnostic x-ray machine that re-creates the actions of the linear accelerator. Immobilization devices (e.g., casts, bite blocks, thermoplastic face masks) are typically used to help the patient maintain a stable position (Fig. 16-12).

The target is defined using a variety of possible imaging techniques (e.g., x-rays; CT, MRI, PET scans), physical examination, and surgical reports. Under fluoroscopy or with CT-based treatment planning, the critical normal structures that will be included in the treatment field (or portal) are identified so they can be protected. A film is taken to verify the field, and marks are placed on the skin to delineate the "treatment port." Small tattoos may be placed to ensure the patient position is precisely reproduced on a daily basis.

Treatment

Radiation is used to treat a carefully defined area of the body. Since radiation only has an effect on tissues within the treatment field, it is not appropriate as the primary treatment for systemic disease. However, radiation may be used by itself, in combination with chemotherapy or surgery to treat primary tumors, or for palliation of metastatic lesions (see eTable 16-5 on the website for this chapter).

External Radiation. Radiation can be delivered externally (known as *teletherapy* or *external beam radiation therapy*) or internally *(brachytherapy).* **Teletherapy** *(external beam radiation)* is the most common form of radiation treatment delivery. With this technique, the patient is exposed to radiation from a megavoltage treatment machine. A linear accelerator, which generates ionizing radiation from electricity and can have multiple energies, is the most commonly used machine for delivering external beam radiation (Fig. 16-13). *Gamma knife technology* (used to deliver highly accurate stereotactic treatment to a localized treatment volume) uses a cobalt source. A cyclotron produces particulate energy, such as neutrons or protons. Proton therapy requires significant energy to generate, and only a small number of facilities in the United States are equipped to provide this treatment.

A linear accelerator may be used to deliver different types of treatment techniques (or plans). A *two-dimensional* plan is the simplest type of therapy, designed using x-rays, bony landmarks, and a simple beam arrangement. *Three-dimensional-conformal therapy* plans treatment based on three-dimensional anatomy using CT and/or other imaging, with the goal of improved dose distribution around the target volume. *Intensity-modulated radiation therapy* (IMRT) involves an inverse planning process, in which multiple beams of varying intensity deliver tailored treatment doses to a precise treatment field. It

FIG. 16-13 Linear accelerator. Varian Clinac EX linear accelerator with multiple photon and electron energies available for use according to the treatment plan. Patient is positioned on radiation treatment table for treatment of head and neck cancer.

is more labor intensive to plan but has the advantage of tailoring beam intensity to optimize dose delivery to the target volume while minimizing dose to critical structures. It is particularly well suited to treating irregularly shaped fields and fields adjacent to sensitive structures (e.g., head and neck cancers).

Volumetric-modulated arc therapy (VMAT) and *tomotherapy* build on IMRT to further improve accuracy of dose delivery. With VMAT, the dose is delivered in one to three continuous arcs around the patient. An advantage of VMAT over standard IMRT is dramatically reduced treatment time, often delivering treatments in 3 to 5 minutes that previously would have taken 20 to 30 minutes.

Tomotherapy is a similar concept, but is done with a specialized linear accelerator built into a round gantry (similar to a CT scanner). The gantry rotates spirally around the patient advancing through the "doughnut," and treatment is thus delivered in "slice by slice" fashion. Dosimetry with tomotherapy appears to be comparable or superior to standard IMRT or VMAT, but is not as time efficient as VMAT.

Image-guided radiation therapy (IGRT) (sometimes referred to as *four-dimensional-conformal* therapy) further optimizes the delivery of conformal or IMRT treatment plans by addressing the element of physiologic movement over time. IGRT incorporates methods to control for physiologic movement during therapy, or anatomic changes (such as tumor shrinkage or weight loss), on a daily basis or over time during the treatment course. Imaging (usually CT, fluoroscopy, or ultrasound) may be performed in conjunction with the radiation treatment to detect any variations in tumor position or organ movement. Images are taken daily before treatment and compared with the original treatment plan so that "shifts" can be made if necessary to accommodate for any variations in target localization. Such tracking and visualization of tumor position during treatment may further improve the accuracy of dose delivery to the intended target volume. Although it is unclear how much these technologies will affect survival, IMRT treatment planning can reduce treatment toxicity, especially for prostate and head and neck cancers.

Internal Radiation. Radiation can also be delivered as **brachytherapy,** which means "close" or internal radiation treatment. It consists of the implantation or insertion of radioactive materials directly into the tumor (interstitial) or in close proximity to the tumor (intracavitary or intraluminal). This allows for direct delivery of radiation to the target with minimal exposure to surrounding healthy tissues. (In external radiation, the beam has to pass through external tissues to reach the internal target.) Brachytherapy is commonly used in combination with external radiation as a supplemental "boost" treatment, but may also be used as primary or adjuvant therapy.

Sources of radiation for brachytherapy include temporary sealed sources such as iridium-192 and cesium-137 and permanent sealed sources such as iodine-125, gold-198, and palladium-103. These are supplied in the form of seeds or ribbons. With a temporary implant, the source may be placed into a special catheter or metal tube that has been inserted into the tumor area. It is left in place until the prescribed dose of radiation has been reached in the calculated number of hours.

Brachytherapy may be delivered as high-dose-rate (HDR) treatment (i.e., several doses administered at varying intervals over a few minutes each time) or low-dose-rate (LDR) treatment (i.e., continuous treatment over several hours or days). A remote "afterloading" technique (i.e., the source is inserted after the applicator is in place) is designed to enhance physician and patient safety and is used for HDR brachytherapy with iridium-192. These methods are commonly used for head and neck, lung, breast, and gynecologic malignancies.

Permanent implants, such as for prostate brachytherapy, involve the insertion of radioactive seeds directly into the tumor tissue, where they remain permanently. As interstitial seeds used for treatment emit low energies with limited tissue penetration, patients are not considered radioactive. However, some initial radiation precautions may be recommended because of a small risk of seed dislodgement. Over time, the isotopes that are used decay and are no longer radioactive. The timeframe for side effects induced by treatment can be predicted based on the rate of decay for the specific isotope used.

Radiopharmaceutical therapy employs unsealed liquid radioactive sources that are administered orally as a drink, such as iodine-131 for thyroid cancer, or IV as with yttrium-90 given for refractory lymphomas or samarium-153 used to treat bone metastases.

Caring for the person undergoing brachytherapy or receiving radiopharmaceuticals requires that you be aware that the patient is emitting radioactivity. Patients with temporary implants are radioactive only while the source is in place. In patients with permanent implants, because the sources have fairly short half-lives and are weak emitters, the radioactive exposure to the outside and to others is low. These patients may be discharged with minimal precautions.

The principles of *ALARA (as low as reasonably achievable)* and *time, distance,* and *shielding* are vital to health care professional safety when caring for the person with a source of internal radiation. Organize care to limit the time spent in direct contact with the patient. To minimize anxiety and confusion, tell the patient the reason for time and distance limitations before the procedure.

The radiation safety officer will indicate how much time at a specific distance can be spent with the patient. This is determined by the dose delivered by the implant. Because the source is nonpenetrating, small differences in distance are critical.

Only care that must be delivered near the source, such as checking placement of the implant, is performed in close proximity. Use shielding, if available, and do not deliver care without wearing a film badge indicating cumulative radiation exposure. Do not share the film badge, do not wear it anywhere but at work, and return it according to the agency's protocol.

NURSING MANAGEMENT CHEMOTHERAPY AND RADIATION THERAPY

You have an important role in helping patients deal with the side effects of chemotherapy and radiation therapy. Before initiating teaching, assess the patient's ability to process information. Customize teaching to meet the patient's and the family's learning needs.

Common side effects of chemotherapy and radiation are presented in Table 16-11. Bone marrow suppression, fatigue, GI disturbances, integumentary and mucosal reactions, and pulmonary and reproductive effects are discussed in this section.

NURSING IMPLEMENTATION

BONE MARROW SUPPRESSION. Myelosuppression is one of the most common effects of chemotherapy and, to a lesser extent, it can also occur with radiation. Treatment-induced reductions in blood cell production can result in life-threatening and distressing effects, including infection, hemorrhage, and overwhelming fatigue. The major difference in manifestations between radiation therapy and chemotherapy is that with radiation (a local therapy), only bone marrow within the treatment field is affected, whereas chemotherapy (a systemic therapy) affects bone marrow function throughout the body. Therefore effects are more profound with chemotherapy and when the two therapies are combined.

In general, the onset of bone marrow suppression is related to the life span of the type of blood cell. WBCs (especially neutrophils) are affected most acutely (within 1 to 2 weeks), platelets in 2 to 3 weeks, and red blood cells (RBCs), with a longer life span of 120 days, at a later time. The severity of myelosuppression depends on the chemotherapy drugs used, dosages of drugs, and the specific radiation treatment field. Radiation to large marrow-containing regions of the body produces the most clinically significant myelosuppression. In the adult, most of the active marrow is in the pelvis or thoracic and lumbar vertebrae.

Monitor the complete blood count, particularly the neutrophil, platelet, and RBC counts, in patients receiving chemotherapy or radiation. Typically patients experience the lowest blood cell counts (called the **nadir**) between 7 and 10 days after initiation of therapy. However, the exact onset depends on the particular drug regimen.

Neutropenia is more common in patients receiving chemotherapy than radiation therapy. Neutropenia is a serious risk factor for life-threatening infection and sepsis. Significant neutropenia will prompt treatment delay or modification (i.e., lower dosages). Take every possible measure to prevent infections in these patients. Hand hygiene is the mainstay of patient protection. Patients and their contacts (including hospital staff) should follow hand-washing guidelines. Other precautions to minimize risks from neutropenia are presented in eTable 16-6, available on the website for this chapter.

Monitor temperature routinely. Any sign of infection should be treated promptly, since fever in the setting of neutropenia is a medical emergency. WBC growth factors (i.e., filgrastim [Neupogen], pegfilgrastim [Neulasta]) are routinely used to reduce the duration of chemotherapy-induced neutropenia. They are also used as a prophylactic measure to prevent neutropenia when highly myelosuppressive chemotherapy drugs are used.[10] (Neutropenia is discussed in Chapter 31; see also the patient teaching guide in Table 31-24 and eNursing Care Plan 31-2 on the website for that chapter.)

Thrombocytopenia can result in spontaneous bleeding or major hemorrhage. Avoid invasive procedures and advise patients to avoid activities that place them at risk for injury or bleeding (including excessive straining). Risk of serious bleeding is generally not apparent until the platelet count falls below 50,000/μL. Platelet transfusions may be necessary and are usually administered when platelet counts fall below 20,000/μL. (Thrombocytopenia is discussed in Chapter 31; see also the patient teaching guide in Table 31-16 and eNursing Care Plan 31-1 on the website for that chapter.)

Anemia is common in patients undergoing either radiation therapy or chemotherapy. It generally has a later onset (about 3 to 4 months after treatment initiation). For patients with low hemoglobin levels, RBC growth factors (i.e., darbepoetin [Aranesp], epoetin [Procrit]) may be given according to clinical guidelines for use. In extreme circumstances (i.e., symptomatic anemia), RBC transfusions may also be indicated. However, in general, RBC transfusions should be avoided. (Hematopoietic growth factors are discussed later in this chapter and presented in Table 16-14 on p. 274.)

FATIGUE. *Fatigue* is the persistent subjective sense of tiredness associated with cancer and its treatment that interferes with usual day-to-day functioning. Fatigue is a nearly universal symptom affecting most patients with cancer. It is commonly reported by patients as the most distressful of treatment-related side effects. Furthermore, it may persist long after treatment has ended.

Anemia is one cause of fatigue. Other causes may be related to (1) the accumulation of toxic substances that are left in the body after cells are killed by cancer treatment, (2) the need for extra energy to repair and heal body tissue damaged by treatment, and (3) lack of sleep caused by some chemotherapy drugs. Assess for reversible causes of fatigue, such as anemia, hypothyroidism, depression, anxiety, insomnia, dehydration, or infection.[11]

Help patients recognize that fatigue is a common side effect of therapy, and encourage energy conservation strategies. Help individuals identify days or times during the day when they typically feel better, and encourage them to remain more active during that time period. Resting before activity and having others assist with work or home management may be necessary. Ignoring the fatigue or overstressing the body when fatigue is tolerable may lead to an increase in symptoms. However, maintaining exercise and activity within tolerable limits is often helpful in managing fatigue. Walking programs are a way for most patients to keep active without overtaxing themselves. Remaining active helps to improve mood and avoid the debilitating cycle of fatigue-depression-fatigue that can occur in patients with cancer.

Published guidelines for the evaluation and management of cancer-related fatigue have been developed by the NCCN[11] and are available at *www.nccn.org*.

GASTROINTESTINAL EFFECTS. The cells of the mucosal lining of the GI tract are highly proliferative, with epithelial cells being replaced every 2 to 6 days. The intestinal mucosa is one of the

TABLE 16-11 NURSING MANAGEMENT OF PROBLEMS CAUSED BY CHEMOTHERAPY AND RADIATION THERAPY

Etiology	Nursing Management
Gastrointestinal System	
Stomatitis, Mucositis, Esophagitis	
• Epithelial cells are destroyed by chemotherapy or radiation treatment when located in field (e.g., head and neck, stomach, esophagus). • Inflammation and ulceration occur due to rapid cell destruction.	• Assess oral mucosa daily and teach patient to do this. • Encourage nutritional supplements (e.g., Ensure, Carnation Instant Breakfast) if intake decreasing. • Be aware that eating, swallowing, and talking may be difficult (may require analgesics). • Instruct in diet modification as necessary (avoidance of irritating spicy or acidic foods; selection of moist, bland, and softer foods). • Encourage patient to keep oral cavity clean and moist by performing frequent oral rinses with saline or salt and soda solution. • Encourage patient to use artificial saliva to manage dryness (radiation). • Discourage use of irritants such as tobacco and alcohol. • Apply topical anesthetics (e.g., viscous lidocaine, oxethazaine).
Nausea and Vomiting	
• Release of intracell breakdown products stimulates vomiting center in brain. • Drugs also stimulate vomiting center in brain (see Fig. 42-1). • GI lining destroyed with radiation and chemotherapy.	• Encourage patient to eat and drink when not nauseated. • Administer antiemetics prophylactically before chemotherapy and also on as-needed basis. • Instruct patient to take antiemetics on a scheduled basis for 2-3 days after highly emetogenic chemotherapy. • Use diversional activities (if appropriate).
Anorexia	
• Release of TNF and IL-1 from macrophages has appetite-suppressant effect. • Therapy-induced GI effects (mucositis, nausea and vomiting, bowel disturbances) and anxiety reduce appetite.	• Monitor weight. • Encourage patient to eat small, frequent meals of high-protein, high-calorie foods. • Gently encourage patient to eat, but avoid nagging. • Recommend keeping a food diary to track daily calories and fluids. • Serve food in pleasant environment.
Diarrhea	
• From denuding of epithelial lining of intestines. • Side effect of chemotherapy. • Follows radiation to abdomen, pelvis, lumbosacral areas.	• Give antidiarrheal drugs as needed. • Encourage low-fiber, low-residue diet. • Encourage fluid intake of at least 3 L/day.
Constipation	
• Decreased intestinal motility is related to autonomic nervous system dysfunction. • Caused by neurotoxic effects of plant alkaloids (vincristine, vinblastine).	• Instruct patient to take stool softeners as needed, eat high-fiber foods, and increase fluid intake. • Instruct patient to increase activity (e.g., walking) if tolerated.
Hepatotoxicity	
• Toxic effects from chemotherapy drugs (usually transient and resolve when drug is stopped).	• Monitor liver function tests.
Hematologic System	
Anemia	
• Bone marrow depressed secondary to therapy. • Malignant infiltration of bone marrow by cancer.	• Monitor hemoglobin and hematocrit levels. • Administer iron supplements and erythropoietin. • Encourage intake of foods that promote RBC production (see Table 31-5).
Leukopenia	
• Depression of bone marrow secondary to chemotherapy or radiation therapy. • Infection most frequent cause of morbidity and death in cancer patients. • Respiratory and genitourinary system usual sites of infection.	• Monitor WBC count, especially neutrophils. • Tell patient to report temperature elevation and any other manifestations of infection. • Teach patient to avoid large crowds and people with infections. • Administer WBC growth factors (see Table 16-14). • For patient teaching, see Table 31-24.
Thrombocytopenia	
• Bone marrow depressed secondary to chemotherapy. • Malignant infiltration of bone marrow crowds out normal marrow. • Spontaneous bleeding can occur with platelet counts ≤20,000/μL.	• Observe for signs of bleeding (e.g., petechiae, ecchymosis). • Monitor platelet counts. • For patient teaching, see Table 31-16.
Integumentary System	
Alopecia	
• Destruction of hair follicles by chemotherapy or radiation to scalp. • Hair loss usually is temporary with chemotherapy, but usually permanent in response to radiation.	• Suggest ways to cope with hair loss (e.g., hair pieces, scarves, wigs). • Cut long hair before therapy. • Avoid excessive shampooing, brushing, and combing of hair. • Avoid use of electric hair dryers, curlers, and curling rods. • Discuss impact of hair loss on self-image.

TABLE 16-11 NURSING MANAGEMENT OF PROBLEMS CAUSED BY CHEMOTHERAPY AND RADIATION THERAPY—cont'd

Etiology	Nursing Management
Radiation Skin Changes (dry to moist desquamation)	
• Radiation damages skin.	• See Table 16-12 for patient management details.
Chemotherapy-Induced Skin Changes	
• Hyperpigmentation • Telangiectasia • Photosensitivity • Acneiform eruptions • Acral erythema	• Alert patient to potential skin changes. • Encourage patient to avoid sun exposure. • Implement symptomatic management as needed depending on specific skin effect (e.g., application of lotions, benzoyl peroxide for acne, corticosteroid creams).
Genitourinary Tract	
Hemorrhagic Cystitis	
• Cells lining bladder are destroyed by chemotherapy (e.g., cyclophosphamide, ifosfamide). • Side effect of radiation when located in treatment field.	• Encourage increased fluid intake 24-72 hr after treatment as tolerated. • Monitor manifestations such as urgency, frequency, and hematuria. • Administer cytoprotectant agent (mesna [Mesnex]) and hydration. • Administer supportive care agents to manage symptoms (e.g., flavoxate [Urispas]).
Reproductive Dysfunction	
• Cells of testes or ova are damaged by therapy.	• Discuss possibility with patients before treatment initiation. • Offer opportunity for sperm and ova banking before treatment for patients of childbearing age.
Nephrotoxicity	
• Direct renal cell damage from exposure to nephrotoxic agents (cisplatin and high-dose methotrexate). • Precipitation of metabolites of cell breakdown (tumor lysis syndrome [TLS]).	• Monitor BUN and serum creatinine levels. • Avoid potentiating drugs. • Alkalinize the urine with sodium bicarbonate and administer allopurinol (Zyloprim) or rasburicase for TLS prevention.
Nervous System	
Increased Intracranial Pressure	
• May result from radiation edema in central nervous system.	• Monitor neurologic status. • May be controlled with corticosteroids.
Peripheral Neuropathy	
• Paresthesias, areflexia, skeletal muscle weakness, and smooth muscle dysfunction can occur as a side effect of plant alkaloids, taxanes, and cisplatin.	• Monitor for these manifestations in patients on these drugs. • Consider temporary chemotherapy dose interruption or reduction until symptoms improve. • Antiseizure drugs (e.g., gabapentin [Neurontin]) may be considered.
Cognitive Changes ("chemo brain")	
• Occur during and after treatment (especially with chemotherapy). • Difficulties in concentration, memory lapses, trouble remembering details, taking longer to finish tasks. • May happen quickly and last a short time. Sometimes people have mild long-term effects.	• Teach patients to do the following: • Use detailed daily planner. • Get enough sleep and rest. • Exercise brain (learn something new, do word puzzles). • Focus on one thing (no multitasking).
Respiratory System	
Pneumonitis	
• Radiation pneumonitis develops 2-3 mo after start of treatment. • After 6-12 mo, fibrosis occurs and is evident on x-ray. • Side effect of some chemotherapy drugs.	• Monitor for dry, hacking cough; fever; and exertional dyspnea.
Cardiovascular System	
Pericarditis and Myocarditis	
• Inflammation secondary to radiation injury. • Complication when chest wall is irradiated. May occur up to 1 yr after treatment. • Side effect of some chemotherapy drugs.	• Monitor for clinical manifestations of these disorders (e.g., dyspnea).
Cardiotoxicity	
• Some chemotherapy drugs (e.g., anthracyclines, taxanes) can cause ECG changes and rapidly progressive heart failure.	• Monitor heart with ECG and cardiac ejection fractions. • Drug therapy may need to be modified for symptoms or deteriorating cardiac function studies.
Biochemical	
Hyperuricemia	
• Increased uric acid levels due to chemotherapy-induced cell destruction. • Can cause secondary gout and obstructive uropathy.	• Monitor uric acid levels. • Allopurinol may be given as a prophylactic measure. • Encourage increased fluid intake.
Psychoemotional	
Fatigue	
• Anabolic processes result in accumulation of metabolites from cell breakdown.	• Assess for reversible causes of fatigue, and address them as indicated. • Reassure patient that fatigue is a common side effect of therapy. • Encourage patient to rest when fatigued, to maintain usual lifestyle patterns as much as possible, and to pace activities in accordance with energy level. • Encourage moderate exercise as tolerated.

BUN, Blood urea nitrogen; *IL-1,* interleukin-1; *TNF,* tumor necrosis factor.

most sensitive tissues to radiation and chemotherapy. The etiology of GI reactions is related to a variety of mechanisms, including (1) the release of serotonin from the GI tract, which then stimulates the chemoreceptor trigger zone (CTZ) and the vomiting center in the brain; and (2) cell death and resulting damage to GI mucosa. Additionally, radiation to treatment fields that contain GI structures (i.e., abdominopelvic, lumbosacral, and lower thoracic areas) and selected chemotherapy agents produce direct injury to GI epithelial cells. These injuries result in a variety of GI effects, including nausea and vomiting, diarrhea, mucositis, and anorexia. These problems can significantly affect the patient's hydration and nutritional status and sense of well-being.

Nausea and Vomiting. Nausea and vomiting are common sequelae of chemotherapy and, in some instances, radiation therapy. Vomiting may occur within 1 hour of chemotherapy administration or a few hours after radiation therapy to the chest or abdomen and may persist for 24 hours or more. Several antiemetic drugs are available (see Table 42-1). Metoclopramide (Reglan), prochlorperazine (Compazine), serotonin ($5\text{-}HT_3$) receptor antagonists (ondansetron [Zofran], granisetron [Kytril], dolasetron [Anzemet], and palonosetron [Aloxi]), and dexamethasone (Decadron) have been used to decrease nausea and vomiting caused by chemotherapy. Aprepitant (Emend), a neurokinin-1 receptor antagonist, is effective in preventing nausea and vomiting on the day of chemotherapy, as well as for delayed symptoms.[12,13]

Patients may also develop *anticipatory nausea and vomiting* if they experience poorly controlled nausea and vomiting after chemotherapy administration. In this phenomenon, encountering the cues even without receiving treatment may precipitate nausea and vomiting. Aggressive emesis control, including the prophylactic administration of antiemetic and antianxiety medication 1 hour before treatment, is recommended. The patient may find that eating a light meal of nonirritating food before treatment is also helpful.

Delayed nausea and vomiting can develop 24 hours to a week after treatment. Assess patients experiencing nausea and vomiting for signs and symptoms of dehydration and metabolic alkalosis. Nausea and vomiting can be successfully managed with antiemetic regimens, dietary modification, and other nondrug interventions (e.g., relaxation breathing).

Diarrhea. Diarrhea is a reaction of the bowel mucosa to radiation and to certain chemotherapy drugs. It is characterized by an increase in frequency and liquidity of stool. The small bowel is extremely sensitive and does not tolerate significant radiation doses. With pelvic radiation, patients may be treated with a full bladder to move the small bowel out of the treatment field. Both radiation- and chemotherapy-induced diarrhea are best managed with diet modification, antidiarrheals, antimotility agents, and antispasmodics (see Table 43-2).

Recommend a diet low in fiber and residue before treatment with chemotherapy known to cause diarrhea. This includes limiting foods that are high in roughage (e.g., fresh fruits, vegetables, seeds, nuts) (see Table 43-6). To prevent diarrhea, other foods to avoid include fried, fatty, or highly seasoned foods and other foods that are gas producing. Bowel mucosal injury from radiation may also result in temporary lactose intolerance. Therefore avoiding milk products is helpful for some patients during and immediately after treatment.

Depending on the severity of the diarrhea, hydration and electrolyte supplementation are also recommended. Lukewarm sitz baths may alleviate discomfort and cleanse the rectal area if significant rectal irritation has developed. The rectal area must be kept clean and dry to maintain skin integrity. You should visually inspect the perianal area for evidence of skin breakdown. Systemic analgesia may be warranted for the painful skin irritations that may develop. Note the number, volume, consistency, and character of stools per day. Teach patients to maintain a diary or log to record episodes and aggravating and alleviating factors.[14]

Mucositis. Mucositis (irritation, inflammation, and/or ulceration of the mucosa) is a common complication in almost all patients receiving radiation to the head and neck and in many patients receiving certain antineoplastic agents, especially 5-fluorouracil (5-FU). Similar to the bowel mucosa, the mucosal linings of the oral cavity, oropharynx, and esophagus are extremely sensitive to the effects of radiation and chemotherapy.

Certain factors can compound the problem. For example, patients undergoing head and neck radiation may face the additional challenge of radiation-induced parotid gland dysfunction. This may result in decreased salivary flow, causing acute or chronic *xerostomia* (dry mouth). Dryness or thick saliva compromises the protective salivary functions of assisting with cleansing teeth, moistening food, and swallowing. Meticulous oral care during and for a long time after treatment reduces the risk of cavities related to the radiation, which may develop as a result of diminished saliva. Advise patients to continue regular dental follow-up every 6 months and to use fluoride supplements as recommended by their dentist. Saliva substitutes may be offered to patients with xerostomia, although many patients find that drinking small amounts of water frequently has a similar effect.

Amifostine (a cytoprotectant) may be used during radiation treatment if a significant radiation dose to the parotid glands is expected. It may help to reduce radiation-related mucositis.

Dysgeusia (taste loss) may develop during therapy, and by the end of treatment patients often report that all food has lost its flavor. Ultimately, nutritional status may be compromised. *Dysphagia* (difficulty swallowing), which characterizes pharyngeal and/or esophageal involvement, further impedes eating. Patients may report feeling that they have a "lump" as they swallow and that "foods get stuck." *Odynophagia* (painful swallowing) caused by oropharyngeal or esophageal irritation and ulceration may require the use of analgesics before meals.

Oral assessment and meticulous intervention to keep the oral cavity moist, clean, and free of debris are essential to prevent infection and to facilitate nutritional intake. Implementing standard oral care protocols that address prevention and management of mucositis facilitates routine assessment, patient and family education, and intervention.

Routinely assess the oral cavity, mucous membranes, characteristics of saliva, and ability to swallow. Having a dentist perform all necessary dental work before the initiation of treatment is also recommended. Teach patients to self-examine the oral cavity and also how to perform oral care (proper tooth brushing with a soft-bristle toothbrush, flossing, and use of fluoride trays to prevent caries). Oral care should be performed at least before and after each meal, at bedtime, and as needed through the day. A saline solution of 1 tsp of salt in 1 L of water is an effective cleansing agent. One tsp of sodium bicarbonate may be added to the oral care solution to decrease odor, alleviate pain, and dissolve mucin.

Mucositis or pain in the throat can be alleviated by systemic and/or topical analgesics and antibiotics if infection is present. Monitor and get prompt treatment for oral candidiasis (which often occurs with mucositis). Frequent cleansing with saline and water and topical application of anesthetic gels directly to the lesions are standard care.

Palifermin (Kepivance), a synthetic version of keratinocyte growth factor, is available to prevent or shorten the duration of mucositis. It is given IV and stimulates growth of cells on the surface layer of the mouth. This leads to faster replacement of these cells when killed by cancer treatment. It may also speed up the healing process of mouth ulcers. Palifermin is currently recommended for mucositis prevention in patients with hematologic malignancies undergoing treatment. The safety and efficacy of palifermin have not been established in patients with nonhematologic malignancies.

Anorexia. Anorexia (loss of appetite) is a common occurrence in patients with cancer. It is a side effect of the cancer itself as well as of cancer treatment. Anorexia may be related to an inflamed mouth or esophagus, which creates difficulty chewing or swallowing, or to emotions such as anxiety or depression.

Patients experiencing nausea and vomiting, bowel disturbances, mucositis, and taste alterations typically have little desire to eat. Although it is highly individual, anorexia seems to peak at about 4 weeks of treatment and to resolve more quickly than fatigue when treatment ends.

Monitor the patient with anorexia during and after treatment to ensure that weight loss does not become excessive. Also observe for dehydration. Small, frequent meals of high-protein, high-calorie foods are better tolerated than large meals. Nutritional supplements can be helpful as well. Enteral or parenteral nutrition may be indicated if the patient is severely malnourished, if symptoms are expected to interfere with nutrition for a time, or if the bowel is being rested. Monitor for and manage other symptoms that may interfere with appetite (e.g., nausea, vomiting, pain, depression).[15]

SKIN REACTIONS

Radiation Skin Changes. With radiation, skin effects are local, occurring only in the treatment field. Radiation-induced skin changes can be acute or chronic depending on the area irradiated, dosage, and technique. The skin-sparing ability of modern radiation equipment limits the severity of these reactions. Erythema may develop 1 to 24 hours after a single treatment, but generally occurs progressively as the treatment dose accumulates. Erythema is an acute response followed by dry desquamation (Fig. 16-14). If the rate of cell sloughing is faster than the ability of the new epidermal cells to replace dead cells, a wet desquamation occurs with exposure of the dermis and weeping of serous fluid (Fig. 16-15). Skin reactions are particularly evident in areas of skinfolds or where skin is subjected to pressure, such as behind the ear; in gluteal folds; or on the perineum, breast, collar line, and bony prominences.

Although skin care protocols vary among institutions, basic skin care principles apply. The goal is to prevent infection and facilitate wound healing. Protect radiated skin from temperature extremes. Do not use heating pads, ice packs, and hot water bottles in the treatment field. Avoid constricting garments, rubbing, harsh chemicals, and deodorants, since they may traumatize the skin. Dry reactions are uncomfortable and result in pruritus. Lubricate dry skin with a nonirritating lotion emollient that contains no metal, alcohol, perfume, or additives, since these can be irritating. Calendula ointment and topical hyaluronic acid cream are effective for the management of radiation dermatitis. Aloe vera gel is also used, especially for prevention of skin problems.[16]

Wet desquamation of tissues generally produces pain, drainage, and increased risk of infection. Skin care to manage most desquamation includes keeping tissues clean with normal saline compresses or modified Burow's solution soaks and protected from further damage with moisture vapor–permeable dressings or Vaseline petrolatum gauze. Because protocols vary widely, the guidelines presented in Table 16-12 should be verified with your institution's radiation oncology department before using.

Chemotherapy Skin Changes. Chemotherapy produces a wide range of skin toxicities. These can range from mild erythema and hyperpigmentation to more distressing effects such as acral erythema and *erythrodysesthesia syndrome* (also called palmar-plantar erythrodysesthesia or hand-foot syndrome). Erythrodysesthesia syndrome can cause mild symptoms of redness and tingling of the palms of the hands and soles of the feet. It may also cause severe symptoms of painful moist desquamation, ulceration, blistering, and pain.

Alopecia is an easily recognizable effect of cancer therapy. It is frequently associated with varying degrees of emotional distress. Hair loss associated with radiation is local, whereas chemotherapy affects hair throughout the body. The degree and duration of hair loss experienced by patients depend on the type and dose of the chemotherapy agent.

Alopecia caused by the administration of chemotherapy agents is usually reversible. Sometimes the hair grows back while the patient is still receiving chemotherapy agents, but generally the hair does not grow back until 3 to 4 weeks after

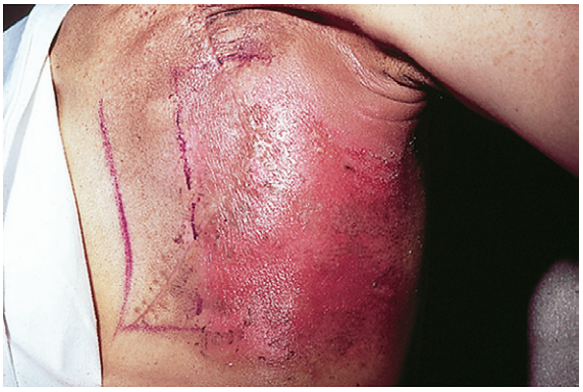

FIG. 16-15 Wet desquamation.

TABLE 16-12 PATIENT & CAREGIVER TEACHING GUIDE

Radiation Skin Reactions

Include the following instructions when teaching the patient and the caregiver to clean and protect the skin in a radiation treatment area.

1. Gently cleanse the skin in the treatment field using a mild soap (Ivory, Dove), tepid water, a soft cloth, and a gentle patting motion. Rinse thoroughly and pat dry.
2. Apply nonmedicated, nonperfumed, moisturizing lotion or cream, such as calendula ointment, aloe gel, Aquaphor, or Biafine cream, to alleviate dry skin. Some substances must be gently cleansed from the treatment field before each treatment and reapplied. Over-the-counter hydrocortisone cream 1% may reduce itching.
3. Rinse the area with saline solution. Expose the area to air as often as possible. If copious drainage is present, use astringent compresses (such as Domeboro solution) and nonadhesive absorbent dressings (they must be changed as soon as they become wet). Observe the area daily for signs of infection.
4. Avoid wearing tight-fitting clothing such as brassieres and belts over the treatment field.
5. Avoid wearing harsh fabrics, such as wool and corduroy. A lightweight cotton garment is best. If possible, expose the treatment field to air.
6. Use gentle detergents such as Dreft and Ivory Snow to wash clothing that will come in contact with the treatment field.
7. Avoid direct exposure to the sun. If the treatment field is in an area that is exposed to the sun, wear protective clothing such as a wide-brimmed hat when out in the sun and apply sunscreen lotion.
8. Avoid all sources of excessive heat (hot water bottles, heating pads, sunlamps) on the treatment field.
9. Avoid exposing the treatment field to cold temperatures (ice bags or cold weather).
10. Avoid swimming in saltwater or in chlorinated pools during the time of treatment.
11. Avoid the use of potential irritants (e.g., perfumes, powders, or cosmetics) on the skin in the treatment field; review use of other topical medications or lotions with your health care provider during treatment. Also avoid tape, dressings, and adhesive bandages unless permitted by the radiation therapist. Avoid shaving the hair in the treatment field.
12. Continue to protect sensitive skin after the treatment is completed. Do the following:
    - Avoid direct exposure to the sun. A sunscreen agent and protective clothing must be worn if the potential of exposure to the sun is present.
    - Use an electric razor if shaving is necessary in the treatment field.

the drugs are discontinued. Often the new hair has a different color and texture than the hair that was lost.

Patients experience a range of emotions at the prospect of losing their hair and when hair loss actually occurs. These may include anger, grief, embarrassment, or fear. Hair loss is a visible reminder of their cancer and the challenges of treatment. For some people, the loss of hair is one of the most stressful events experienced during the course of treatment. The American Cancer Society's "Look Good, Feel Better" program is an excellent support and resource for people experiencing not just hair loss but body image changes in general.

PULMONARY EFFECTS. Both chemotherapy and radiation have the potential to produce pulmonary tissue damage that is irreversible and progressive. Distinguishing between the complications of treatment and those related to disease is challenging. The effects of radiation on the lung include both acute and late reactions. Immediate pulmonary effects of radiation can be alarming to patients because they may mimic symptoms (e.g., cough, dyspnea) that precipitated the cancer diagnosis.

Pneumonitis is a delayed acute inflammatory reaction that may occur within 1 to 3 months after completion of thoracic radiation. This reaction is often asymptomatic, although an increase in cough, fever, and night sweats may occur. Some patients may develop pulmonary fibrosis (with or without prior pneumonitis), which is a late effect of therapy.

The most common pulmonary toxicities associated with chemotherapy include pulmonary edema (noncardiogenic) related to capillary leak syndrome or fluid retention, hypersensitivity pneumonitis, interstitial fibrosis, and pneumonitis produced by an inflammatory reaction or destruction of alveolar-capillary endothelium.

CARDIOVASCULAR EFFECTS. Radiation to the thorax can damage the pericardium, myocardium, valves, and coronary blood vessels. The pericardium is most commonly involved, with pericardial effusion or pericarditis the key problems. Patients with preexisting coronary artery disease are especially vulnerable.

Anthracyclines (e.g., doxorubicin [Adriamycin], daunorubicin) cause cardiotoxicity. Acute cardiotoxicities may cause electrocardiographic (ECG) abnormalities. Late effects of anthracyclines are left ventricular dysfunction and heart failure.

5-FU can cause cardiac ischemic syndrome. Trastuzumab (Herceptin), which is used in the treatment of breast cancer, is cardiotoxic and may result in ventricular dysfunction and heart failure. Baseline and periodic echocardiograms to monitor left ventricular function during treatment are usually done.

REPRODUCTIVE EFFECTS. Reproductive dysfunction secondary to radiation and chemotherapy varies according to the radiation treatment field and dosage, the particular chemotherapy agent and dose, and host factors (e.g., age). Treatment can cause temporary or permanent gonadal failure. Reproductive effects occur most often when reproductive organs are included in the radiation treatment field and when alkylating agents are used.

The testes are highly sensitive to radiation, and they should be protected with a testicular shield whenever possible. Pretreatment status may be a significant factor because a low sperm count and loss of motility are seen in individuals with testicular cancer and Hodgkin's lymphoma before any therapy is begun. Combined modality treatment or prior chemotherapy with alkylating agents enhances and prolongs the effects of radiation on the testes. When radiation is used alone with conventional doses and appropriate shielding, testicular recovery often occurs. Compromise of reproductive function in men may also result from erectile dysfunction after pelvic radiation.

The radiation dose that induces ovarian failure changes with age. Unlike the testes, there is no way to repair ovarian function. When radiation therapy is given, the ovaries are shielded whenever possible. Other factors that influence reproductive or sexual functioning in women include reactions in the cervix and endometrium. These tissues withstand a high radiation dose with minimal sequelae, accounting for the ability to treat endometrial and cervical cancer with high external and brachytherapy doses. Acute reactions such as tenderness, irritation, and loss of lubrication compromise sexual activity. Late effects of combined internal and external radiation therapy include vaginal shortening related to fibrosis and loss of elasticity and lubrication.

The patient and her or his partner require information about the expected effects of treatment relative to reproductive and sexual issues. Potential infertility can be a significant consequence for the individual, and counseling may be indicated. However, in no case should the patient think that conception is not possible during treatment. Pretreatment harvesting of sperm, ova, or ovarian tissue may be considered. Specific suggestions to manage side effects that have an impact on sexual functioning include using a water-soluble vaginal lubricant and routinely using a vaginal dilator after pelvic irradiation. Encourage discussion of issues related to sexuality, offer specific suggestions, and make referrals for ongoing counseling when indicated.

COPING WITH THERAPY. You have a key role in assisting patients in coping with the psychoemotional issues associated with cancer treatment. Anxiety is common—anxieties about various aspects of treatment administration (e.g., repeated venipuncture), dependency on others, ability to pay, potential side effects, and poor outcomes. Repetitive office visits or hospitalizations, continuing medications, and frequent laboratory testing force the individual to confront the cancer on a daily basis. Treatment-related uncertainties and fears are often most evident at the beginning of therapy, but anxiety may surface again when therapy is completed (e.g., fear of recurrence, less available support).

Telling patients that they will be followed and that support is ongoing can be reassuring. Providing information and support can help minimize the negative impact of cancer therapy on a person's quality of life. Patient teaching, symptom management, and interventions to help patients self-manage their illness (e.g., adjusting treatment schedules to permit patients to work when possible, making referrals to support groups) facilitate coping. Arranging for patients to meet with individuals who have successfully completed therapy can increase their hopefulness and confidence. In addition, make regular supportive telephone contacts between office visits and assist with planning for transportation, nutrition, and emotional support with available resources such as the American Cancer Society, Cancer Lifeline, churches, and other community resources.

LATE EFFECTS OF RADIATION AND CHEMOTHERAPY

Cancer survivors are achieving long-term remission and survival with advancements in treatment modalities. However, these forms of therapy (especially radiation therapy and chemotherapy) may produce long-term sequelae termed *late effects* that occur months to years after cessation of therapy. Every body system can be affected to some extent by chemotherapy or radiation therapy.

Acute radiation effects generally manifest as transient inflammatory changes in highly proliferative cells (e.g., epithelial tissues). In contrast, late radiation effects occur most commonly in post-mitotic cells (e.g., liver, kidney, lung, heart, muscle, bone, and connective tissues). Once they occur, the late effects may be progressive and generally are permanent. Examples range from skin telangiectasias to strictures, fistulas, or radiation necrosis. Alteration of the lymphatic channels (e.g., axillary lymph node dissection) may contribute to lymphedema. Secondary malignancies (particularly skin cancers) are other late radiation effects.

Long-term effects of chemotherapy include cataracts, arthralgias, endocrine alterations, renal insufficiency, hepatitis, osteoporosis, neurocognitive dysfunction, or other effects depending on the agents. The additive effects of multiagent chemotherapy before, during, or after a course of radiation therapy can significantly increase the resulting late effects.

The cancer survivor may also be at risk for secondary malignancies, including leukemia, angiosarcoma, and skin cancer. Approximately 8% of cancer survivors (most commonly breast and colon cancer survivors) face a secondary malignancy. Alkylating agents and high-dose radiation are the most frequent causes of secondary malignancies.

In general, the overall risk of developing neoplastic complications is low, and the latency period may be long. The potential risk for developing a secondary malignancy does not contraindicate the use of cancer treatment. Smoking may significantly increase the risk of secondary malignancies following some cancer treatment. Therefore counsel all patients about smoking cessation.

BIOLOGIC AND TARGETED THERAPY

Biologic and targeted therapy is the fourth cancer treatment modality. Biologic and targeted therapy can be effective alone or in combination with surgery, radiation therapy, and chemotherapy. **Biologic therapy,** or *biologic response modifier* therapy, consists of agents that modify the relationship between the host and the tumor by altering the biologic response of the host to the tumor cells. Biologic agents may affect host-tumor response in three ways: (1) they have direct antitumor effects; (2) they restore, augment, or modulate host immune system mechanisms; and (3) they have other biologic effects, such as interfering with the cancer cells' ability to metastasize or differentiate.

Targeted therapy interferes with cancer growth by targeting specific cell receptors and pathways that are important in tumor growth. Targeted therapies work at sites that are on the cell surface, at the intracellular level, or in the extracellular domain (Fig. 16-16 and Table 16-13). The targeted therapies are more selective for specific molecular targets than cytotoxic anticancer drugs. Thus they are able to kill cancer cells with less damage to normal cells compared with chemotherapy.

Targeted therapies include epidermal growth factor receptor (EGFR)–tyrosine kinase inhibitors, BCR-ABL tyrosine kinase inhibitors, CD20 monoclonal antibodies (MoAb), angiogenesis inhibitors, and proteasome inhibitors. As more oncogene targets are identified, such as BRAF (B-type Raf kinase) or ALK

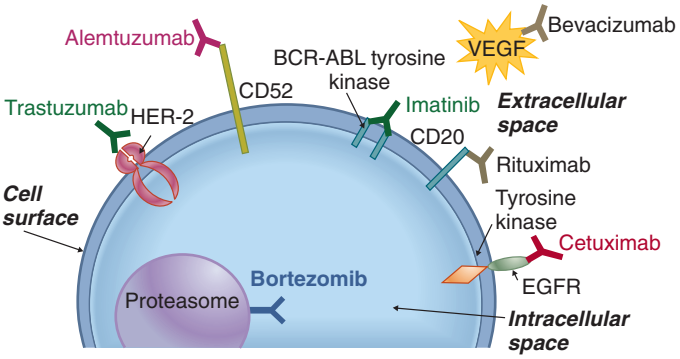

FIG. 16-16 Sites of action of targeted therapy. *EGFR,* Epidermal growth factor receptor; *HER-2,* human epidermal growth factor receptor 2; *VEGF,* vascular endothelial growth factor.

TABLE 16-13 DRUG THERAPY

Biologic and Targeted Therapy*

Drug	Mechanism of Action	Indications
α-interferon (Roferon-A, Intron A)	Inhibits DNA and protein synthesis Suppresses cell proliferation Increases cytotoxic effects of natural killer (NK) cells	Hairy cell leukemia, chronic myelogenous leukemia, malignant melanoma, renal cell carcinoma, ovarian cancer, multiple myeloma, Kaposi sarcoma
interleukin-2 (aldesleukin [Proleukin])	Stimulates proliferation of T and B cells Activates NK cells	Metastatic renal cell cancer, metastatic melanoma
BCG vaccine (TheraCys)	Induces an immune response that prevents angiogenesis of tumor	In situ bladder cancer
Epidermal Growth Factor Receptor (EGFR)–Tyrosine Kinase (TK) Inhibitors		
cetuximab (Erbitux)	Inhibits EGFR	Colorectal cancer, head and neck cancer
erlotinib (Tarceva)	Inhibits EGFR-TK	Non–small cell lung cancer, advanced pancreatic cancer
lapatinib (Tykerb)	Inhibits EGFR-TK and binds HER-2	Advanced breast cancer that is HER-2 positive
panitumumab (Vectibix)	Inhibits EGFR	Colorectal cancer
BCR-ABL Tyrosine Kinase Inhibitors		
dasatinib (Sprycel)	Inhibits BCR-ABL TK	Chronic myeloid leukemia
imatinib (Gleevec)	Inhibits BCR-ABL TK	Chronic myeloid leukemia, GI stromal tumors (GIST)
nilotinib (Tasigna)	Inhibits BCR-ABL TK	Chronic myeloid leukemia
CD20 Monoclonal Antibodies		
ibritumomab tiuxetan/yttrium-90 (Zevalin)	Binds CD20 antigen, causing cytotoxicity and radiation injury	Non-Hodgkin's lymphoma (B cell)
ofatumumab (Arzerra)	Binds CD20 antigen, causing cytotoxicity	Chronic lymphocytic leukemia
rituximab (Rituxan)	Binds CD20 antigen, causing cytotoxicity	Non-Hodgkin's lymphoma (B cell)
tositumomab/^{131}I tositumomab (Bexxar)	Binds CD20 antigen, causing immune attack and radiation injury	Non-Hodgkin's lymphoma (B cell)
Angiogenesis Inhibitors		
bevacizumab (Avastin)	Binds vascular endothelial growth factor (VEGF), thereby inhibiting angiogenesis	Colorectal cancer, non–small cell lung cancer, renal cell carcinoma
pazopanib (Votrient)	Binds VEGF, thereby inhibiting angiogenesis	Advanced renal cell carcinoma
Proteasome Inhibitors		
bortezomib (Velcade)	Inhibits proteasome activity, which functions to regulate cell growth	Multiple myeloma
carfilzomib (Kyprolis)	Inhibits proteasome activity, which functions to regulate cell growth	Multiple myeloma
Other Targeted Therapies		
alemtuzumab (Campath)	Binds CD52 antigen (found on T and B cells, monocytes, NK cells, neutrophils)	Chronic lymphocytic leukemia (B cell), GIST
axitinib (Inlyta)	Inhibits multiple TKs	Advanced renal cell carcinoma
crizotinib (Xalkori)	Inhibits anaplastic lymphoma kinase (ALK)	Locally advanced or metastatic non–small cell lung cancer that is ALK positive
everolimus (Afinitor)	Inhibits a specific protein known as the mammalian target of rapamycin (mTOR)	Advanced renal cell carcinoma, advanced breast cancer
ipilimumab (Yervoy)	Binds with CTLA-4 causing an antitumor-mediated immune response	Metastatic melanoma or unresectable melanoma
pertuzumab (Perjeta)	Binds HER-2	Breast cancer (HER-2 positive)
sorafenib (Nexavar)	Inhibits multiple TKs	Advanced renal cell carcinoma
sunitinib (Sutent)	Inhibits multiple TKs	Advanced renal cell carcinoma, GIST
temsirolimus (Torisel)	Inhibits a specific protein known as the mammalian target of rapamycin (mTOR)	Advanced renal cell carcinoma
trastuzumab (Herceptin)	Binds HER-2	Breast cancer (HER-2 positive)
vandetanib (Caprelsa)	Inhibits multiple TKs	Medullary thyroid cancer
vemurafenib (Zelboraf)	Inhibits BRAF serine threonine kinase	BRAF V600E mutated metastatic melanoma

*An enhanced version of this table listing side effects (eTable 16-7) is available on the website for this chapter.
BRAF, B-type Raf; *CTLA-4,* cytotoxic T lymphocyte antigen 4; *HER-2,* human epidermal growth factor receptor 2.

(anaplastic lymphoma kinase), agents are being developed that target specific oncogenes. Targeted therapies provide for use of personalized therapy based on the biology of an individual's tumor.[17]

EGFR is a transmembrane molecule that works through activation of intracellular tyrosine kinase (TK). Overexpression of EGFR is associated with unregulated cell growth and poor prognosis. Drugs that inhibit EGFR suppress cell proliferation and promote *apoptosis* (programmed cell death).

EGFRs belong to the same receptor family as human epidermal growth factor receptor 2 (HER-2), the target for trastuzumab (Herceptin). HER-2 is overexpressed in certain cancers (especially breast cancers) and is associated with more aggressive disease and decreased survival. Trastuzumab is a MoAb that binds to HER-2 and is given IV to inhibit the growth of breast cancer cells that overexpress the HER-2 protein. Lapatinib (Tykerb) is an oral agent used for breast cancer that overexpresses HER-2.

Chronic myeloid leukemia (CML) cells make an abnormal active enzyme called *BCR-ABL tyrosine kinase*. Drugs (e.g., imatinib [Gleevec]) that inhibit this enzyme suppress proliferation of CML cells and promote apoptosis.

Angiogenesis inhibitors work by preventing the mechanisms and pathways necessary for vascularization of tumors. Bevacizumab (Avastin), a recombinant human MoAb, binds with vascular endothelial growth factor (VEGF), a compound that stimulates blood vessel growth. When bevacizumab binds with VEGF, it prevents VEGF from binding with its receptors on vascular endothelial cells and promoting new vessel formation. As a result, further tumor growth is inhibited.

Proteasomes are intracellular multienzyme complexes that degrade proteins. In cancer cells, proteasome inhibitors (e.g., bortezomib [Velcade]) promote accumulation of proteins that lead to cell death.

Side Effects of Biologic and Targeted Therapy

The administration of one biologic agent usually induces the endogenous release of other biologic agents. The release and action of these biologic agents result in systemic immune and inflammatory responses. The toxicities and side effects of biologic agents are related to dose and schedule. (eTable 16-7 summarizes the potential side effects associated with specific biologic and targeted therapies.)

Common side effects include constitutional flu-like symptoms, including headache, fever, chills, myalgias, fatigue, malaise, weakness, photosensitivity, anorexia, and nausea. With interferon therapy, these flu-like symptoms almost invariably appear, but their severity generally decreases over time. Acetaminophen administered every 4 hours, as prescribed, often reduces the severity of the flu-like syndrome. The patient is commonly premedicated with acetaminophen in an attempt to prevent or decrease the intensity of these symptoms. In addition, large amounts of fluids help decrease the symptoms.

Tachycardia and orthostatic hypotension are also commonly reported. IL-2 and MoAbs can cause *capillary leak syndrome,* which can result in pulmonary edema. Other toxic and side effects may involve the CNS, renal and hepatic systems, and cardiovascular system. These effects are found particularly with interferons and IL-2.

A wide range of neurologic deficits has been observed with interferon and IL-2 therapy. The nature and extent of these problems are not yet completely understood. However, these problems are understandably frightening to the patient and the family, who must be taught to observe for neurologic problems (e.g., confusion, memory loss, difficulty making decisions, insomnia), report their occurrence, and institute appropriate safety and support measures.

MoAbs are administered by infusion. Patients may experience infusion-related symptoms, which can include fever, chills, urticaria, mucosal congestion, nausea, diarrhea, and myalgias. There is also a risk, although rare, of anaphylaxis associated with the administration of MoAbs. This potential exists because most MoAbs are produced by mouse lymphocytes and thus represent a foreign protein to the human body. The risk is significantly decreased with human MoAbs. Onset of anaphylaxis can occur within 5 minutes of administration and can be a life-threatening event. If this occurs, stop administration of the MoAb immediately, obtain emergency assistance, and implement resuscitation measures. (See Chapter 14 for a discussion of nursing management of anaphylaxis.)

Skin rashes are common in patients receiving EGFR inhibitors and manifest generally as erythema and acneiform-like rash that can cover up to 50% of the upper body. Angiogenesis inhibitors can cause problems of arterial thrombi, hemorrhage, hypertension, impaired wound healing, and proteinuria. Other toxicities of MoAbs include hepatotoxicity, bone marrow depression, and CNS effects. Individuals who receive rituximab may have a reactivation of hepatitis. Patients who receive trastuzumab may also experience cardiac dysfunction, especially when it is administered in higher doses or in combination with anthracycline antibiotics such as doxorubicin.

NURSING MANAGEMENT BIOLOGIC AND TARGETED THERAPY

Some problems experienced by the patient receiving biologic and targeted therapy are different from those observed with more traditional forms of cancer therapy. These effects occur more acutely and are dose limited (i.e., effects resolve when the agent is discontinued). Capillary leak syndrome and pulmonary edema are problems that require critical care nursing. Bone marrow depression occurring with biologic therapy administration is generally more transient and less severe than that observed with chemotherapy. Fatigue associated with biologic therapy can be so severe that it constitutes a dose-limiting toxicity. As these agents are increasingly combined with cytotoxic therapies, the spectrum of therapy-related effects expands.

Nursing interventions for flu-like syndrome include the administration of acetaminophen before treatment and every 4 hours after treatment. IV meperidine (Demerol) has been used to control the severe chills or rigors associated with some biologic agents. Other nursing measures include monitoring vital signs and temperature, planning for periods of rest for the patient, assisting with activities of daily living (ADLs), and monitoring for adequate oral intake.

Many new targeted therapies are being developed and used more frequently. You need to become familiar with side effects associated with each agent.

HEMATOPOIETIC GROWTH FACTORS

Hematopoietic growth factors are used to support cancer patients through the treatment of the disease (Table 16-14). Colony-stimulating factors (CSFs) are a family of glycoproteins

TABLE 16-14 DRUG THERAPY

Hematopoietic Growth Factors Used in Cancer Treatment

Growth Factor	Drug Name	Indications	Side Effects
Granulocyte-macrophage colony-stimulating factor (GM-CSF)	sargramostim (Leukine)	Myeloid cell recovery after bone marrow transplantation	Nausea, vomiting, diarrhea, fever, chills, myalgia, headache, fatigue
Granulocyte colony-stimulating factor (G-CSF)	filgrastim (Neupogen), pegfilgrastim (Neulasta), tbo-filgrastim	Chemotherapy-induced neutropenia	Bone pain, nausea, vomiting
Erythropoietin	epoetin α (Epogen, Procrit)	Anemia of chronic cancer	Hypertension, thrombosis, headache
	darbepoetin α (Aranesp)	Anemia related to chemotherapy	Hypertension, thrombosis, headache
Interleukin-11 (platelet growth factor)	oprelvekin (Neumega)	Thrombocytopenia related to chemotherapy	Fluid retention, peripheral edema, dyspnea, tachycardia, nausea, mouth sores

produced by various cells. CSFs stimulate production, maturation, regulation, and activation of cells of the hematologic system. The name of the CSF is based on the specific cell line it affects (see Table 16-14).

Erythropoiesis-stimulating agents (ESAs) should be used only when treating anemia specifically caused by chemotherapy. ESA use is avoided in patients receiving chemotherapy with the intent to cure the disease. Use of these agents has raised safety concerns because they can cause thromboembolic events and increase the risk for death and for serious cardiovascular events when administered to achieve a target hemoglobin of greater than 12 g/dL. Therefore the lowest dose should be used that will gradually increase hemoglobin to the lowest level sufficient to avoid the need for blood transfusion. Monitor the hemoglobin level regularly.

HEMATOPOIETIC STEM CELL TRANSPLANTATION

Bone marrow transplantation (BMT) and **peripheral stem cell transplantation (PSCT)** are effective, lifesaving procedures for the treatment of a number of malignant and nonmalignant diseases (Table 16-15). BMT and PSCT allow for the safe use of very high doses of chemotherapy agents and/or radiation therapy in patients whose tumors have developed resistance or failed to respond to standard doses of chemotherapy and radiation. Although these procedures are lifesaving, patients may have long-term or delayed complications that can affect their quality of life.[18,19]

This therapeutic approach was typically referred to as BMT because the bone marrow was the original source of stem cells when the procedure was first developed. However, advances in harvesting and cryopreservation technologies have opened new pathways to the collection of stem cells from the peripheral blood. Consequently, the terminology has changed, and the procedure is now referred to as **hematopoietic stem cell transplantation (HSCT).** Whether the diagnosis is a malignant or nonmalignant disease, the goal of HSCT is cure. Overall cure rates are still low but are steadily increasing. Even when cure is not achieved, transplantation can result in a period of remission.

TABLE 16-15 INDICATIONS FOR HEMATOPOIETIC STEM CELL TRANSPLANTATION

Malignant Diseases
- Acute and chronic myelogenous leukemia
- Acute lymphocytic leukemia
- Hodgkin's lymphoma
- Multiple myeloma
- Myelodysplastic syndrome
- Neuroblastoma
- Non-Hodgkin's lymphoma
- Ovarian cancer
- Sarcoma
- Testicular cancer

Nonmalignant Diseases
- Hematologic diseases
- Aplastic anemia
- Chronic granulomatous disease
- Fanconi's anemia
- Sickle cell disease (severe)
- Thalassemia
- Immunodeficiency diseases
- Severe combined immunodeficiency disease (SCID)
- Wiskott-Aldrich syndrome

The approach in HSCT is to eradicate diseased tumor cells and/or clear the marrow of its components to make way for engraftment of the transplanted, healthy stem cells. This is accomplished by administering higher than usual dosages of chemotherapy with or without radiation therapy, which can produce life-threatening consequences associated with pancytopenia and other adverse effects. After chemotherapy and radiation therapy are completed, healthy stem cells are infused. These healthy stem cells "rescue" the damaged bone marrow through subsequent proliferation and differentiation of the donated stem cells in the recipient.

HSCT is an intensive procedure with many risks. Some patients die from treatment-related complications or from recurrence of the original disease. Because it is a highly toxic therapy, the patient must weigh the significant risks of treatment-related death or treatment failure (relapse) against the hope of cure.

Types of Hematopoietic Stem Cell Transplants

HSCTs are categorized as allogeneic, syngeneic, or autologous. The sources of stem cells include the bone marrow, peripheral circulating blood, and umbilical cord blood. In *allogeneic transplantation,* stem cells are acquired from a donor who, through human leukocyte antigen (HLA) tissue typing, has been determined to be HLA matched to the recipient. HLA typing involves testing WBCs to identify genetically inherited antigens common to both donor and recipient that are important in compatibility of transplanted tissue. (HLA tissue typing is discussed in Chapter 14.) The donor is often a family member but may be an unrelated donor found through a national or international bone marrow registry (e.g., National Marrow Donor Program). Although more risks and toxicities may be associated with an unrelated allogeneic transplant, a benefit of this type of transplant is that it not only eradicates tumor cells with high-dose therapy, but also may stimulate the graft-versus-tumor effect in which donor WBCs identify and attack malignant cells in the

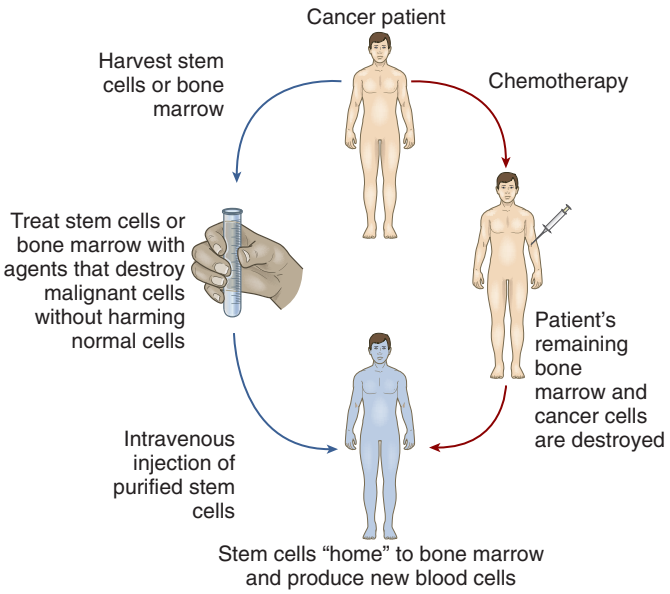

FIG. 16-17 Autologous stem cell transplant.

recipient. Common indications for allogeneic transplant are certain leukemias, multiple myeloma, and lymphoma.

Syngeneic transplantation is a type of allogeneic transplant that involves obtaining stem cells from one identical twin and infusing them into the other. Identical twins have identical HLA types and are a perfect match. Therefore neither the graft-versus-host nor the graft-versus-tumor effect occurs.

In *autologous transplantation*, patients receive their own stem cells back after *myeloablative* (destroying bone marrow) chemotherapy (Fig. 16-17). The aim of this approach is purely "rescue." It enables patients to receive intensive chemotherapy and/or radiation by supporting them with their previously harvested stem cells until their marrow generates blood cells again on its own. Restoration usually takes about 4 to 6 weeks. Autologous transplants are typically used to treat hematologic malignancies if there is no suitable donor or the patient cannot undergo allogeneic transplantation.

The newer, nonmyeloablative or reduced intensity transplant uses lower doses of radiation or chemotherapy that result in less toxicity and myelosuppression. HSCT continues to be investigated in the management of some solid tumors refractory to treatment.

Procedures

Harvest Procedures. Hematopoietic stem cells are *harvested* from a donor (for allogeneic transplantation) or from the recipient (for autologous transplantation) via two different methods. In one type of procedure, used for harvesting stem cells residing in bone marrow (as the process was originally developed), the procedure is performed in the operating room using general or spinal anesthesia. Multiple bone marrow aspirations (usually from the iliac crest, but sometimes from the sternum) are carried out to obtain stem cells. The entire bone marrow harvest procedure takes about 1 to 2 hours, and the patient can be discharged after recovery. Post-harvest, the donor may experience pain at the collection site that lasts up to 7 days and can be treated with mild analgesics. The donor's body will replenish the removed bone marrow in a few weeks.

In the other type of procedure, peripheral stem cell transplants are obtained from the peripheral blood in an outpatient procedure. It is done using cell separator equipment that automatically separates the stem cells from the blood circulating through the machine and returns the remaining blood components to the donor. The process averages about 2 to 4 hours but can sometimes take longer depending on donor factors and the quality of the venous access. Often it takes more than one procedure to obtain enough stem cells. Because the blood has fewer stem cells than the bone marrow, "mobilization" of stem cells from the bone marrow into the peripheral blood can be accomplished using chemotherapy and/or hematopoietic growth factors.

Common growth factors that are used are granulocyte-macrophage colony-stimulating factor (GM-CSF) and granulocyte colony-stimulating factor (G-CSF) (see Table 16-14), but chemotherapy agents, typically cyclophosphamide, can also be used if there is a need to reduce tumor burden. When patients are given growth factors for mobilization, stem cells are harvested after 4 or 5 days of growth factor injections.

Plerixafor (Mozobil) is a drug given subcutaneously that, when used in combination with G-CSF, boosts the number of stem cells released from the bone marrow into the bloodstream. Plerixafor is intended to be used in combination with G-CSF for treatment of multiple myeloma or non-Hodgkin's lymphomas; it is not to be used for leukemia.

Harvested marrow is processed to strain out bone fragments (this is not necessary with peripheral collections). The marrow or peripherally collected stem cells are then bagged with preservative for cryopreservation and storage until they are needed, or they are used immediately. Since it is coming from the patient, autologous stem cells are sometimes treated (purged) to remove undetected cancer cells. Many different pharmacologic, immunologic, physical, and chemical agents have been used for this purpose.

Umbilical cord blood is also rich in hematopoietic stem cells, and successful allogeneic transplants have been performed using this source. Cord blood can be HLA-typed and cryopreserved. A disadvantage of cord blood is the possibility of insufficient numbers of stem cells to permit transplant to adults. Considerable research is currently ongoing to define the optimal application of this technology.

Preparative Regimens and Stem Cell Infusions. In malignant diseases, patients receive myeloablative dosages of chemotherapy with or without adjunctive radiation to treat underlying disease. Total-body irradiation (TBI) can be used for immunosuppression or to treat the disease. These preparative therapies are known as the *conditioning regimen.*

The timing of stem cell harvest and reinfusion is critical, particularly with autologous transplantation. To ensure the collection of optimally functioning stem cells in adequate numbers, conditioning is begun only after stem cells have already been harvested. They are thawed and reinfused only after chemotherapy has been eliminated from the body (i.e., usually about 24 to 48 hours) to avoid damage to newly infused cells.

Stem cell infusions are administered IV, and can be injected via the slow bolus method or infused much like a blood transfusion. The infused stem cells reconstitute the bone marrow elements, "rescuing" the recipient's hematopoietic system. Usually 2 to 4 weeks are required for the transplanted marrow to start producing hematopoietic blood cells. During this period, when the patient has pancytopenia, it is critical to

protect the patient from exposure to infectious agents and support the patient with electrolyte supplements, nutrition, and blood component transfusions (as needed) to maintain adequate levels of circulating RBCs and platelets.

Complications. Bacterial, viral, and fungal infections are common after HSCT. Prophylactic antibiotic therapy may reduce their incidence. A potentially serious complication of allogeneic transplant is graft-versus-host disease. This occurs when the T lymphocytes from the donated marrow (graft) recognize the recipient (host) as foreign and begin to attack certain organs such as the skin, liver, and GI tract. (Graft-versus-host disease is discussed in Chapter 14.) The occurrence and severity of posttransplant complications also depend on the drugs used in the patient's particular conditioning regimen (some are more toxic than others) and the stem cell source. Because stem cells in the peripheral blood are more mature than those harvested from the marrow, the hematologic recovery period in PSCT is shorter, and fewer, less severe complications are seen.

TABLE 16-16 NUTRITIONAL THERAPY

Protein Foods With High Biologic Value

Milk

Whole milk (1 cup) = 9 g protein

Double-strength milk: 1 quart of whole milk plus 1 cup of dried skim milk blended and chilled: 1 cup = 14 g protein

Milk shake: 1 cup of ice cream plus 1 cup of milk = 15 g protein, 416 calories

Use evaporated milk, double-strength milk, or half-and-half to make casseroles, hot cereals, sauces, gravies, puddings, milk shakes, and soups.

Yogurt (regular and frozen): check labels and purchase brand with highest protein content: 1 cup = 10 g protein

Eggs

Egg = 6 g protein

Eggnog (1 cup) = 15.5 g protein

Add eggs to salads, casseroles, and sauces. Deviled eggs are especially well tolerated.

Desserts that contain eggs include angel food cake, sponge cake, custard, and cheesecake.

Cheese

Cottage	½ cup	15 g protein
American	1 slice	3 g protein
Cheddar	1 slice	6 g protein
Cream	1 tbs	1 g protein

Use cheese in a sandwich or as a snack.

Add cheese to salads, casseroles, sauces, and baked potatoes.

Cheese spread with crackers is a wholesome snack that can be made and stored in the refrigerator for easy accessibility.

Advise patient that cheese can be constipating.

Meat, Poultry, Fish

Pork	3 oz	approx. 19 g protein
Chicken	½ breast	approx. 26 g protein
Fish	3 oz	approx. 30 g protein
Tuna fish	6½ oz	approx. 44.5 g protein

Add meat, poultry, and fish to salads, casseroles, and sandwiches.

Add strained and junior baby meats to soups and casseroles.

Cocktail wieners and deviled ham on crackers are wholesome snacks. These snacks can be made and stored in the refrigerator for easy accessibility.

GENE THERAPY

Gene therapy is an experimental therapy that involves introducing genetic material into a person's cells to fight disease. At this time, the use of gene therapy is investigational. Additional information can be found at *http://ghr.nlm.nih.gov/handbook/therapy.pdf*. (Gene therapy is discussed in Chapter 13.)

COMPLICATIONS RESULTING FROM CANCER

The patient may develop complications related to the continual growth of the malignancy into normal tissue or to the side effects of treatment.

NUTRITIONAL PROBLEMS

Malnutrition

The patient with cancer may experience protein and calorie malnutrition characterized by fat and muscle depletion. (Assessment of malnutrition is discussed in Chapter 40.)

Soft, nonirritating high-protein and high-calorie foods should be eaten throughout the day. Foods suggested for increasing the protein intake are presented in Table 16-16. High-calorie foods that provide energy and minimize weight loss are presented in Table 16-17. (A sample high-calorie, high-protein diet is presented in Table 40-10.)

Teach the patient to avoid extremes of temperature, tobacco, alcohol, spicy or rough foods, and other irritants. Encourage nutritional supplements (e.g., Ensure) as an adjunct to meals and fluid intake. Weigh the patient at least twice each week to monitor for weight loss.

Suggest a referral for individualized nutritional counseling to the patient or the health care provider as soon as a 5% weight loss is noted or if the patient has the potential for protein and calorie malnutrition. Monitor albumin and prealbumin levels. Once a 10-lb (4.5-kg) weight loss occurs, it is difficult to maintain the nutritional status.

Teach the patient to use nutritional supplements in place of milk when cooking or baking. Foods to which nutritional supplements can be easily added include scrambled eggs, pudding, custard, mashed potatoes, cereal, and cream sauces. Packages of Instant Breakfast can be used as indicated or sprinkled on cereals, desserts, and casseroles.

Families are an integral part of the health care team. As symptom severity increases, the family's role in helping the patient eat becomes increasingly critical.

TABLE 16-17 NUTRITIONAL THERAPY

High-Calorie Foods

Mayonnaise	1 tbs	=	101 cal
Butter or margarine	1 tsp	=	35 cal
Sour cream	1 tbs	=	72 cal
Peanut butter	1 tbs	=	94 cal
Whipped cream	1 tbs	=	53 cal
Corn oil	1 tbs	=	119 cal
Jelly	1 tbs	=	49 cal
Ice cream	1 cup	=	256 cal
Honey	1 tbs	=	64 cal

If the malnutrition cannot be treated with dietary intake, it may be necessary to use enteral or parenteral nutrition. (Enteral and parenteral nutrition are discussed in Chapter 40.)

Altered Taste Sensation (Dysgeusia)

Cancer cells may release substances that stimulate the bitter taste buds. The patient may also experience an alteration in the sweet, sour, and salty taste sensations. Meat may taste bitter or bland. At this time, the physiologic basis of these varied taste alterations is unknown.

Teach the patient with an altered taste problem to avoid foods that are disliked. Frequently the patient may feel compelled to eat certain foods that are believed to be beneficial. Tell the patient to experiment with spices and other seasoning agents in an attempt to mask the taste alterations. Lemon juice, onion, mint, basil, and fruit juice marinades may improve the taste of certain meats and fish. Bacon bits, onion, and ham may enhance the taste of vegetables. Increasing the amount of spice or seasoning agent is usually not an effective way to enhance the taste.

INFECTION

Infection is a primary cause of death in the patient with cancer. The usual sites of infection include the lungs, GU system, mouth, rectum, peritoneal cavity, and blood (septicemia). Infection occurs as a result of the ulceration and necrosis caused by the tumor, compression of vital organs by the tumor, and neutropenia caused by the disease process or the treatment of cancer.

Instruct patients with a risk for neutropenia to call their health care provider if they have a temperature of 100.4° F (38° C) or greater. Assessment most often includes signs and symptoms of fever, determination of possible etiology (e.g., sinuses, mucous membranes, respiratory, GI, urinary, sites of any tubes or lines), and complete blood count.

Many patients are neutropenic when an infection develops. In these individuals, infection may cause significant morbidity and may be rapidly fatal if not treated promptly. The classic manifestations of infection are often subtle or absent in a patient with neutropenia and a depressed immune system. (Neutropenia is discussed in Chapter 31.)

ONCOLOGIC EMERGENCIES

Oncologic emergencies are life-threatening emergencies that can occur as a result of cancer or cancer treatment. These emergencies can be obstructive, metabolic, or infiltrative.

Obstructive Emergencies

Obstructive emergencies are primarily caused by tumor obstruction of an organ or blood vessel. Obstructive emergencies include superior vena cava syndrome, spinal cord compression syndrome, third space syndrome, and intestinal obstruction. (Chapter 43 presents a discussion of intestinal obstruction.)

Superior Vena Cava Syndrome. *Superior vena cava syndrome* (SVCS) results from obstruction of the superior vena cava by a tumor or thrombosis. The clinical manifestations include facial edema; periorbital edema; distention of veins of the head, neck, and chest (Fig. 16-18); headache; and seizures. A mediastinal mass is often visible on chest x-ray. The most common causes are lung cancer, non-Hodgkin's lymphoma, and metastatic breast cancer. The presence of a central venous catheter and previous radiation therapy to the mediastinum increase the risk for development of SVCS.

FIG. 16-18 Superior vena caval obstruction in bronchial carcinoma. Note the swelling of the face and neck and the development of collateral circulation in the veins.

SVCS is considered a serious medical problem. Management usually involves radiation therapy to the site of obstruction. However, chemotherapy may be administered for tumors more sensitive to this form of therapy.

Spinal Cord Compression. *Spinal cord compression* (SCC) is a neurologic emergency caused by a malignant tumor in the epidural space of the spinal cord. The most common cancers that cause this problem are breast, lung, prostate, GI, and renal tumors and melanomas. Lymphomas also pose a risk if diseased lymph tissue invades the epidural space.

Symptoms of SCC are back pain that is intense, localized, and persistent, accompanied by vertebral tenderness and aggravated by the Valsalva maneuver; motor weakness and dysfunction; sensory paresthesia and loss; and autonomic dysfunction. One of the clinical symptoms that reflects autonomic dysfunction is a reported change in bowel or bladder function.

The use of radiation therapy in conjunction with corticosteroids is generally associated with some initial improvement. Surgical decompressive laminectomy is used for those with tumors that are not responsive to radiation or when the tumor is in a previously irradiated area. Activity limitations and pain management are important nursing interventions.

Third Space Syndrome. *Third space syndrome* involves a shifting of fluid from the vascular space to the interstitial space that generally occurs secondary to extensive surgical procedures, biologic therapy, or septic shock. Initially patients exhibit signs of hypovolemia, including hypotension, tachycardia, low central venous pressure, and decreased urine output. Treatment includes fluid, electrolyte, and plasma protein replacement. During recovery hypervolemia can occur, resulting in hypertension, elevated central venous pressure, weight gain, and shortness of breath. Treatment generally involves reduction in fluid administration and fluid balance monitoring.

Metabolic Emergencies

Metabolic emergencies are caused by the production of ectopic hormones directly from the tumor or are secondary to metabolic alterations caused by the tumor or by cancer treatment.

Ectopic hormones arise from tissues that do not normally produce these hormones. Cancer cells return to a more embryonic form, thus allowing the cells' stored potential to become evident.

Metabolic emergencies include syndrome of inappropriate antidiuretic hormone secretion, hypercalcemia, tumor lysis syndrome, septic shock, and disseminated intravascular coagulation. (Septic shock is discussed in Chapter 67, and disseminated intravascular coagulation is discussed in Chapter 31.)

Syndrome of Inappropriate Antidiuretic Hormone Secretion. Syndrome of inappropriate antidiuretic hormone (SIADH) results from abnormal or sustained production of antidiuretic hormone (ADH) by tumor cells with resultant water retention and hyponatremia (hypotonic hyponatremia) (see Chapter 50).

SIADH occurs most frequently in carcinoma of the lung (especially small cell lung cancer), but can also occur in cancer of the pancreas, duodenum, brain, esophagus, colon, ovary, prostate, bronchus, and nasopharynx; leukemia; and Hodgkin's lymphoma. Cancer cells in these tumors are actually able to manufacture, store, and release ADH. Many chemotherapy agents may also contribute to ectopic ADH production, or potentiate ADH effects, including vincristine, cyclophosphamide, vinblastine, and cisplatin.[20]

Symptoms of SIADH include weight gain without edema, weakness, anorexia, nausea, vomiting, personality changes, seizures, oliguria, decrease in reflexes, and coma. Treatment of SIADH includes treating the underlying malignancy and measures to correct the sodium-water imbalance, including fluid restriction, oral salt tablets or isotonic (0.9%) saline administration, and, in severe cases, IV administration of 3% sodium chloride solution. Furosemide (Lasix) may also be a helpful treatment in the initial phases of SIADH. Demeclocycline (Declomycin) may be needed on an ongoing basis for moderate SIADH. Monitor the sodium level because correcting SIADH rapidly may result in seizures or death.

Hypercalcemia. Hypercalcemia can occur in metastatic disease of the bone or multiple myeloma, or when a parathyroid hormone–like substance is secreted by cancer cells. It occurs in approximately 10% to 20% of patients with advanced cancer.[21] Hypercalcemia resulting from malignancies that have metastasized occurs most frequently in patients with lung, breast, kidney, colon, ovarian, or thyroid cancer. Hypercalcemia resulting from secretion of parathyroid hormone–like substance occurs most frequently in squamous cell carcinoma of the lung; head and neck, cervical, and esophageal cancer; lymphomas; and leukemia. Immobility and dehydration can contribute to or exacerbate hypercalcemia.

The primary manifestations of hypercalcemia include apathy, depression, fatigue, muscle weakness, ECG changes, polyuria and nocturia, anorexia, nausea, and vomiting. Serum levels of calcium in excess of 12 mg/dL (3 mmol/L) often produce symptoms, and significant calcium elevations can be life threatening.

Serum calcium levels are affected by a low albumin level. A low albumin level will give a false-normal calcium level. Therefore the calcium level must be corrected for serum albumin values, or an ionized calcium level should be obtained.

Chronic hypercalcemia can result in nephrocalcinosis and irreversible renal failure. The long-term treatment of hypercalcemia is aimed at the primary disease. Acute hypercalcemia is treated by hydration (3 L/day) and bisphosphonate therapy. When hydration therapy is used in the frail or older adult, diuretics (particularly loop diuretics) may be used to avoid heart failure or edema. Bisphosphonates (the mainstay of treatment) are drugs that inhibit the action of osteoclasts and therefore reduce serum calcium levels. Infusion of the bisphosphonate zoledronate (Zometa) or pamidronate (Aredia) is the treatment of choice. Bisphosphonates are also used to prevent bone complications in patients with bone metastasis.

Tumor Lysis Syndrome. Acute *tumor lysis syndrome* (TLS) is a metabolic complication characterized by rapid release of intracellular components in response to chemotherapy. It occurs less commonly with radiation therapy. TLS is often associated with large tumors that have high growth rates and are sensitive to the effects of chemotherapy.[22] Massive cell destruction, associated with aggressive chemotherapy for rapidly growing tumors, releases a host of intracellular components into the bloodstream, including potassium, phosphate, and DNA and RNA components (which are metabolized to uric acid by the liver).

A rise in serum phosphate drives serum calcium levels down, with resultant hypocalcemia. Metabolic abnormalities and concentrated uric acid (which crystallizes in the distal tubules of the kidneys) lead quickly to acute renal failure if not identified and treated early.

The four hallmark signs of TLS are hyperuricemia, hyperphosphatemia, hyperkalemia, and hypocalcemia. Early symptoms include weakness, muscle cramps, diarrhea, nausea, and vomiting. TLS usually occurs within the first 24 to 48 hours after the initiation of chemotherapy and may persist for approximately 5 to 7 days.

The primary goal of TLS management is preventing renal failure and severe electrolyte imbalances. Patients at risk for TLS should be identified early, and preventive measures implemented concurrently with chemotherapy. The primary treatment includes increasing urine production using hydration therapy and decreasing uric acid concentrations using allopurinol.

Infiltrative Emergencies

Infiltrative emergencies occur when malignant tumors infiltrate major organs or secondary to cancer therapy. The most common infiltrative emergencies are cardiac tamponade and carotid artery rupture.

Cardiac Tamponade. *Cardiac tamponade* results from fluid accumulation in the pericardial sac, constriction of the pericardium by tumor, or pericarditis secondary to radiation therapy to the chest. Manifestations include a heavy feeling over the chest, shortness of breath, tachycardia, cough, dysphagia, hiccups, hoarseness, nausea, vomiting, excessive perspiration, decreased level of consciousness, distant or muted heart sounds, and extreme anxiety. Emergency management is aimed at reduction of fluid around the heart and includes surgical establishment of a pericardial window or an indwelling pericardial catheter. Supportive therapy includes administration of oxygen therapy, IV hydration, and vasopressor therapy.

Carotid Artery Rupture. Rupture of the carotid artery occurs most frequently in patients with cancer of the head and neck secondary to invasion of the arterial wall by tumor or to erosion following surgery or radiation therapy. Bleeding can manifest as minor oozing to spurting of blood in the case of a "blowout" of the artery. In the presence of a blowout, apply pressure to the site with a finger. IV fluids and blood products are administered in an attempt to stabilize the patient for surgery. Surgical

management involves ligation of the carotid artery above and below the rupture site and reduction of local tumor.

CANCER PAIN

Moderate to severe pain occurs in approximately 50% of patients who are receiving active treatment for their cancer and in 80% to 90% of patients with advanced cancer. What is concerning is that these statistics have not changed in the past 30 years. Undertreatment of cancer pain is common and causes needless suffering, decreases quality of life, and increases the burden on family caregivers.[23]

Pain Assessment

Inadequate pain assessment is the single greatest barrier to effective pain management. Data such as vital signs and patient behaviors are not reliable indicators of pain, especially long-standing, chronic pain. It is important to distinguish between persistent and episodic, positional, or breakthrough pain. Therefore it is essential that a comprehensive pain assessment include a detailed history to elicit the following characteristics of pain: quality, location, intensity, duration, and precipitating and alleviating factors. Differentiating between types of pain (e.g., visceral, bone, neuropathic) is important in developing an effective pain management plan.

Assess pain on an ongoing basis to determine the effectiveness of the treatment plan. Obtain data and document at regular intervals the location and intensity of the pain, what it feels like, and how it is relieved. Assess change in pain (e.g., a significant change in the intensity, character, or location of pain) to determine the cause (e.g., progression of disease).

Always believe the patient report and accept it as the primary source of assessment data. Table 16-18 presents assessment questions that may facilitate data collection.

Pain Management

Pain management for the cancer patient needs to address both persistent and breakthrough components of pain if they are present. Adjuvant therapies need to be developed specific to the type or nature of the pain. In addition, teach patients how to keep a pain management diary.

Drug therapy, including nonsteroidal antiinflammatory drugs, opioids, and adjuvant pain medications, should be used and selected based on the character and/or cause of the pain. Opioids normally are prescribed for the treatment of moderate to severe cancer pain. Analgesic medications (e.g., morphine, fentanyl) should be given on a regular schedule (around the clock) with additional doses available as needed for breakthrough pain. In general, oral administration of the medication is preferred, but other routes (e.g., transdermal, transmucosal) are also available.

It is critical for you to pay attention to common side effects of pain medications (e.g., constipation) to ensure the patient's well-being and adherence with the pain management program. Nonsteroidal antiinflammatories (acetaminophen, ibuprofen) often serve as helpful adjuncts to opioid therapy, particularly for bone pain. Other adjuvant therapies, such as antidepressant and antiseizure drugs, may beneficial in neuropathic pain, which is often resistant to opioids.

Radiopharmaceuticals (e.g., samarium-153) may benefit patients with diffuse bone pain (particularly if no further chemotherapy is planned). Patients may experience an initial pain *flare* after administration. Nerve blocks or epidural or intrathecal analgesia may also be used to treat patients with unrelieved pain or to minimize the requirements for opioids.

Remember that with opioid drugs (e.g., morphine) the appropriate dosage is whatever is necessary to control the pain with the fewest side effects. Fear of addiction is not warranted. However, it must be addressed as part of patient teaching, since it is a significant barrier for both patients and nurses in appropriate pain management. Discuss the goals of analgesic therapy with patients, especially those requiring large or chronic doses of opioids. Treatment plans should be developed that balance analgesia and side effects to maintain optimal functional status.

Patient teaching should clarify myths and misconceptions and reassure patients and family caregivers that cancer pain can be effectively relieved. Furthermore, addiction and tolerance are not problems associated with effective cancer pain management. Nondrug interventions, including relaxation therapy and imagery, can be effectively used to manage pain (see Chapter 7). Additional strategies to relieve pain are discussed in Chapter 9.

TABLE 16-18 PAIN ASSESSMENT IN CANCER PATIENTS

Characteristic	Questions to Ask
Location	• Where is the pain? • Is the pain in more than one place? Is the pain in a new location? • Does location of pain correlate with known diagnosis?
Intensity	• How bad is the pain? • Rate the pain on a scale of 0-10. (See Chapter 9 for rating scales.)
Quality	• What does the pain feel like—sharp, dull, burning, shooting, aching, or other? (See Chapter 9 for descriptors.)
Pattern	• Has the pain changed? • Is the pain getting better, worse, or unchanged? • What makes the pain better or worse?
Relief measures	• What do you do to control your pain? • Do you use medications? • Do the relief measures help much? How much?

PSYCHOLOGIC SUPPORT

Psychologic support of a patient with cancer is an important aspect of cancer care. The patient may experience a variety of psychosocial concerns, including fears of dependency, loss of control, family and relationship stress, financial burden, and fear of death. Distress may be experienced at many points throughout the cancer continuum, including at diagnosis, during or after treatment, and in association with long-term follow-up visits.

Adaptation and coping with a cancer diagnosis may be influenced by a variety of patient factors, including demographics, prior coping skills and strategies, social support, and religious and spiritual beliefs (Table 16-19). You are in a key position to assess the patient's and family's responses and support positive coping strategies.

To facilitate the development of effective coping and to support the patient and the family during the various stages of cancer, you should do the following.

TABLE 16-19 FACTORS AFFECTING HOW PATIENTS COPE WITH CANCER

Factor	Description
Ability to cope with stressful events in the past	How patients coped with previous stressful events (e.g., loss of job, major disappointment, significant traumatic event) affects how they cope with diagnosis of cancer.
Availability of significant others	Patients who have effective support systems cope more effectively than those who do not.
Ability to express feelings and concerns	Patients who express feelings and needs and ask for help cope more effectively than those who internalize feelings and needs.
Age at the time of diagnosis	Age determines coping strategies to a great degree. For example, a young mother with cancer may have concerns that differ from those of a 70-year-old woman with cancer.
Extent of disease	Cure or control of the disease process is usually easier to cope with than the reality of terminal illness.
Disruption of body image	Disruption of the body image (e.g., radical neck dissection, alopecia, mastectomy) may intensify the psychologic impact of cancer.
Presence of symptoms	Symptoms such as fatigue, nausea, diarrhea, and pain may intensify the psychologic impact of cancer.
Past experience with cancer	Negative experiences with cancer (personal or in others) influence perceptions about the current situation.
Attitude associated with the cancer	Patients who feel in control and have a positive attitude about cancer and cancer treatment cope better with the diagnosis and treatment of cancer than those who feel hopeless, helpless, and out of control.

- Be available and continue to be available, especially during difficult times.
- Exhibit a caring attitude.
- Listen actively to fears and concerns.
- Help provide relief from distressing symptoms.
- Provide essential information regarding cancer and cancer care that is accurate and establishes realistic expectations about what the patient will experience.
- Maintain a relationship based on trust and confidence. Be open, honest, and caring in the approach.
- Use touch to exhibit caring. A squeeze of the hand or a hug may at times be more effective than words.
- Assist the patient in setting realistic, reachable short-term and long-term goals.
- Assist the patient in maintaining usual lifestyle patterns.
- Maintain hope, which is the key to effective cancer care. Hope varies, depending on the patient's status—hope that the symptoms are not serious, hope that the treatment is curative, hope for independence, hope for relief of pain, hope for a longer life, hope to achieve meaningful goals, or hope for a peaceful death. Hope provides control over what is occurring and is the basis of a positive attitude toward cancer and cancer care.

Many patients with cancer benefit from a variety of psychosocial interventions, such as supportive listening, stress management techniques, individual or group counseling, and cognitive-behavioral therapy. Assess the psychosocial concerns and emotional responses of patients and their families so you can connect patients with appropriate supportive care resources. Organizations are listed in the Resources section at the end of this chapter. In many cities, local units of the American Cancer Society provide a wide variety of services.

ETHICAL/LEGAL DILEMMAS

Medical Futility

Situation

D.M., a 65-year-old Jewish woman, has breast cancer with metastasis to the liver and bone. The family asks you why their mother is not receiving chemotherapy. In addition, they want to make sure that she will be resuscitated should her heart stop. They are aware of her diagnosis and that she may have only a few months to live. In morning rounds you were told that D.M. does not want any treatment that would prolong her life.

Ethical/Legal Points for Consideration

- Although court decisions have varied, legally there is substantial consensus concerning right to privacy (a constitutional right), right to informed consent and refusal of treatment, and rights pertaining to end-of-life decision making.
- A patient who is an adult and is competent (defined as capable of understanding and interpreting information and making choices) solely retains the right to make personal health care decisions.
- The Patient Self-Determination Act requires that the patient be asked on admission whether he or she has an advance directive. It is placed in the medical record if available. If the patient does not have an advance directive, it must be documented.
- Often families have difficulty accepting the finality of a terminal diagnosis.
- Sometimes family members have conflicting interests (e.g., finances, property, inheritance rights) that influence their decision-making abilities.

Discussion Questions

1. How can you help D.M. communicate her wishes to her family?
2. How can you and the health care team assist the family in planning end-of-life care that incorporates the wishes of their mother?
3. What are the cultural issues in D.M.'s case?

GERONTOLOGIC CONSIDERATIONS

CANCER

Cancer is usually a disease of aging, with most cancers occurring in people over age 65. The cancer mortality rate is exceedingly high in older adults, with 70% of all deaths due to malignancies occurring in those over age 65. This is especially important since the normal life span is lengthening and the proportion of the population who are older than 65 years is increasing.[24,25]

Clinical manifestations of cancer in older adults may be mistakenly attributed to age-related changes and ignored by the person.[25] Older adults are particularly vulnerable to the complications of both cancer and cancer therapy. This is due to their decline in physiologic functioning, social and emotional resources, and cognitive function.

The older adult's functional status should be taken into consideration when developing a treatment plan. Age alone is not a good predictor of tolerance or response to treatment. Advances in the treatment of cancer are making cancer therapies beneficial to an increasing number of older adults, including patients with suboptimal health.

Conduct a Comprehensive Geriatric Assessment (CGA) at the time of diagnosis to identify important issues that might

affect decisions about treatment options. Issues to assess include projected life expectancy, estimate of morbidity from cancer, co-morbidities that would affect treatment, and patient decision-making capacity and wishes.[24] The CGA also includes assessment of functional status, socioeconomic issues, psychosocial distress, cognitive function, nutrition, and medication-polypharmacy review.

Some important questions to consider when an older person is diagnosed with cancer include the following: Will the treatment provide more benefits than harm? Will he or she be able to tolerate the treatment safely? Is there need to optimize other co-morbidities or nutritional or functional status before starting treatment? What are the patient's preferences and wishes?

CANCER SURVIVORSHIP

It is estimated that there are currently more than 13.7 million cancer survivors in the United States, with breast cancer patients making up the largest portion of this group. Some of these individuals are cancer free, whereas others still have evidence of cancer and may be undergoing treatment.[1]

Over the past 20 years, the number of cancer survivors has increased threefold. With progressive advances in early detection and treatment, further increases in the number of cancer survivors are expected.[26]

The rapid increase in cancer survivors has been accompanied by a greater awareness of the long-term health and quality-of-life issues that a cancer diagnosis imposes. Cancer survivors experience a variety of long-term and late sequelae following treatment (discussed earlier in this chapter on pp. 265-271). The impact of cancer and its treatment confers greater risk of non-cancer-related death and co-morbidities (e.g., heart disease, diabetes, metabolic syndrome, endocrine dysfunction, osteoporosis) among cancer survivors. Furthermore, cancer survivors may continue to experience symptoms or functional impairment related to treatment for years after treatment.

The impact of a cancer diagnosis can affect many aspects of a patient's life, with cancer survivors commonly reporting financial, vocational, marital, and emotional concerns even long after treatment is over. These psychosocial effects can play a profound role in a patient's life after cancer, with issues related to living in uncertainty being frequently encountered.

To better assist cancer survivors, try to understand the meaning of the cancer experience from the individual's perspective.[27] Some patients may wish to return to their normal lives as soon as possible, and they might fail to attend scheduled follow-up appointments. Other survivors may become cancer advocates or active members of a cancer support group. Still others may allow their lives to revolve around the cancer and may even resist giving up the illness role. Some resources for survivors are listed in Table 16-20. Connecting diverse cancer survivors to culturally appropriate, evidence-based online support and resources is a strategy to enhance health outcomes.[28]

An important question that cancer survivors may ask is whether they should have children or whether their children will have genetic abnormalities. Recent and ongoing research suggests that children of cancer survivors are not at increased risk for genetic or congenital abnormalities. It is unknown whether humans have the ability to repair damage to germ cell DNA or whether processes such as infertility or miscarriages filter out any problems.[29]

TABLE 16-20 RESOURCES FOR CANCER SURVIVORS

Resource	Website

Resources for Cancer Survivors	*www.cancerinformation.com/survivorship/resources.aspx*

You can help cancer survivors by doing the following:

- Provide all cancer patients with a treatment summary and care plan outlining treatment exposures, risk of late effects, preventive care recommendations, and follow-up surveillance plan after completion of treatment. Care plans should clearly identify all members of the care team and their responsibilities for follow-up care. Also include referrals to appropriate supportive care and community resources that would benefit the patient in recovery or ongoing care.
- Coordinate care among the oncology team, primary health care provider, and other specialists. Teach health care providers about the needs of cancer survivors, including long-term effects of cancer and cancer treatments.
- Teach cancer survivors to look for and report any ongoing symptoms resulting from treatment, including late effects of radiation therapy and chemotherapy.
- Promote healthy behaviors:
  - *Prevention:* good nutrition, exercise, smoking avoidance, maintenance of proper weight, cardiac risk reduction, bone health
  - *Early detection:* routine health screenings (e.g., breast, colon), cholesterol, diabetes, osteoporosis screening as recommended
- Encourage cancer survivors to have regular follow-up examinations with an identified primary health care provider.
- Assess for psychoemotional, financial, health insurance, or vocational problems related to cancer. Assist patients in getting appropriate help if necessary.

CULTURALLY COMPETENT CARE

CANCER

Both cancer incidence and death rates are disproportionately higher in African Americans than in whites and other minority groups (see Cultural and Ethnic Health Disparities box). Although overall racial disparities in cancer death rates have been declining, death rates continue to be 33% higher among African American men and 16% higher among African American women than whites. In addition, African Americans are more likely to have later stage disease at the time of diagnosis than whites.[30,31]

Differences in survival rates from cancer are attributed primarily to a combination of factors, including poverty, difficult access to and poorer quality of health care, more co-morbid conditions, and differences in tumor biology. Disparities in cancer care exist throughout the continuum from cancer pre-

CULTURAL & ETHNIC HEALTH DISPARITIES

Cancer

- Cancer incidence and death rates for men are highest among African Americans, followed by whites, Hispanics, and Asians/Pacific Islanders.
- Cancer incidence rates for women are highest among whites, followed by African Americans, Hispanics, and Asians/Pacific Islanders.
- However, cancer death rates for women are highest among African Americans, followed by whites, Hispanics, and Asians/Pacific Islanders.

vention and screening to end-of-life care and survivorship. The disparity in prevention and screening results in cancer being in advanced stages at the time of diagnosis.[32]

Culturally competent care in oncology is needed to meet the needs of diverse groups. Culturally competent care involves awareness of personal background, how culture affects care delivery, and how to adapt to meet cultural needs. Nurses need to actively seek to understand cultural differences to meet the individualized needs. (Culturally competent care related to specific cancers is presented in the chapters where the cancer is discussed.)

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Trends in the incidence and death rates of cancer include the fact that
   a. lung cancer is the most common type of cancer in men.
   b. a higher percentage of women than men have lung cancer.
   c. breast cancer is the leading cause of cancer deaths in women.
   d. African Americans have a higher death rate from cancer than whites.
2. What features of cancer cells distinguish them from normal cells *(select all that apply)*?
   a. Cells lack contact inhibition.
   b. Cells return to a previous undifferentiated state.
   c. Oncogenes maintain normal cell expression.
   d. Proliferation occurs when there is a need for more cells.
   e. New proteins characteristic of embryonic stage emerge on cell membrane.
3. A characteristic of the stage of progression in the development of cancer is
   a. oncogenic viral transformation of target cells.
   b. a reversible steady growth facilitated by carcinogens.
   c. a period of latency before clinical detection of cancer.
   d. proliferation of cancer cells in spite of host control mechanisms.
4. The primary protective role of the immune system related to malignant cells is
   a. surveillance for cells with tumor-associated antigens.
   b. binding with free antigen released by malignant cells.
   c. production of blocking factors that immobilize cancer cells.
   d. responding to a new set of antigenic determinants on cancer cells.
5. The primary difference between benign and malignant neoplasms is the
   a. rate of cell proliferation.
   b. site of malignant tumor.
   c. requirements for cell nutrients.
   d. characteristic of tissue invasiveness.
6. The nurse is caring for a 59-year-old woman who had surgery 1 day ago for removal of a suspected malignant abdominal mass. The patient is awaiting the pathology report. She is tearful and says that she is scared to die. The most effective nursing intervention at this point is to use this opportunity to
   a. motivate change in an unhealthy lifestyle.
   b. teach her about the seven warning signs of cancer.
   c. instruct her about healthy stress relief and coping practices.
   d. allow her to communicate about the meaning of this experience.
7. The goals of cancer treatment are based on the principle that
   a. surgery is the single most effective treatment for cancer.
   b. initial treatment is always directed toward cure of the cancer.
   c. a combination of treatment modalities is effective for controlling many cancers.
   d. although cancer cure is rare, quality of life can be increased with treatment modalities.
8. The most effective method of administering a chemotherapy agent that is a vesicant is to
   a. give it orally.
   b. give it intraarterially.
   c. use an Ommaya reservoir.
   d. use a central venous access device.
9. The nurse explains to a patient undergoing brachytherapy of the cervix that she
   a. must undergo simulation to locate the treatment area.
   b. requires the use of radioactive precautions during nursing care.
   c. may experience desquamation of the skin on the abdomen and upper legs.
   d. requires shielding of the ovaries during treatment to prevent ovarian damage.
10. A patient on chemotherapy and radiation for head and neck cancer has a WBC count of $1.9 \times 10^3/\mu L$, hemoglobin of 10.8 g/dL, and a platelet count of $99 \times 10^3/\mu L$. Based on the CBC results, what is the most serious clinical finding?
    a. Cough, rhinitis, and sore throat
    b. Fatigue, nausea, and skin redness at site of radiation
    c. Temperature of 101.9° F, fatigue, and shortness of breath
    d. Skin redness at site of radiation, headache, and constipation
11. To prevent fever and shivering during an infusion of rituximab (Rituxan), the nurse should premedicate the patient with
    a. aspirin.
    b. acetaminophen.
    c. sodium bicarbonate.
    d. meperidine (Demerol).
12. The nurse counsels the patient receiving radiation therapy or chemotherapy that
    a. effective birth control methods should be used for the rest of the patient's life.
    b. if nausea and vomiting occur during treatment, the treatment plan will be modified.
    c. after successful treatment, a return to the person's previous functional level can be expected.
    d. the cycle of fatigue-depression-fatigue that may occur during treatment can be reduced by restricting activity.

13. A patient on chemotherapy for 10 weeks started at a weight of 121 lb. She now weighs 118 lb and has no sense of taste. Which nursing intervention would be a priority?
    - **a.** Advise the patient to eat foods that are fatty, fried, or high in calories.
    - **b.** Discuss with the physician the need for parenteral or enteral feedings.
    - **c.** Advise the patient to drink a nutritional supplement beverage at least three times a day.
    - **d.** Advise the patient to experiment with spices and seasonings to enhance the flavor of food.
14. A 70-year-old male patient has multiple myeloma. His wife calls to report that he sleeps most of the day, is confused when awake, and complains of nausea and constipation. Which complication of cancer is this most likely caused by?
    - **a.** Hypercalcemia
    - **b.** Tumor lysis syndrome
    - **c.** Spinal cord compression
    - **d.** Superior vena cava syndrome
15. A patient has recently been diagnosed with early stages of breast cancer. What is most appropriate for the nurse to focus on?
    - **a.** Maintaining the patient's hope
    - **b.** Preparing a will and advance directives
    - **c.** Discussing replacement child care for the patient's children
    - **d.** Discussing the patient's past experiences with her grandmother's cancer

1. d, 2. a, b, e, 3. d, 4. a, 5. d, 6. d, 7. c, 8. d, 9. b, 10. c, 11. b, 12. c, 13. d, 14. a, 15. a

- Content Updates

LEARNING OUTCOMES

1. Describe the composition of the major body fluid compartments.
2. Define processes involved in the regulation of movement of water and electrolytes between the body fluid compartments.
3. Describe the etiology, laboratory diagnostic findings, clinical manifestations, and nursing and collaborative management of the following disorders:
   a. Extracellular fluid volume imbalances: fluid volume deficit and fluid volume excess
   b. Sodium imbalances: hypernatremia and hyponatremia
   c. Potassium imbalances: hyperkalemia and hypokalemia
   d. Magnesium imbalances: hypermagnesemia and hypomagnesemia
   e. Calcium imbalances: hypercalcemia and hypocalcemia
   f. Phosphate imbalances: hyperphosphatemia and hypophosphatemia
4. Identify the processes to maintain acid-base balance.
5. Discuss the etiology, laboratory diagnostic findings, clinical manifestations, and nursing and collaborative management of the following acid-base imbalances: metabolic acidosis, metabolic alkalosis, respiratory acidosis, and respiratory alkalosis.
6. Describe the composition and indications of common IV fluid solutions.
7. Discuss the types and nursing management of commonly used central venous access devices.

HOMEOSTASIS

Body fluids and electrolytes play an important role in maintaining *homeostasis,* the stable internal environment of the body.[1] Body fluids are in constant motion transporting nutrients, electrolytes, and oxygen to cells and carrying waste products away from cells. The body uses a number of adaptive responses associated with these activities to keep the composition and volume of body fluids and electrolytes within the narrow limits of normal to maintain homeostasis and promote health.

Many diseases and their treatments can affect fluid and electrolyte balance. For example, a patient with metastatic breast or lung cancer may develop hypercalcemia because of bone destruction from tumor invasion. Chemotherapy prescribed to treat the cancer may result in nausea and vomiting and, subsequently, dehydration and acid-base imbalances. When correcting dehydration with IV fluids, the patient requires close monitoring to prevent fluid overload.

It is important for you to anticipate the potential for alterations in fluid and electrolyte balance associated with certain disorders and medical therapies, recognize the signs and symptoms of imbalances, and intervene with the appropriate action. This chapter describes the (1) normal control of fluids, electrolytes, and acid-base balance; (2) conditions that disrupt homeostasis and resultant manifestations; and (3) actions that

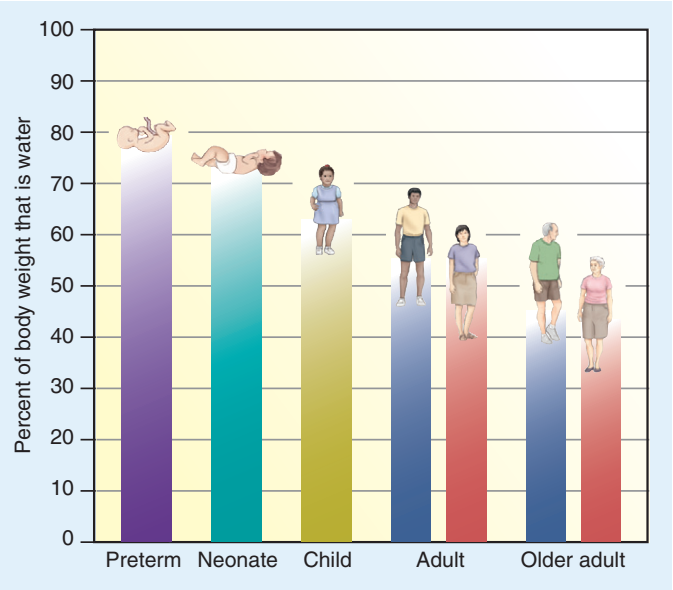

FIG. 17-1 Body water over the life span.

the health care provider and you can take to prevent fluid, electrolyte, and acid-base imbalances and restore homeostasis.

WATER CONTENT OF THE BODY

Water is the primary component of the body, accounting for approximately 50% to 60% of body weight in the adult. The water content varies with gender, body mass, and age (Fig. 17-1). The percentage of body weight that is composed of water is generally greater in men than in women because men tend to have more lean body mass. The more fat present in the body, the less the total water content. Therefore obese individuals have a lower percentage of body water than slender people do. Older adults, with less muscle mass and more fat content, have less body water for this same reason. In the older adult, body water content averages 45% to 55% of body weight, leaving them at a higher risk for fluid-related problems than young adults.

Body Fluid Compartments

The two fluid compartments in the body are the *intracellular space* (inside the cells) and the *extracellular space* (outside the cells) (Fig. 17-2). Approximately two thirds of the body water is located within cells and is termed *intracellular fluid* (ICF); ICF constitutes approximately 40% of body weight of an adult. The body of a 70-kg young man would contain approximately 42 L of water, of which 28 L would be located within cells.

The extracellular fluid (ECF) consists of *interstitial fluid* (the fluid in the spaces between cells), *plasma* (the liquid part of blood), and *transcellular fluid* (a very small amount of fluid contained within specialized cavities of the body). Transcellular fluids include cerebrospinal fluid; fluid in the gastrointestinal (GI) tract; and pleural, synovial, peritoneal, intraocular, and pericardial fluid. ECF consists of one third of the body water; this would amount to about 14 L in a 70-kg man. About 20% of ECF is in the intravascular space as plasma (3 L in a 70-kg man), and 70% is in the interstitial space (10 L in a 70-kg man). The fluid in the transcellular spaces totals about 1 L at any given time. However, because 3 to 6 L of fluid is secreted into and reabsorbed from the GI tract every day, loss of this fluid from

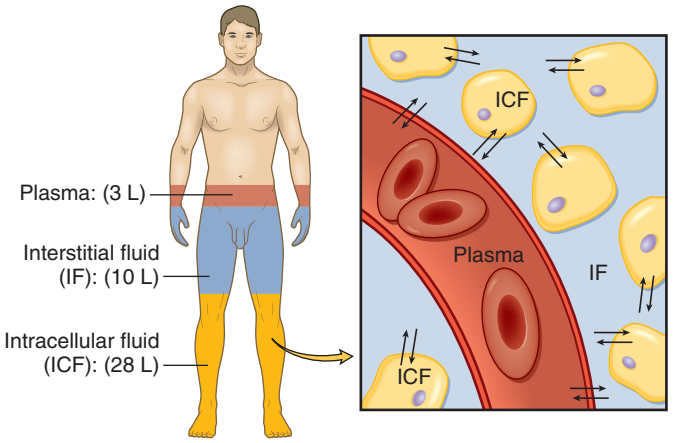

FIG. 17-2 Relative volumes of three body fluids. Values represent fluid distribution in a young male adult.

vomiting or diarrhea can produce serious fluid and electrolyte imbalances.

Calculation of Fluid Gain or Loss

One liter of water weighs 2.2 lb (1 kg). Body weight change, especially sudden change, is an excellent indicator of overall fluid volume loss or gain. For example, if a patient drinks 240 mL (8 oz) of fluid, weight gain will be 0.5 lb (0.23 kg). A patient receiving diuretic therapy who loses 4.4 lb (2 kg) in 24 hours has experienced a fluid loss of approximately 2 L. An adult patient who is fasting might lose approximately 1 to 2 lb/day. A weight loss exceeding this is likely due to loss of body fluid.

ELECTROLYTES

Electrolytes are substances whose molecules dissociate, or split into ions, when placed in water. *Ions* are electrically charged particles. **Cations** are positively charged ions. Examples include sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+}) ions. **Anions** are negatively charged ions. Examples include bicarbonate (HCO_3^-), chloride (Cl^-), and phosphate (PO_4^{3-}) ions. Most proteins bear a negative charge and are thus anions.

Measurement of Electrolytes

The milliequivalent (mEq) is the commonly used unit of measure for electrolytes. Electrolytes in body fluids are active chemicals that unite in varying combinations, so it is more practical to express their concentration as a measure of chemical activity (or milliequivalents) rather than as a measure of weight. Ions combine milliequivalent for milliequivalent. For example, 1 mEq (1 mmol) of sodium combines with 1 mEq (1 mmol) of chloride.

Electrolyte Composition of Fluid Compartments

Electrolyte composition varies between ECF and ICF. The overall concentration of electrolytes is approximately the same in the two compartments. However, concentrations of specific ions differ greatly (Fig. 17-3). In ECF the main cation is sodium, with small amounts of potassium, calcium, and magnesium. The primary ECF anion is chloride, with small amounts of bicarbonate, sulfate, and phosphate anions. In ICF the most

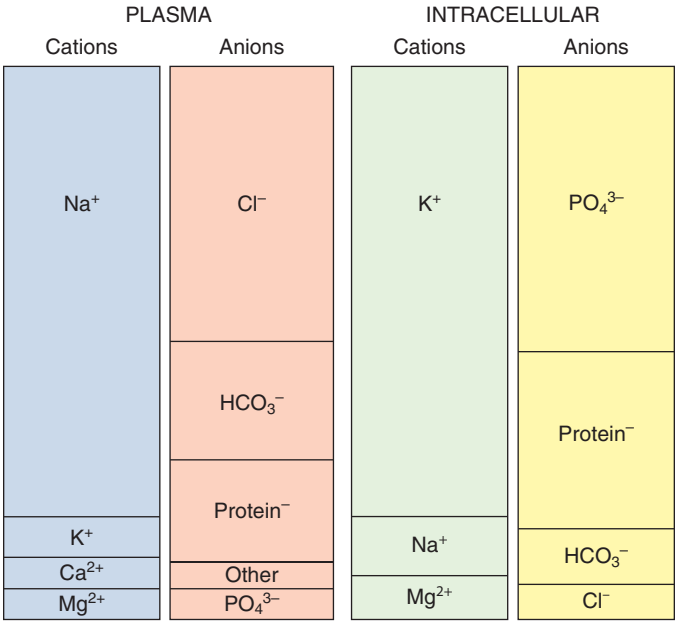

FIG. 17-3 The relative concentrations of the major cations and anions in the intracellular space and the plasma.

TABLE 17-1 NORMAL SERUM ELECTROLYTE VALUES

Electrolyte	Reference Interval
Anions	
Bicarbonate (HCO_3^-)	22-26 mEq/L (22-26 mmol/L)
Chloride (Cl^-)	96-106 mEq/L (96-106 mmol/L)
Phosphate (PO_4^{3-})*	2.4-4.4 mg/dL (0.78-1.42 mmol/L)
Cations	
Potassium (K^+)	3.5-5.0 mEq/L (3.5-5.0 mmol/L)
Magnesium (Mg^{2+})	1.5-2.5 mEq/L (0.75-1.25 mmol/L)
Sodium (Na^+)	135-145 mEq/L (135-145 mmol/L)
Calcium (Ca^{2+}) (total)	8.6-10.2 mg/dL (2.15-2.55 mmol/L)
Calcium (ionized)	4.6-5.3 mg/dL (1.16-1.32 mmol/L)

*The majority of the phosphorus (P) in the body is found as phosphate (PO_4^{3-}). The terms are used interchangeably in this text.

prevalent cation is potassium, with small amounts of magnesium and sodium. The prevalent ICF anion is phosphate, with some protein and a small amount of bicarbonate. (Normal serum electrolyte values are presented in Table 17-1.)

MECHANISMS CONTROLLING FLUID AND ELECTROLYTE MOVEMENT

The movement of electrolytes and water between ICF and ECF involves many different processes, including simple diffusion, facilitated diffusion, and active transport. Water moves as driven by two forces: hydrostatic pressure and osmotic pressure.

Diffusion

Diffusion is the movement of molecules from an area of high concentration to one of low concentration (Fig. 17-4). It occurs in liquids, gases, and solids. Net movement of molecules across a membrane stops when the concentrations are equal in both areas. The membrane separating the two areas must be permeable to the diffusing substance for the process to occur. Simple diffusion requires no external energy.

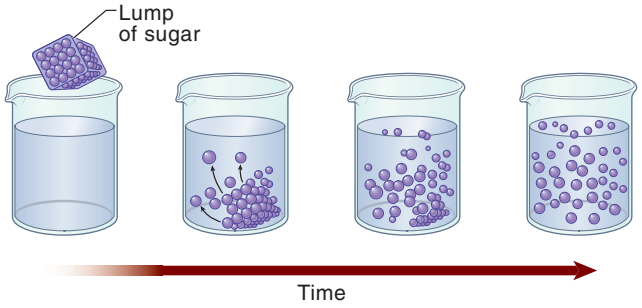

FIG. 17-4 Diffusion is the movement of molecules from an area of high concentration to an area of low concentration. Eventually the sugar molecules are evenly distributed.

Facilitated Diffusion

Facilitated diffusion involves the use of a protein carrier in the cell membrane. The protein carrier combines with a molecule, especially one too large to pass easily through the cell membrane, and assists in moving the molecule across the membrane from an area of high concentration to one of low concentration. Like simple diffusion, facilitated diffusion is passive and requires no energy. Glucose transport into the cell is an example of facilitated diffusion. The large glucose molecule must combine with a carrier molecule to be able to cross the cell membrane and enter most cells.

Active Transport

Active transport is a process in which molecules move against the concentration gradient. External energy is required for this process. An example is the sodium-potassium pump. The concentrations of sodium and potassium differ greatly intracellularly and extracellularly (see Fig. 17-3). To maintain this concentration difference, the cell uses active transport to move sodium out of the cell and potassium into the cell (Fig. 17-5). The energy source for this mechanism is adenosine triphosphate (ATP), produced in the cell's mitochondria.

Osmosis

Osmosis is the movement of water "down" a concentration gradient, that is, from a region of low solute concentration to one of high solute concentration, across a semipermeable membrane.[2] Imagine a chamber with two compartments separated by a semipermeable membrane, one that allows only the movement of water (Fig. 17-6). Water will move from the less concentrated side (has more water) to the more concentrated side of the chamber water (has less water). Osmosis requires no outside energy sources and stops when the concentration differences disappear or when hydrostatic pressure builds and is sufficient to oppose any further movement of water.

Whenever dissolved substances are contained in a space with a semipermeable membrane, they can pull water into the space by osmosis. The concentration of the solution determines the strength of the osmotic pull. The higher the concentration, the greater the solution's pulling, or **osmotic pressure.** Osmotic pressure is measured in milliosmoles (mOsm) and may be expressed as either fluid osmolarity or fluid osmolality. Although the terms *osmolarity* and *osmolality* are often used interchangeably, they are different measurements. *Osmolarity* measures the

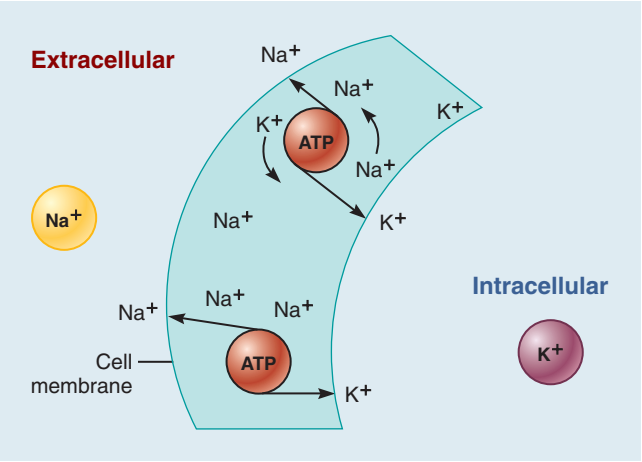

FIG. 17-5 Sodium-potassium pump. As sodium *(Na^+)* diffuses into the cell and potassium *(K^+)* diffuses out of the cell, an active transport system supplied with energy delivers Na^+ back to the extracellular compartment and K^+ to the intracellular compartment. *ATP,* Adenosine triphosphate.

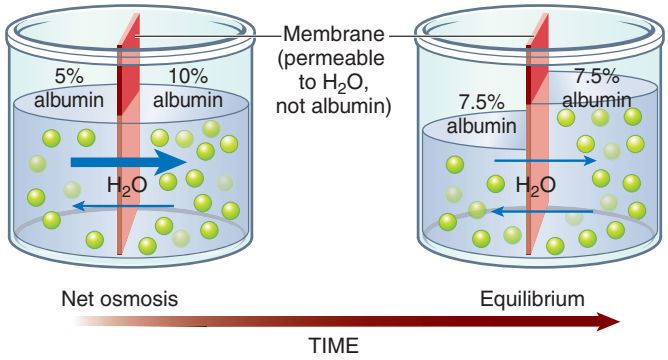

FIG. 17-6 Osmosis is the process of water movement through a semipermeable membrane from an area of low solute concentration to an area of high solute concentration.

total milliosmoles per liter of solution, or the concentration of molecules per volume of solution (mOsm/L). **Osmolality** measures the number of milliosmoles per kilogram of water, or the concentration of molecules per weight of water. Osmolality is the test typically performed to evaluate the concentration of plasma and urine.[2]

Measurement of Osmolality. Osmolality is approximately the same in the various body fluid spaces. Determining osmolality is important because it indicates the body's water balance. To assess the state of the body's water balance, one can measure or estimate plasma osmolality. Normal plasma osmolality is between 275 and 295 mOsm/kg. A value greater than 295 mOsm/kg indicates that the concentration of particles is too great or that the water content is too little. This condition is termed *water deficit.* A value less than 275 mOsm/kg indicates too little solute for the amount of water or too much water for the amount of solute. This condition is termed *water excess.* Both conditions are clinically significant. Because the major determinants of plasma osmolality are sodium and glucose, one can calculate the effective plasma osmolality based on the concentrations of those substances.

Osmolality of urine can range from 100 to 1300 mOsm/kg, depending on fluid intake and the amount of antidiuretic hormone (ADH) in circulation and the renal response to it.

Osmotic Movement of Fluids. The osmolality or tonicity of the fluid surrounding the cells affects them. Fluids with the same osmolality as the cell interior are termed **isotonic.** Normally, ECF and ICF are isotonic to one another, so no net movement of water occurs.

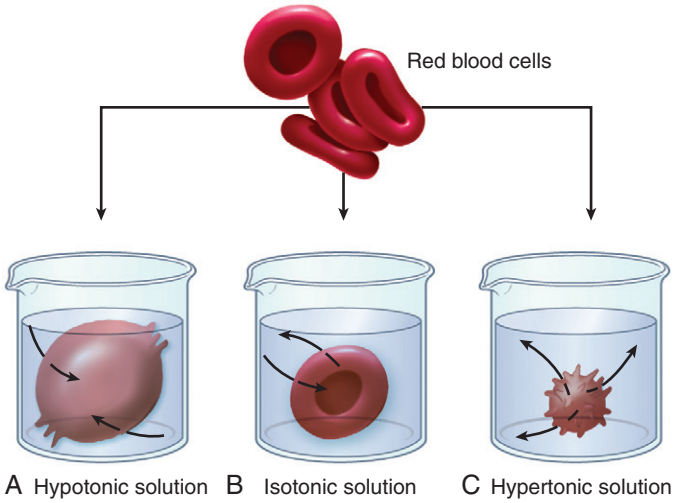

FIG. 17-7 Effects of water status on red blood cells. **A,** Hypotonic solution (H_2O excess) results in cellular swelling. **B,** Isotonic solution (normal H_2O balance) results in no change. **C,** Hypertonic solution (H_2O deficit) results in cellular shrinking.

Changes in the osmolality of ECF alter the volume of cells. Solutions in which the solutes are less concentrated than in the cells are termed **hypotonic** (hypoosmolar). If a cell is surrounded by hypotonic fluid, water moves into the cell, causing it to swell and possibly to burst. Fluids with solutes more concentrated than in cells, or an increased osmolality, are termed **hypertonic** (hyperosmolar). If hypertonic fluid surrounds a cell, water leaves the cell to dilute ECF; the cell shrinks and may eventually die (Fig. 17-7).

Hydrostatic Pressure

Hydrostatic pressure is the force within a fluid compartment. In the blood vessels, hydrostatic pressure is the blood pressure generated by the contraction of the heart. Hydrostatic pressure in the vascular system gradually decreases as the blood moves through the arteries until it is about 30 mm Hg in the capillary bed. At the capillary level, hydrostatic pressure is the major force that pushes water out of the vascular system and into the interstitial space.

Oncotic Pressure

Oncotic pressure (colloidal osmotic pressure) is the osmotic pressure caused by plasma colloids in solution. The major colloid in the vascular system contributing to the total osmotic pressure is protein. Plasma has substantial amounts of protein, whereas the interstitial space has very little. The plasma protein molecules attract water, pulling fluid from the tissue space to the vascular space. Under normal conditions, plasma oncotic pressure is approximately 25 mm Hg. The small amount of protein found in the interstitial space exerts an oncotic pressure of approximately 1 mm Hg.

FLUID MOVEMENT IN CAPILLARIES

As plasma flows through the capillary bed, four factors determine if fluid moves out of the capillary and into the interstitial

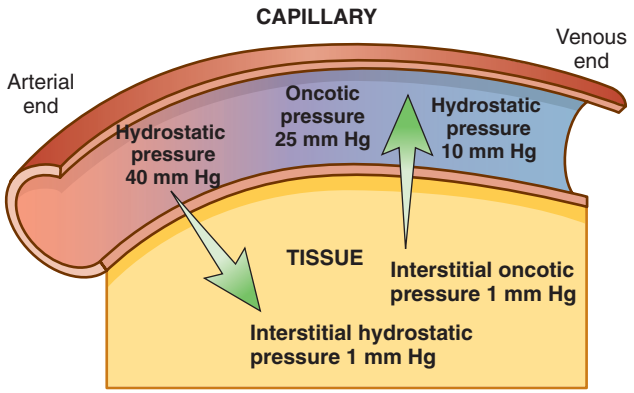

FIG. 17-8 Dynamics of fluid exchange between a capillary and tissue. An equilibrium exists between forces filtering fluid out of the capillary and forces absorbing fluid back into the capillary. Note that the hydrostatic pressure is greater at the arterial end of the capillary than at the venous end. The net effect of pressures at the arterial end of the capillary causes a movement of fluid into the tissue. At the venous end of the capillary, there is net movement of fluid back into the capillary.

space or if fluid moves back into the capillary from the interstitial space. The amount and direction of movement are determined by the interaction of (1) capillary hydrostatic pressure, (2) plasma oncotic pressure, (3) interstitial hydrostatic pressure, and (4) interstitial oncotic pressure.

Capillary hydrostatic pressure and interstitial oncotic pressure move water out of the capillaries. Plasma oncotic pressure and interstitial hydrostatic pressure move fluid into the capillaries. At the arterial end of the capillary, capillary hydrostatic pressure exceeds plasma oncotic pressure, and fluid moves into the interstitial space. At the venous end of the capillary, the capillary hydrostatic pressure is lower than plasma oncotic pressure, drawing fluid back into the capillary by the oncotic pressure created by plasma proteins (Fig. 17-8).

Fluid Shifts

If capillary or interstitial pressures change, fluid may abnormally shift from one compartment to another, resulting in edema or dehydration.

Shifts of Plasma to Interstitial Fluid. *Edema,* an accumulation of fluid in the interstitial space, occurs if venous hydrostatic pressure rises, plasma oncotic pressure decreases, or interstitial oncotic pressure rises. Edema may also develop if an obstruction of lymphatic outflow causes decreased removal of interstitial fluid.

Elevation of Venous Hydrostatic Pressure. Increasing the pressure at the venous end of the capillary inhibits fluid movement back into the capillary, which results in edema. Causes of increased venous pressure include fluid overload, heart failure, liver failure, obstruction of venous return to the heart (e.g., tourniquets, restrictive clothing, venous thrombosis), and venous insufficiency (e.g., varicose veins).

Decrease in Plasma Oncotic Pressure. Fluid remains in the interstitial space if the plasma oncotic pressure is too low to draw fluid back into the capillary. Low plasma protein content decreases oncotic pressure. This can result from excessive protein loss (renal disorders), deficient protein synthesis (liver disease), and deficient protein intake (malnutrition).

Elevation of Interstitial Oncotic Pressure. Trauma, burns, and inflammation can damage capillary walls and allow plasma proteins to accumulate in the interstitial space. This increases interstitial oncotic pressure, draws fluid into the interstitial space, and holds it there.

Shifts of Interstitial Fluid to Plasma. An increase in the plasma osmotic or oncotic pressure draws fluid into the plasma from the interstitial space. This could happen with administration of colloids, dextran, mannitol, or hypertonic solutions. Increasing the tissue hydrostatic pressure is another way of causing a shift of fluid into plasma. Wearing elastic compression gradient stockings or hose to decrease peripheral edema is a therapeutic application of this effect.

FLUID SPACING

Fluid spacing is a term used to describe the distribution of body water. *First spacing* describes the normal distribution of fluid in ICF and ECF compartments. *Second spacing* refers to an abnormal accumulation of interstitial fluid (i.e., edema). *Third spacing* occurs when fluid accumulates in a portion of the body from which it is not easily exchanged with the rest of the ECF. Third-spaced fluid is trapped and unavailable for functional use. Examples of third spacing are ascites; sequestration of fluid in the abdominal cavity with peritonitis; and edema associated with burns, trauma, or sepsis.[3]

REGULATION OF WATER BALANCE

Hypothalamic-Pituitary Regulation

Water balance is maintained via the finely tuned balance of water intake and excretion. Water ingestion will equal water loss in the individual who has free access to water, a normal thirst and ADH mechanism, and normally functioning kidneys.

An intact thirst mechanism is critical because it is the primary protection against the development of hyperosmolality. Osmoreceptors in the hypothalamus sense a body fluid deficit or increase in plasma osmolality, which in turn stimulates thirst and ADH release. Thirst causes the patient to drink water. The distal tubules and collecting ducts in the kidneys respond to ADH by becoming more permeable to water. The result is increased water reabsorption from the tubular filtrate into the blood and decreased excretion in the urine. Together these factors result in increased free water in the body and decreased plasma osmolality.

The patient who cannot recognize or act on the sensation of thirst is at risk for fluid deficit and hyperosmolality. Other factors that stimulate ADH release include stress, nausea, nicotine, and morphine. A decreased plasma osmolality or water excess suppresses secretion of ADH, resulting in urinary excretion of water. It is common for the postoperative patient to have a lower plasma osmolality, possibly because of the stress of surgery and opioid analgesia. Social and psychologic factors not related to fluid balance also affect the desire to consume fluids. A dry mouth will cause the patient to drink, even when there is no measurable body water deficit.

Renal Regulation

The kidneys are the primary organs for regulating fluid and electrolyte balance (see Chapter 45). The kidneys regulate water balance by adjusting urine volume and the urinary excretion of most electrolytes to maintain a balance between overall intake and output. The kidneys filter the total plasma volume many times each day. In the average adult the kidneys reabsorb 99% of this filtrate, producing approximately 1.5 L of urine per day.

As the filtrate moves through the renal tubules, selective reabsorption of water and electrolytes and secretion of electrolytes result in the production of urine that is greatly different in composition and concentration from plasma. This process helps maintain normal plasma osmolality, electrolyte balance, blood volume, and acid-base balance. The renal tubules are the site for the actions of ADH and aldosterone.

With severely impaired renal function, the kidneys cannot maintain fluid and electrolyte balance. This condition results in edema, potassium and phosphorus retention, acidosis, and other electrolyte imbalances (see Chapter 47).

Adrenal Cortical Regulation

Glucocorticoids and mineralocorticoids secreted by the adrenal cortex help regulate both water and electrolytes. The glucocorticoids (e.g., cortisol) primarily have an antiinflammatory effect and increase serum glucose levels, whereas the mineralocorticoids (e.g., aldosterone) enhance sodium retention and potassium excretion (Fig. 17-9). When sodium is reabsorbed, water follows because of osmotic changes.

Cortisol is the most abundant glucocorticoid. In large doses, cortisol has both glucocorticoid (glucose elevating and antiinflammatory) and mineralocorticoid (sodium-retention) effects. Normally cortisol secretion is in a diurnal or circadian pattern. Increased cortisol secretion occurs in response to physical and psychologic stress, affecting many body functions, including fluid and electrolyte balance (Fig. 17-10).

Aldosterone is a mineralocorticoid with potent sodium-retaining and potassium-excreting capabilities. Decreased renal perfusion or decreased sodium delivery to the distal portion of the renal tubule activates the renin-angiotensin-aldosterone system (RAAS), which results in aldosterone secretion (see Fig. 45-4). In addition to the RAAS, increased plasma potassium, decreased plasma sodium, and adrenocorticotropic hormone (ACTH) from the anterior pituitary act directly on the adrenal cortex to stimulate the secretion of aldosterone (see Fig. 17-9).

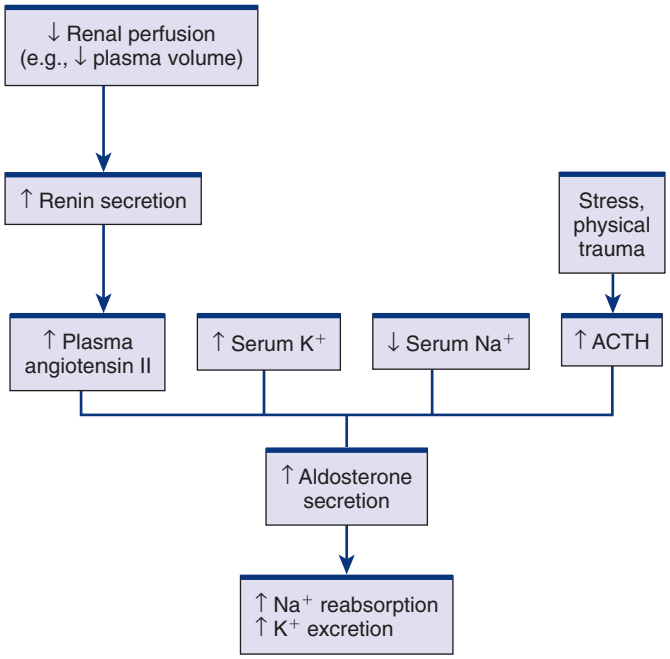

FIG. 17-9 Factors affecting aldosterone secretion. *ACTH,* Adrenocorticotropic hormone.

Cardiac Regulation

Natriuretic peptides, including atrial natriuretic peptide (ANP) and b-type natriuretic peptide (BNP), are hormones produced by cardiomyocytes. They are natural antagonists to the RAAS. They are produced in response to increased atrial pressure (increased volume, such as occurs in heart failure) and high serum sodium levels. They suppress secretion of aldosterone, renin, and ADH, and the action of angiotensin II. In the renal tubules these peptides promote excretion of sodium and water, resulting in a decrease in blood volume and blood pressure.

Gastrointestinal Regulation

Daily water intake and output are normally between 2000 and 3000 mL (Table 17-2). Oral intake of fluids accounts for most

TABLE 17-2 NORMAL FLUID BALANCE IN THE ADULT

Intake	
Fluids	1200 mL
Solid food	1000 mL
Water from oxidation	300 mL
Total	2500 mL
Output	
Insensible loss (skin and lungs)	900 mL
In feces	100 mL
Urine	1500 mL
Total	2500 mL

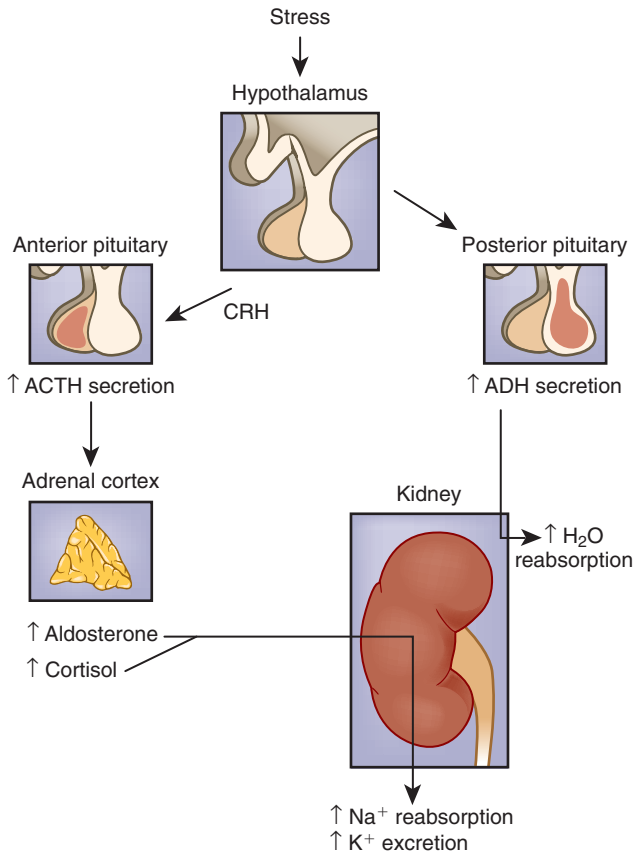

FIG. 17-10 Effects of stress on fluid and electrolyte balance. *ACTH,* Adrenocorticotropic hormone; *ADH,* antidiuretic hormone; *CRH,* corticotropin-releasing hormone.

of the water intake. Water intake also includes water from food metabolism and water present in solid foods. Lean meat is approximately 70% water, whereas the water content of many fruits and vegetables approaches 100%.

In addition to oral intake, the GI tract normally secretes approximately 8000 mL of digestive fluids each day. Most of this fluid is reabsorbed in the GI tract; only a small amount is normally eliminated in feces. Diarrhea and vomiting, which prevent GI reabsorption of this secreted fluid, can lead to significant fluid and electrolyte loss.

Insensible Water Loss

Insensible water loss, which is invisible vaporization from the lungs and skin, assists in regulating body temperature. Normally, about 600 to 900 mL/day is lost. Accelerated body metabolism, which occurs with increased body temperature and exercise, increases the amount of water loss.

Do not confuse water loss through the skin with the vaporization of water excreted by sweat glands. Insensible perspiration causes only water loss. Excessive sweating *(sensible perspiration)* caused by exercise, fever, or high environmental temperatures may lead to large losses of water and electrolytes.

GERONTOLOGIC CONSIDERATIONS

FLUID AND ELECTROLYTES

The older adult experiences normal physiologic changes with aging that increase susceptibility to fluid and electrolyte imbalances. Structural changes to the kidneys and a decrease in the renal blood flow lead to decreased glomerular filtration rate, decreased creatinine clearance, and loss of the ability to concentrate urine and conserve water. Hormonal changes include a decrease in renin and aldosterone and an increase in ADH and ANP.[4] Loss of subcutaneous tissue and thinning of the dermis lead to increased loss of moisture through the skin and an inability to respond to heat or cold quickly.

Older adults experience a decrease in the thirst mechanism, resulting in decreased fluid intake despite increases in osmolality and serum sodium level. Older adults, especially if they are ill, are at increased risk of free-water loss and subsequent development of hypernatremia secondary to impairment of the thirst mechanism and barriers to obtaining fluids to drink.[5]

Healthy older adults usually consume adequate fluids to remain well hydrated. However, functional changes may occur that affect the ability to independently obtain fluids. For example, musculoskeletal changes, such as stiffness of the hands and fingers, can lead to a decreased ability to hold a glass or cup. Mental status changes, such as confusion or disorientation, or changes in ambulation status may lead to a decreased ability to obtain fluids. To reduce incontinent episodes, the older adult may intentionally restrict fluid intake.

You should not automatically attribute older patients' fluid and electrolyte problems to the natural processes of aging. Adapt your assessment and nursing interventions to account for these physiologic and functional changes. Suggestions for alterations in nursing care for the older adult are presented throughout this chapter.

FLUID AND ELECTROLYTE IMBALANCES

Fluid and electrolyte imbalances occur to some degree in most patients with a major illness or injury because illness disrupts the normal homeostatic mechanism. Some fluid and electrolyte imbalances are directly caused by illness or disease (e.g., burns, heart failure). At other times, therapeutic measures (e.g., IV fluid replacement, diuretics) cause or contribute to fluid and electrolyte imbalances. Perioperative patients are at risk for the development of fluid and electrolyte imbalances because of fluid restrictions, blood or fluid loss, and the stress of surgery.[6]

Imbalances are commonly classified as *deficits* or *excesses.* Although each imbalance is discussed separately in this chapter, it is common for more than one imbalance to occur in the same patient. For example, a patient with prolonged nasogastric suction will lose sodium, potassium, hydrogen, and chloride ions. These imbalances may result in a deficiency of both sodium and potassium, a fluid volume deficit, and metabolic alkalosis caused by loss of hydrochloric acid.

EXTRACELLULAR FLUID VOLUME IMBALANCES

ECF volume deficit *(hypovolemia)* and ECF volume excess *(hypervolemia)* are common clinical conditions. ECF volume imbalances are typically accompanied by one or more electrolyte imbalances, particularly changes in the serum sodium level.

Fluid Volume Deficit

Fluid volume deficit can occur with abnormal loss of body fluids (e.g., diarrhea, fistula drainage, hemorrhage, polyuria), inadequate intake, or a shift of fluid from plasma into interstitial fluid. The term *fluid volume deficit* is not interchangeable with the term *dehydration. Dehydration* refers to loss of pure water alone without a corresponding loss of sodium. Causes and clinical manifestations of fluid volume deficit are listed in Table 17-3.

Collaborative Care

The goal of treatment for fluid volume deficit is to correct the underlying cause and to replace both water and any needed electrolytes. Balanced IV solutions, such as lactated Ringer's solution, are usually given. Isotonic (0.9%) sodium chloride is used when rapid volume replacement is indicated. Blood is administered when volume loss is due to blood loss.

Fluid Volume Excess

Fluid volume excess may result from excessive intake of fluids, abnormal retention of fluids (e.g., heart failure, renal failure), or a shift of fluid from interstitial fluid into plasma fluid. Although fluid shifts between the interstitial space and plasma do not alter the overall volume of ECF, these shifts result in changes in the intravascular volume. Causes and clinical manifestations of fluid volume excess are listed in Table 17-3.

Collaborative Care

The goal of treatment for fluid volume excess is removing fluid without producing abnormal changes in the electrolyte composition or osmolality of ECF. The primary cause must be identified and treated. Diuretics and fluid restriction are the primary forms of therapy. Restriction of sodium intake may also be indicated. If the fluid excess leads to ascites or pleural

TABLE 17-3 EXTRACELLULAR FLUID IMBALANCES: CAUSES AND CLINICAL MANIFESTATIONS

ECF Volume Deficit	ECF Volume Excess
Causes	
• ↑ Insensible water loss or perspiration (high fever, heatstroke) • Diabetes insipidus • Osmotic diuresis • Hemorrhage • GI losses: vomiting, NG suction, diarrhea, fistula drainage • Overuse of diuretics • Inadequate fluid intake • Third-space fluid shifts: burns, intestinal obstruction	• Excessive isotonic or hypotonic IV fluids • Heart failure • Renal failure • Primary polydipsia • SIADH • Cushing syndrome • Long-term use of corticosteroids
Clinical Manifestations	
• Restlessness, drowsiness, lethargy, confusion • Thirst, dry mucous membranes • Decreased skin turgor, ↓ capillary refill • Postural hypotension, ↑ pulse, ↓ CVP • ↓ Urine output, concentrated urine • ↑ Respiratory rate • Weakness, dizziness • Weight loss • Seizures, coma	• Headache, confusion, lethargy • Peripheral edema • Jugular venous distention • Bounding pulse, ↑ BP, ↑ CVP • Polyuria (with normal renal function) • Dyspnea, crackles, pulmonary edema • Muscle spasms • Weight gain • Seizures, coma

CVP, Central venous pressure; *ECF,* extracellular fluid; *SIADH,* syndrome of inappropriate antidiuretic hormone.

effusion, an abdominal paracentesis or thoracentesis may be necessary.

NURSING MANAGEMENT EXTRACELLULAR FLUID VOLUME IMBALANCES

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with fluid imbalances include, but are not limited to, the following:

ECF volume deficit:

- Deficient fluid volume *related to* excessive ECF losses or decreased fluid intake
- Decreased cardiac output *related to* excessive ECF losses or decreased fluid intake
- Risk for deficient fluid volume *related to* excessive ECF losses or decreased fluid intake
- Potential complication: hypovolemic shock

ECF volume excess:

- Excess fluid volume *related to* increased water and/or sodium retention
- Impaired gas exchange *related to* water retention leading to pulmonary edema
- Risk for impaired skin integrity *related to* edema
- Activity intolerance *related to* increased water retention, fatigue, and weakness
- Disturbed body image *related to* altered body appearance secondary to edema
- Potential complications: pulmonary edema, ascites

NURSING IMPLEMENTATION

INTAKE AND OUTPUT. The use of 24-hour intake and output records gives valuable information regarding fluid and electrolyte problems. An accurately recorded intake-and-output flow sheet can identify sources of excessive intake or fluid losses. Intake should include oral, IV, and tube feedings and retained irrigants. Output includes urine, excess perspiration, wound or tube drainage, vomitus, and diarrhea. Estimate fluid loss from wounds and perspiration. Measure the urine specific gravity according to agency policy. Readings of greater than 1.025 indicate concentrated urine, whereas those of less than 1.010 indicate dilute urine.

CARDIOVASCULAR CHANGES. Monitoring the patient for cardiovascular changes is necessary to prevent or detect complications from fluid and electrolyte imbalances. Signs and symptoms of ECF volume excess and deficit are reflected in changes in blood pressure, pulse force, and jugular venous distention. In fluid volume excess the pulse is full, bounding, and not easily obliterated. Increased volume causes distended neck veins (jugular venous distention) and increased blood pressure.

In mild to moderate fluid volume deficit, compensatory mechanisms include sympathetic nervous system stimulation of the heart and peripheral vasoconstriction. Stimulation of the heart increases the heart rate and, combined with vasoconstriction, maintains the blood pressure within normal limits. A change in position from lying to sitting or standing may elicit a further increase in the heart rate or a decrease in the blood pressure (orthostatic hypotension). If vasoconstriction and tachycardia provide inadequate compensation, hypotension occurs when the patient is recumbent. Severe fluid volume deficit can cause flattened neck veins and a weak, thready pulse that is easily obliterated. Severe, untreated fluid deficit will result in shock.

RESPIRATORY CHANGES. Both fluid excess and fluid deficit affect respiratory status. ECF excess can result in pulmonary congestion and pulmonary edema as increased hydrostatic pressure in the pulmonary vessels forces fluid into the alveoli. The patient will experience shortness of breath and moist crackles on auscultation. The patient with ECF deficit will demonstrate an increased respiratory rate because of decreased tissue perfusion and resultant hypoxia.

NEUROLOGIC CHANGES. Changes in neurologic function may occur with fluid volume excesses or deficits. ECF excess may result in cerebral edema from increased hydrostatic pressure in cerebral vessels. Alternatively, profound volume depletion may cause an alteration in sensorium secondary to reduced cerebral tissue perfusion.

Assessment of neurologic function includes evaluation of (1) the level of consciousness, which includes responses to verbal and painful stimuli and determination of a person's orientation to time, place, and person; (2) pupillary response to light and equality of pupil size; and (3) voluntary movement of the extremities, degree of muscle strength, and reflexes. Nursing care focuses on maintaining patient safety.

DAILY WEIGHTS. Accurate daily weights provide the easiest measurement of volume status. An increase of 1 kg (2.2 lb) is equal to 1000 mL (1 L) of fluid retention (provided the person has maintained usual dietary intake or has not been on nothing-by-mouth [NPO] status). Obtain the weight under standardized conditions, that is, weigh the patient at the same time every day, wearing the same garments, and on the same carefully calibrated scale. Remove excess bedding and empty all drainage

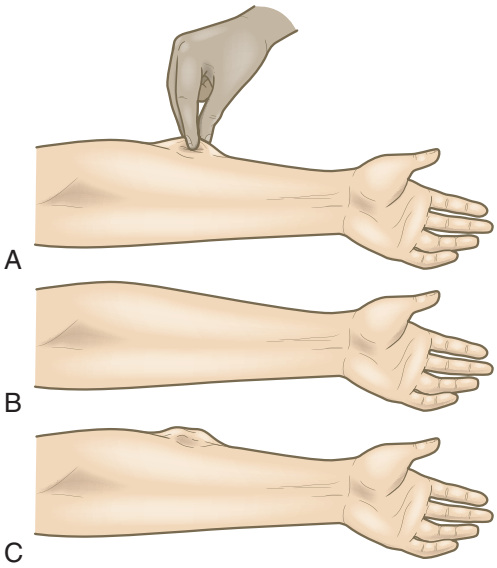

FIG. 17-11 Assessment of skin turgor. **A** and **B,** When normal skin is pinched, it resumes shape in seconds. **C,** If the skin remains wrinkled for 20 to 30 seconds, the patient has poor skin turgor.

bags before the weighing. If the patient has items present that are not there every day, such as bulky dressings or tubes, note this along with the weight.

SKIN ASSESSMENT AND CARE. Detect clues to ECF volume deficit and excess by inspecting the skin. Examine the skin for turgor and mobility. Normally a fold of skin, when pinched, will readily move and, on release, rapidly return to its former position. Skin areas over the sternum, abdomen, and anterior forearm are the usual sites for evaluation of tissue turgor (Fig. 17-11). In older people, decreased skin turgor is less predictive of fluid deficit because of the loss of tissue elasticity.[4] In ECF volume deficit, skin turgor is diminished, and there is a lag in the pinched skinfold's return to its original state (referred to as *tenting*).

The skin may be cool and moist if there is vasoconstriction to compensate for the decreased fluid volume. Mild hypovolemia usually does not stimulate this compensatory response. Consequently, the skin will be warm and dry. Volume deficit may also cause the skin to appear dry and wrinkled. These signs may be difficult to evaluate in the older adult because the patient's skin may be normally dry, wrinkled, and nonelastic. Oral mucous membranes will be dry, the tongue may be furrowed, and the individual often complains of thirst. Routine oral care is critical for the comfort of a patient who is dehydrated or fluid restricted for management of fluid volume excess.

Edematous skin may feel cool because of fluid accumulation and a decrease in blood flow secondary to the pressure of the fluid. The fluid can also stretch the skin, causing it to feel taut and hard. Assess edema by pressing with a thumb or forefinger over the edematous area. A grading scale is used to standardize the description if an indentation (ranging from 1+ [slight edema; 2-mm indentation] to 4+ [pitting edema; 8-mm indentation]) remains when pressure is released. Evaluate for edema in areas where soft tissues overlie a bone, with preferred sites being the tibia, fibula, and sacrum.

Good skin care for the person with ECF volume excess or deficit is important. Protect edematous tissues from extremes of heat and cold, prolonged pressure, and trauma. Frequent skin care and changes in position will prevent skin breakdown. Elevate edematous extremities to promote venous return and fluid reabsorption. Dehydrated skin needs frequent care without the use of soap. Applying moisturizing creams or oils increases moisture retention and stimulates circulation.

OTHER NURSING MEASURES. Carefully monitor the rates of infusion of IV fluid solutions. Be cautious about any attempts to "catch up," particularly when large volumes of fluid or certain electrolytes are involved. This is especially true in patients with cardiac, renal, or neurologic problems. Patients receiving tube feedings need supplementary water added to their enteral formula. The amount of additional water depends on the osmolarity of the feeding and the patient's condition.

Do not allow the patient with nasogastric suction to drink water because it will increase the loss of electrolytes. Occasionally the patient may be given small amounts of ice chips to suck. Irrigate nasogastric tubes with isotonic saline solution, not with water. Water causes diffusion of electrolytes into the gastric lumen from mucosal cells. The suction then removes the electrolytes, increasing the risk of electrolyte imbalances.

Nurses in hospitals and long-term care facilities should encourage and help the older or debilitated patient to maintain adequate oral intake. Assess the patient's ability to obtain adequate fluids independently, express thirst, and swallow effectively.[4] Fluids should be easily accessible. Assist older adults with physical limitations, such as arthritis, to open and hold containers. A variety of types of fluids should be available, and assess for individual preferences. Serve fluids at the temperature preferred by the patient. Seventy percent to 80% of the daily intake of fluids should be with meals, with fluid supplements between meals. Older adults may choose to decrease or eliminate fluids 2 hours before bedtime to decrease nocturia or incontinence. The unconscious or cognitively impaired patient is at increased risk because of an inability to express thirst and act on it. In these patients, accurately document fluid intake and losses and carefully evaluate the adequacy of intake and output.[4]

SODIUM IMBALANCES

Sodium, the main cation of ECF, plays a major role in maintaining the concentration and volume of ECF and influencing water distribution between ECF and ICF. Sodium plays an important role in the generation and transmission of nerve impulses, muscle contractility, and the regulation of acid-base balance.

Because sodium is the primary determinant of ECF osmolality, sodium imbalances are typically associated with parallel changes in osmolality. Serum sodium is measured in milliequivalents per liter (mEq/L) or millimoles per liter (mmol/L). The serum sodium level reflects the ratio of sodium to water, not necessarily the loss or gain of sodium. Changes in the serum sodium level may reflect a primary water imbalance, a primary sodium imbalance, or a combination of the two. Sodium imbalances are typically associated with imbalances in ECF volume (Figs. 17-12 and 17-13).

The GI tract absorbs sodium from foods. Typically, daily intake of sodium far exceeds the body's daily requirements. Sodium leaves the body through urine, sweat, and feces. The kidneys are the primary regulator of sodium balance. The kidneys regulate the ECF concentration of sodium by excreting or retaining water under the influence of ADH. Aldosterone

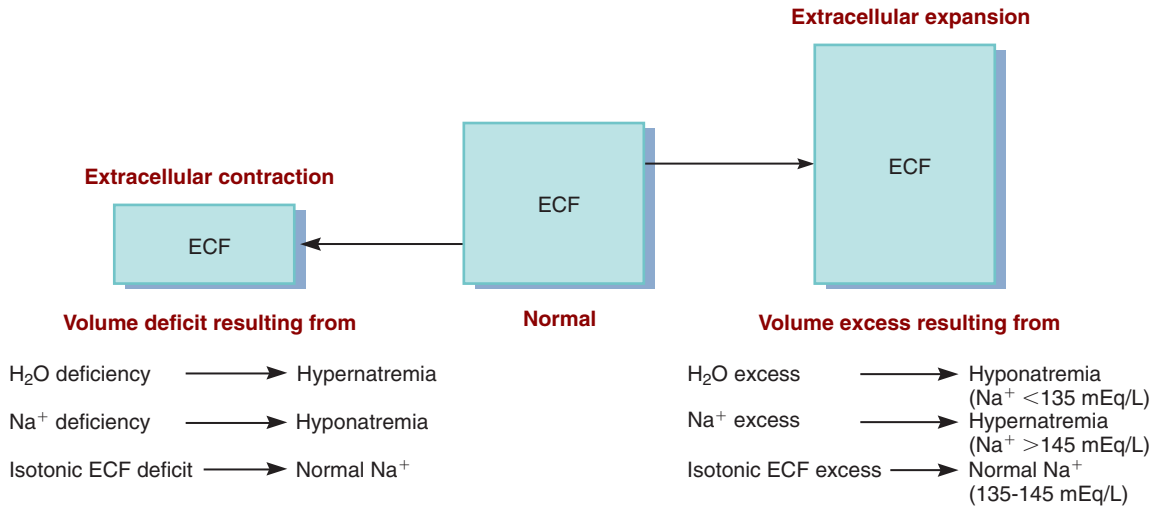

FIG. 17-12 Differential assessment of extracellular fluid *(ECF)* volume.

also plays a role in sodium regulation by promoting sodium reabsorption from the renal tubules.

Hypernatremia

Hypernatremia, an elevated serum sodium, may occur with water loss or sodium gain. Because sodium is the major determinant of the ECF osmolality, hypernatremia causes hyperosmolality. In turn, ECF hyperosmolality causes a shift of water out of the cells, which leads to cellular dehydration. As discussed earlier, the primary protection against the development of hyperosmolality is thirst. Hypernatremia is not a problem in an alert person who has access to water, can sense thirst, and is able to swallow. Hypernatremia secondary to water deficiency is often the result of an impaired level of consciousness or an inability to obtain fluids.

Several clinical states can produce hypernatremia from water loss (Table 17-4). A deficiency in the synthesis or release of ADH from the posterior pituitary gland (central diabetes insipidus) or a decrease in kidney responsiveness to ADH (nephrogenic diabetes insipidus) can result in profound diuresis, thus producing a water deficit and hypernatremia. Hyperosmolality with osmotic diuresis can result from administration of concentrated hyperosmolar tube feedings and hyperglycemia associated with uncontrolled diabetes mellitus. Other causes of hypernatremia include excessive sweating and increased sensible losses from high fever.

Excessive sodium intake with inadequate water intake can also lead to hypernatremia. Examples of sodium gain include IV administration of hypertonic saline or sodium bicarbonate, use of sodium-containing drugs, excessive oral intake of sodium (e.g., ingestion of seawater), and *primary aldosteronism* (hypersecretion of aldosterone) caused by a tumor of the adrenal glands.

Clinical Manifestations. The manifestations of hypernatremia are primarily the result of water shifting out of cells into ECF with resultant dehydration and shrinkage of cells (see Table 17-4). Dehydration of brain cells results in neurologic manifestations such as intense thirst, agitation, and decreased alertness, ranging from sleepiness to coma.[7] If there is any accompanying

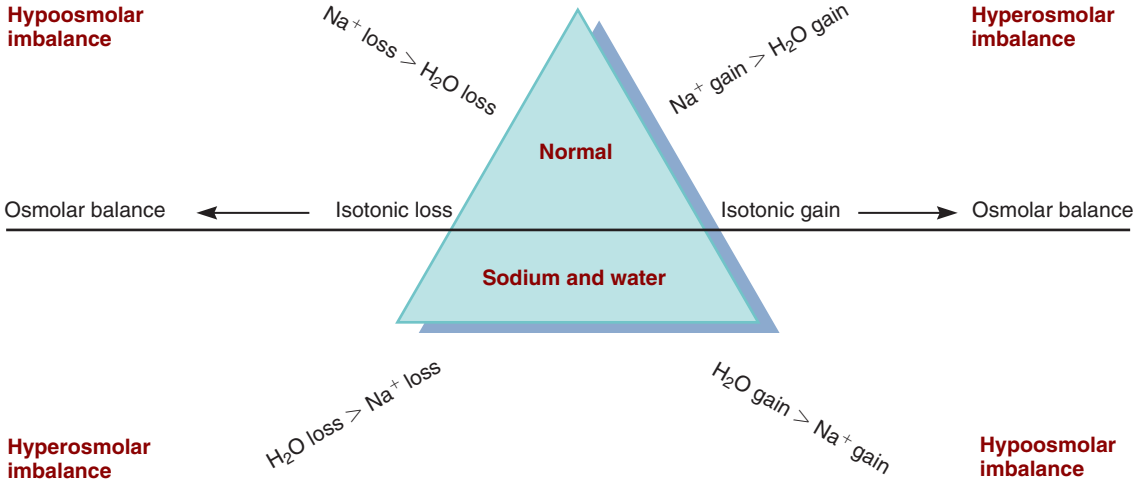

FIG. 17-13 Isotonic gains and losses affect mainly the extracellular fluid (ECF) compartment with little or no water movement into the cells. Hypertonic imbalances cause water to move from inside the cell into ECF to dilute the concentrated sodium, causing cell shrinkage. Hypotonic imbalances cause water to move into the cell, causing cell swelling.

TABLE 17-4 SODIUM IMBALANCES: CAUSES AND CLINICAL MANIFESTATIONS

Hypernatremia (Na^+ >145 mEq/L [mmol/L])	Hyponatremia (Na^+ <135 mEq/L [mmol/L])
Causes	
Excessive Sodium Intake	***Excessive Sodium Loss***
• IV fluids: hypertonic NaCl, excessive isotonic NaCl, IV sodium bicarbonate • Hypertonic tube feedings without water supplements • Near-drowning in salt water	• *GI losses:* diarrhea, vomiting, fistulas, NG suction • *Renal losses:* diuretics, adrenal insufficiency, Na^+ wasting renal disease • *Skin losses:* burns, wound drainage
Inadequate Water Intake	***Inadequate Sodium Intake***
• Unconscious or cognitively impaired individuals	• Fasting diets
Excessive Water Loss (↑ sodium concentration)	***Excessive Water Gain (↓ sodium concentration)***
• ↑ Insensible water loss (high fever, heatstroke, prolonged hyperventilation) • Osmotic diuretic therapy • Diarrhea	• Excessive hypotonic IV fluids • Primary polydipsia
Disease States	***Disease States***
• Diabetes insipidus • Primary hyperaldosteronism • Cushing syndrome • Uncontrolled diabetes mellitus	• SIADH • Heart failure • Primary hypoaldosteronism
Clinical Manifestations	
Hypernatremia With Decreased ECF Volume	***Hyponatremia With Decreased ECF Volume***
• Restlessness, agitation, twitching, seizures, coma • Intense thirst. Dry, swollen tongue. Sticky mucous membranes • Postural hypotension, ↓ CVP, weight loss, ↑ pulse • Weakness, lethargy	• Irritability, apprehension, confusion, dizziness, personality changes, tremors, seizures, coma • Dry mucous membranes • Postural hypotension, ↓ CVP, ↓ jugular venous filling, ↑ pulse, thready pulse • Cold and clammy skin
Hypernatremia With Normal or Increased ECF Volume	***Hyponatremia With Normal or Increased ECF Volume***
• Restlessness, agitation, twitching, seizures, coma • Intense thirst, flushed skin • Weight gain, peripheral and pulmonary edema, ↑ BP, ↑ CVP	• Headache, apathy, confusion, muscle spasms, seizures, coma • Nausea, vomiting, diarrhea, abdominal cramps • Weight gain, ↑ BP, ↑ CVP

CVP, Central venous pressure; *ECF,* extracellular fluid; *SIADH,* syndrome of inappropriate antidiuretic hormone.

ECF volume deficit, manifestations such as postural hypotension, weakness, and decreased skin turgor occur.

NURSING AND COLLABORATIVE MANAGEMENT HYPERNATREMIA

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with hypernatremia include, but are not limited to, the following:

- Risk for injury *related to* altered sensorium and seizures
- Risk for fluid volume deficit *related to* excessive intake of sodium and/or loss of water
- Risk for electrolyte imbalance *related to* excessive intake of sodium and/or loss of water
- Potential complication: seizures and coma leading to irreversible brain damage

NURSING IMPLEMENTATION

The primary goal of treatment of hypernatremia is to treat the underlying cause. In primary water deficit, fluid replacement is provided either orally or IV with isotonic or hypotonic fluids such as 5% dextrose in water or 0.45% sodium chloride saline solution.[8] The goal of treatment for sodium excess is to dilute the sodium concentration with sodium-free IV fluids, such as 5% dextrose in water, and to promote excretion of the excess sodium by administering diuretics. (See Chapter 50 for specific treatment of diabetes insipidus.)

Monitor serum sodium levels and the patient's response to therapy. Quickly reducing serum sodium levels can cause a rapid shift of water back into the cells, resulting in cerebral edema and neurologic complications. This risk is greatest in the patient who has developed hypernatremia over several days or longer. Dietary sodium intake is often restricted.

Hyponatremia

Hyponatremia (low serum sodium) may result from a loss of sodium-containing fluids, water excess in relation to the amount of sodium (dilutional hyponatremia), or a combination of both (see Table 17-4). Common causes of hyponatremia from loss of sodium-rich body fluids include profuse diaphoresis, draining wounds, excessive diarrhea or vomiting, and trauma with significant blood loss. Hyponatremia causes hypoosmolality with a shift of water into the cells.

A common cause of hyponatremia from water excess is inappropriate use of sodium-free or hypotonic IV fluids. This may occur in patients after surgery or major trauma or during administration of fluids in patients with renal failure. Patients with psychiatric disorders may have an excessive water intake. Syndrome of inappropriate antidiuretic hormone secretion (SIADH) will result in dilutional hyponatremia caused by abnormal retention of water. (See Chapter 50 for a discussion of the causes of SIADH.)

Clinical Manifestations. Manifestations of hyponatremia are due to cellular swelling and first manifested in the central nervous system (CNS) (see Table 17-4). The excess water lowers plasma osmolality, shifting fluid into brain cells, causing irritability, headache, confusion, seizures, and even coma. Severe acute hyponatremia, if untreated, can cause irreversible neurologic damage or death.[7]

NURSING AND COLLABORATIVE MANAGEMENT HYPONATREMIA

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with hyponatremia include, but are not limited to, the following:

- Risk for acute confusion *related to* electrolyte imbalance
- Risk for injury *related to* altered sensorium and decreased level of consciousness

- Risk for electrolyte imbalance *related to* excessive loss of sodium and/or excessive intake or retention of water
- Potential complication: severe neurologic changes

NURSING IMPLEMENTATION

In hyponatremia caused by water excess, fluid restriction is often the only treatment. If severe symptoms (seizures) develop, small amounts of IV hypertonic saline solution (3% sodium chloride) can restore the serum sodium level while the body is returning to a normal water balance. Treatment of hyponatremia associated with abnormal fluid loss includes fluid replacement with sodium-containing solutions.

The drugs conivaptan (Vaprisol) and tolvaptan (Samsca) are given to block the activity of ADH. Conivaptan results in increased urine output without loss of electrolytes such as sodium and potassium. It should not be used in patients with hyponatremia from excess water loss. Tolvaptan is used to treat hyponatremia associated with heart failure, liver cirrhosis, and SIADH.[9] Treatment with these drugs is started in a hospital setting so the patient's clinical status and serum sodium levels can be carefully monitored.

POTASSIUM IMBALANCES

Potassium is the major ICF cation, with 98% of the body potassium being intracellular. For example, potassium concentration within muscle cells is approximately 140 mEq/L; potassium concentration in ECF is 3.5 to 5.0 mEq/L. The sodium-potassium pump in cell membranes maintains this concentration difference by pumping potassium into the cell and sodium out. Because the ratio of ECF potassium to ICF potassium is the major factor in the resting membrane potential of nerve and muscle cells, neuromuscular and cardiac function are commonly affected by potassium imbalances.

Disruptions in the dynamic equilibrium between ICF and ECF potassium often cause clinical problems. Potassium regulates intracellular osmolality and promotes cellular growth. Potassium is required for glycogen to be deposited in muscle and liver cells. Potassium also plays a role in acid-base balance (discussed in the section on acid-base regulation later in this chapter).

Diet is the source of potassium. The typical Western diet contains approximately 50 to 100 mEq of potassium daily, mainly from fruits, dried fruits, and vegetables. Many salt substitutes used in low-sodium diets contain substantial potassium. Patients may receive potassium from parenteral sources, including IV fluids; transfusions of stored, hemolyzed blood; and medications (e.g., potassium penicillin).

The kidneys are the primary route for potassium loss, eliminating about 90% of the daily potassium intake. The remainder is lost in the stool and sweat. There is an inverse relationship between sodium and potassium reabsorption in the kidneys. Factors that cause sodium retention (e.g., low blood volume, increased aldosterone level) cause potassium loss in the urine. Large urine volumes can be associated with excess loss of potassium in the urine. If kidney function is significantly impaired, retained potassium can lead to toxic levels.

Hyperkalemia

Hyperkalemia (high serum potassium) may result from impaired renal excretion, a shift of potassium from ICF to ECF, a massive intake of potassium, or a combination of these factors (Table 17-5). The most common cause of hyperkalemia is renal failure. Adrenal insufficiency with a subsequent aldosterone deficiency leads to retention of potassium ions. Factors that cause potassium to move from ICF to ECF include acidosis, massive cell destruction (as in burn or crush injury, tumor lysis, severe infections), and exercise. In metabolic acidosis, potassium ions shift from ICF to ECF in exchange for hydrogen ions moving into the cell.

Both digoxin-like drugs and β-adrenergic blockers (beta blockers) (e.g., propranolol [Inderal]) can impair entry of potassium into cells, resulting in a higher ECF potassium concentration.[10] Certain drugs, such as potassium-sparing diuretics (e.g., amiloride [Midamor]), aldosterone receptor blockers (e.g., spi-

TABLE 17-5 POTASSIUM IMBALANCES: CAUSES AND CLINICAL MANIFESTATIONS

Hyperkalemia (K^+ >5.0 mEq/L [mmol/L])	Hypokalemia (K^+ <3.5 mEq/L [mmol/L])
Causes	
Excess Potassium Intake	***Potassium Loss***
• Excessive or rapid parenteral administration • Potassium-containing drugs (e.g., potassium penicillin) • Potassium-containing salt substitute	• *GI losses:* diarrhea, vomiting, fistulas, NG suction • *Renal losses:* diuretics, hyperaldosteronism, magnesium depletion • *Skin losses:* diaphoresis • Dialysis
Shift of Potassium Out of Cells	***Shift of Potassium Into Cells***
• Acidosis • Tissue catabolism (e.g., fever, sepsis, burns) • Crush injury • Tumor lysis syndrome	• Increased insulin (e.g., IV dextrose load) • Alkalosis • Tissue repair • ↑ Epinephrine (e.g., stress)
Failure to Eliminate Potassium	***Lack of Potassium Intake***
• Renal disease • Potassium-sparing diuretics (e.g., amiloride [Midamor]) • Adrenal insufficiency • ACE inhibitors • NSAIDs	• Starvation • Diet low in potassium • Failure to include potassium in parenteral fluids if NPO
Clinical Manifestations	
• Irritability • Anxiety • Abdominal cramping, diarrhea • Weakness of lower extremities • Paresthesias • Irregular pulse • Cardiac arrest if hyperkalemia sudden or severe	• Fatigue • Muscle weakness, leg cramps • Nausea, vomiting, paralytic ileus • Soft, flabby muscles • Paresthesias, decreased reflexes • Weak, irregular pulse • Polyuria • Hyperglycemia
Electrocardiogram Changes	***Electrocardiogram Changes***
• Tall, peaked T wave • Prolonged PR interval • ST segment depression • Loss of P wave • Widening QRS • Ventricular fibrillation • Ventricular standstill	• ST segment depression • Flattened T wave • Presence of U wave • Prolonged QRS • Ventricular dysrhythmias (e.g., PVCs) • Bradycardia

ACE, Angiotensin-converting enzyme; *PVCs,* premature ventricular contractions.

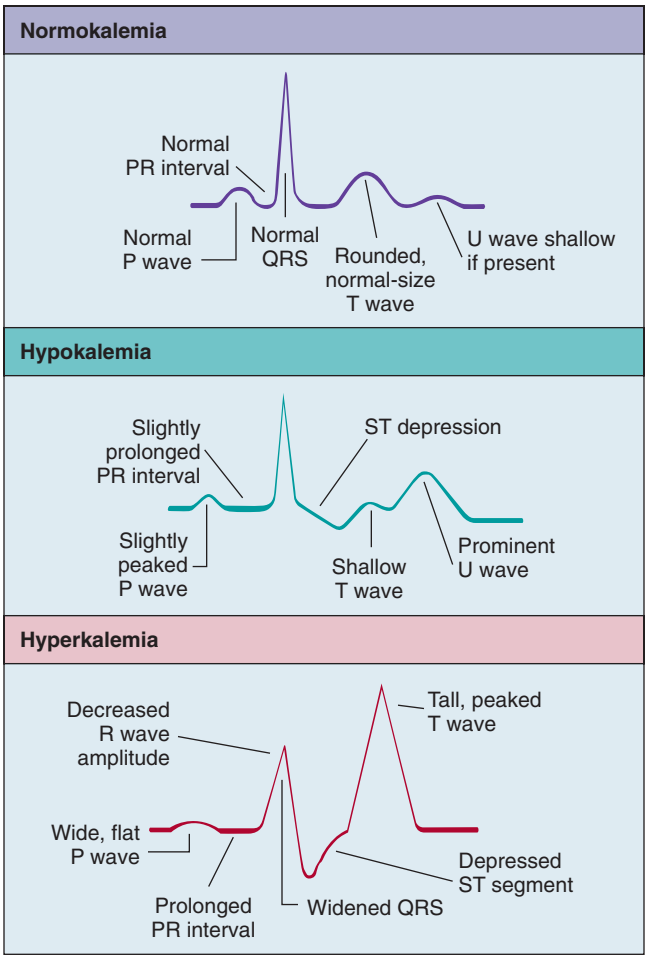

FIG. 17-14 Electrocardiographic changes associated with alterations in potassium status.

ronolactone [Aldactone]), and angiotensin-converting enzyme (ACE) inhibitors (e.g., enalapril [Vasotec], lisinopril [Prinivil]), may contribute to the development of hyperkalemia by reducing the kidney's ability to excrete potassium.

Clinical Manifestations. Hyperkalemia increases the concentration of potassium outside of the cell, altering the normal ECF and ICF ratio and resulting in increased cellular excitability (see Table 17-5). Initially, as the levels of potassium increase, the patient may experience cramping leg pain and weakness, followed by weakness or paralysis of other skeletal muscles, including the respiratory muscles. Abdominal cramping and diarrhea occur from hyperactivity of smooth muscles.

The most clinically significant manifestations of hyperkalemia are the disturbances in cardiac conduction[8] (Fig. 17-14). Cardiac depolarization is decreased, leading to flattening of the P wave and widening of the QRS complex. Repolarization occurs more rapidly, resulting in shortening of the QT interval and a T wave that is narrower and more peaked. Ventricular fibrillation or cardiac standstill may occur.

NURSING AND COLLABORATIVE MANAGEMENT HYPERKALEMIA

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with hyperkalemia include, but are not limited to, the following:

- Risk for activity intolerance *related to* lower extremity muscle weakness
- Risk for electrolyte imbalance *related to* excessive retention or cellular release of potassium
- Risk for injury *related to* lower extremity muscle weakness and seizures
- Potential complication: dysrhythmias

NURSING IMPLEMENTATION

Treatment of hyperkalemia consists of the following:

1. Eliminate oral and parenteral potassium intake (see Table 47-11).
2. Increase elimination of potassium. This is accomplished with diuretics, dialysis, and ion-exchange resins such as sodium polystyrene sulfonate (Kayexalate). Kayexalate, administered orally or rectally, binds potassium in exchange for sodium, and the resin is excreted in feces (see Chapter 47).
3. Force potassium from ECF to ICF. This is accomplished by IV administration of regular insulin (along with glucose so the patient does not become hypoglycemic) or IV sodium bicarbonate for the correction of acidosis. Occasionally, a β-adrenergic agonist (e.g., nebulized albuterol) is administered. This therapy is not indicated for patients with tachycardia or coronary artery disease.
4. Reverse the membrane potential effects of the elevated ECF potassium by administering IV calcium gluconate. Calcium ions can immediately reverse the membrane excitability.

In cases in which the elevation of potassium is mild and the kidneys are functioning, it may be sufficient to (1) withhold potassium from the diet and IV sources and (2) increase renal potassium elimination by administering fluids and loop or thiazide diuretics. Patients with moderate hyperkalemia should additionally receive one of the treatments to force potassium into cells, usually IV insulin and glucose. Monitor the electrocardiograms (ECGs) of all patients with clinically significant hyperkalemia to detect dysrhythmias and to monitor the effects of therapy. The patient experiencing dangerous cardiac dysrhythmias should receive IV calcium gluconate immediately. Monitor blood pressure because rapid administration of calcium can cause hypotension. Hemodialysis is an effective means of removing potassium from the body in the patient with renal failure.

Hypokalemia

Hypokalemia (low serum potassium) can result from increased loss of potassium, from an increased shift of potassium from ECF to ICF, or rarely from deficient dietary potassium intake. The most common causes of hypokalemia are abnormal losses from either the kidneys or the GI tract. GI tract losses of potassium are associated with diarrhea, laxative abuse, vomiting, and ileostomy drainage. Renal losses occur when the patient has a low magnesium level or is diuresing, particularly in the patient with an elevated aldosterone level. Aldosterone is released when the circulating blood volume is low, thus causing sodium retention in the kidneys with a loss of potassium in the urine. Low plasma magnesium stimulates renin release and subsequent increased aldosterone levels, which results in potassium excretion.

Among the factors causing potassium to move from ECF to ICF are insulin therapy (especially in conjunction with diabetic

ketoacidosis) and β-adrenergic stimulation (catecholamine release in stress, coronary ischemia, delirium tremens, administration of β-adrenergic agonist drugs). Alkalosis can cause a shift of potassium into cells in exchange for hydrogen, thus lowering the potassium in ECF and causing symptomatic hypokalemia.

Clinical Manifestations. Hypokalemia alters the resting membrane potential, resulting in hyperpolarization (an increased negative charge within the cell) and impaired muscle contraction. Therefore the manifestations of hypokalemia involve changes in cardiac and muscle function (see Table 17-5).

The most serious clinical problems are cardiac changes, including impaired repolarization, resulting in a flattening of the T wave and eventually in emergence of a U wave. The P waves peak, and the QRS complex is prolonged (see Fig. 17-14). There is an increased incidence of potentially lethal ventricular dysrhythmias.

Skeletal muscle weakness and paralysis may occur with hypokalemia. As with hyperkalemia, hypokalemia initially affects leg muscles. Severe hypokalemia can cause weakness or paralysis of respiratory muscles, leading to shallow respirations and respiratory arrest. Alterations in smooth muscle function may lead to decreased GI motility (e.g., paralytic ileus), decreased airway responsiveness, and impaired regulation of arteriolar blood flow, possibly contributing to smooth muscle cell breakdown. Finally, hypokalemia can impair function in nonmuscle tissue by impairing insulin secretion, leading to hyperglycemia.

NURSING AND COLLABORATIVE MANAGEMENT HYPOKALEMIA

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with hypokalemia include, but are not limited to, the following:

- Risk for activity intolerance *related to* lower extremity muscle weakness
- Risk for electrolyte imbalance *related to* excessive loss of potassium
- Risk for injury *related to* muscle weakness and hyporeflexia
- Potential complication: dysrhythmias

NURSING IMPLEMENTATION

Treatment of hypokalemia consists of oral or IV potassium chloride (KCl) supplements and increased dietary intake of potassium. Except in severe deficiencies, KCl is not given unless there is urine output of at least 0.5 mL/kg of body weight per hour.

SAFETY ALERT

- IV KCl must always be diluted and never given in concentrated amounts.
- Never give KCl via IV push or as a bolus.
- Invert IV bags containing KCl several times to ensure even distribution in the bag.
- Never add KCl to a hanging IV bag to prevent giving a bolus dose.

The preferred maximum concentration is 40 mEq/L. However, stronger concentrations (up to 80 mEq/L) may be given for severe hypokalemia, with continuous cardiac monitoring.[11] The rate of IV administration of KCl should not exceed 10 mEq/hr and must be given by infusion pump to ensure correct administration rate. Because KCl is irritating to the vein, assess IV sites at least hourly for phlebitis and infiltration. Infiltration can cause necrosis and sloughing of the surrounding tissue. Use a central IV line when rapid correction of hypokalemia is necessary.

Patients at risk for hypokalemia and those who are critically ill should have cardiac monitoring to detect cardiac changes related to potassium imbalances. Monitor serum potassium levels and urine output as appropriate. Because patients on digoxin therapy have an increased risk of toxicity if their serum potassium level is low, monitor the patient for digitalis toxicity.

Teach patients methods to prevent hypokalemia (Table 17-6). Foods high in potassium are identified in Table 47-11. Patients at risk for hypokalemia should have regular serum potassium levels monitored.

TABLE 17-6 PATIENT & CAREGIVER TEACHING GUIDE

Prevention of Hypokalemia

When teaching the patient and the caregiver to prevent hypokalemia, do the following.

1. For all patients at risk:
   - Teach the signs and symptoms of hypokalemia (see Table 17-5) and to report them to the health care provider.
2. For patients taking potassium-losing diuretics:*
   - Explain the importance of increasing dietary potassium intake.
   - Teach which foods are high in potassium (see Table 47-11).
   - Explain that salt substitutes contain approximately 50 to 60 mEq of potassium per teaspoon, and help patients raise their potassium levels if taking a potassium-losing diuretic.
3. For patients taking potassium-sparing diuretics:*
   - Instruct the patient and the caregiver to avoid salt substitutes and foods high in potassium.
4. For patients taking oral potassium supplements:
   - Instruct the patient to take the medication as prescribed to prevent overdosage and to take the supplement with a full glass of water to help it dissolve in the GI tract.
5. For patients taking digitalis preparations and others at risk for hypokalemia:
   - Explain the importance of having serum potassium levels regularly monitored because low potassium enhances the action of digitalis.

*For specific information on diuretics, see Table 33-7.

CALCIUM IMBALANCES

Calcium is necessary for many metabolic processes. It is the major cation in the structure of bones and teeth. Other functions of calcium include blood clotting, transmission of nerve impulses, myocardial contractions, and muscle contractions. The source of calcium is dietary intake. Calcium absorption requires the active form of vitamin D. Vitamin D is either ingested in the diet or formed in the skin in the presence of sunlight.

The total body content of calcium is about 1200 g. More than 99% of the body's calcium is found in bones; the remainder is in plasma and body cells. Of the calcium in plasma, 50% is bound to plasma proteins (primarily albumin); 40% is in the free or ionized form; and the remainder is bound with phosphate, citrate, or carbonate. Ionized calcium is the biologically active form.

Calcium is measured in milligrams per deciliter (mg/dL) and milliequivalents per liter (mEq/L). Serum calcium levels usually

TABLE 17-7 CALCIUM IMBALANCES: CAUSES AND CLINICAL MANIFESTATIONS

Hypercalcemia (Ca^{2+} >10.2 mg/dL [2.55 mmol/L])	Hypocalcemia (Ca^{2+} <8.6 mg/dL [2.15 mmol/L])
Causes	
Increased Total Calcium	***Decreased Total Calcium***
• Multiple myeloma • Malignancies with bone metastasis • Prolonged immobilization • Hyperparathyroidism • Vitamin D overdose • Thiazide diuretics • Milk-alkali syndrome	• Chronic kidney disease • Elevated phosphorus • Primary hypoparathyroidism • Vitamin D deficiency • Magnesium deficiency • Acute pancreatitis • Loop diuretics (e.g., furosemide [Lasix]) • Chronic alcoholism • Diarrhea • ↓ Serum albumin (patient is usually asymptomatic due to normal ionized calcium level)
Increased Ionized Calcium	***Decreased Ionized Calcium***
• Acidosis	• Alkalosis • Excess administration of citrated blood
Clinical Manifestations	
• Lethargy, weakness • Depressed reflexes • Decreased memory • Confusion, personality changes, psychosis • Anorexia, nausea, vomiting • Bone pain, fractures • Polyuria, dehydration • Nephrolithiasis • Stupor, coma	• Easy fatigability • Depression, anxiety, confusion • Numbness and tingling in extremities and region around mouth • Hyperreflexia, muscle cramps • Chvostek's sign • Trousseau's sign • Laryngeal spasm • Tetany, seizures
Electrocardiogram Changes	***Electrocardiogram Changes***
• Shortened ST segment • Shortened QT interval • Ventricular dysrhythmias • Increased digitalis effect	• Elongation of ST segment • Prolonged QT interval • Ventricular tachycardia

reflect the total calcium level (all three forms). Ionized calcium levels are analyzed and reported separately. The levels listed in Table 17-7 reflect total calcium levels. Changes in serum pH alter the level of ionized calcium without altering the total calcium level. A decreased plasma pH (acidosis) decreases calcium binding to albumin, leading to more ionized calcium. An increased plasma pH (alkalosis) increases calcium binding, leading to decreased ionized calcium. Alterations in serum albumin levels affect the interpretation of total calcium levels. Low albumin levels result in a drop in the total calcium level, although the level of ionized calcium is not affected.

Calcium balance is controlled by parathyroid hormone (PTH) and calcitonin. Since the bones serve as a readily available store of calcium, the body is usually able to maintain normal serum calcium levels by regulating the movement of calcium into or out of the bone. PTH is produced by the parathyroid gland. Its production and release are stimulated by low serum calcium levels. PTH increases bone resorption (movement of calcium out of bones), increases GI absorption of calcium, and increases renal tubule reabsorption of calcium. Calcitonin is produced by the thyroid gland and is stimulated by high serum calcium levels. It opposes the action of PTH and lowers the serum calcium level by decreasing GI absorption, increasing calcium deposition into bone, and promoting renal excretion.

Hypercalcemia

Hypercalcemia (high serum calcium) is caused by hyperparathyroidism in about two thirds of the cases. Malignancy, especially from myeloma and breast, lung, and kidney cancers, causes the remaining third.[12] Malignancies lead to hypercalcemia through bone destruction from tumor invasion or through tumor secretion of a parathyroid-related protein, which stimulates calcium release from bones. Hypercalcemia is also associated with prolonged immobilization, which results in bone mineral loss and increased plasma calcium concentration. Rare causes include vitamin D overdose or increased calcium intake (e.g., ingestion of antacids containing calcium, excessive administration during cardiac arrest).

Excess calcium leads to reduced excitability of both muscles and nerves. Table 17-7 outlines the causes and clinical manifestations of hypercalcemia.

NURSING AND COLLABORATIVE MANAGEMENT HYPERCALCEMIA

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with hypercalcemia include, but are not limited to, the following:

- Risk for activity intolerance *related to* generalized muscle weakness
- Risk for electrolyte imbalance *related to* excessive bone destruction
- Risk for injury *related to* neuromuscular and sensorium changes
- Potential complication: dysrhythmias

NURSING IMPLEMENTATION

The basic treatment for hypercalcemia is promoting urinary excretion of calcium by administering a loop diuretic (e.g., furosemide [Lasix]) and hydrating the patient with isotonic saline infusions. The patient must drink 3000 to 4000 mL of fluid daily to promote the renal excretion of calcium and decrease the possibility of kidney stone formation. Other supportive measures include a diet low in calcium and an increase in weight-bearing activity to enhance bone mineralization.

Bisphosphonates (e.g., pamidronate [Aredia], zoledronic acid [Zometa]) are the most effective agents in treating hypercalcemia caused by a malignancy.[12] They inhibit the activity of osteoclasts (cells that break down bone and result in calcium release). Synthetic calcitonin given intramuscularly (IM) or subcutaneously lowers serum calcium levels; the intranasal form is not effective.

Hypocalcemia

Hypocalcemia (low serum calcium) can be caused by any condition that decreases the production of PTH. This may occur with surgical removal of a portion of or injury to the parathyroid glands during thyroid or neck surgery. Acute pancreatitis is

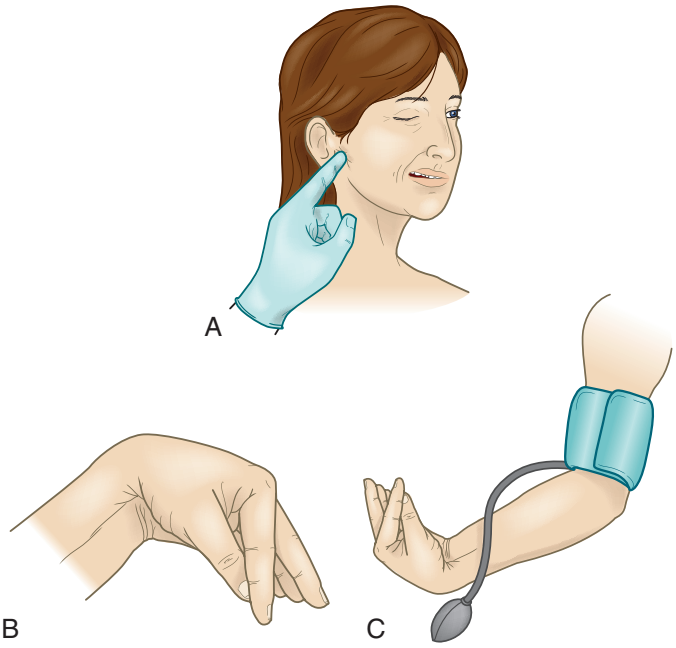

FIG. 17-15 Tests for hypocalcemia. **A,** Chvostek's sign is contraction of facial muscles in response to a light tap over the facial nerve in front of the ear. **B,** Trousseau's sign is a carpal spasm induced by, **C,** inflating a blood pressure cuff above the systolic pressure for a few minutes.

another potential cause of hypocalcemia. Lipolysis, a consequence of pancreatitis, produces fatty acids that combine with calcium ions, decreasing serum calcium levels. The patient who receives multiple blood transfusions can become hypocalcemic because the citrate used to anticoagulate the blood binds with the calcium. Sudden alkalosis may result in symptomatic hypocalcemia despite a normal total serum calcium level. The high pH increases calcium binding to protein, decreasing the amount of ionized calcium. Hypocalcemia can occur if there is increased loss of calcium due to laxative abuse and malabsorption syndromes. (See Table 17-7 for the causes of hypocalcemia.)

Low calcium levels allow sodium to move into excitable cells, decreasing the threshold of action potentials with subsequent depolarization of the cells. This results in increased nerve excitability and sustained muscle contraction, or *tetany.* Clinical signs of tetany include Chvostek's sign and Trousseau's sign. *Chvostek's sign* is contraction of facial muscles in response to a tap over the facial nerve in front of the ear (Fig. 17-15, *A*). *Trousseau's sign* refers to carpal spasms induced by inflating a blood pressure cuff on the arm (Fig. 17-15, *B* and *C*). After the cuff is inflated above the systolic pressure, carpal spasms occur within 3 minutes if hypocalcemia is present. Other manifestations of tetany are laryngeal stridor, dysphagia, and numbness and tingling around the mouth or in the extremities.

Cardiac effects of hypocalcemia include decreased cardiac contractility and ECG changes. A prolonged QT interval may develop into ventricular tachycardia. Table 17-7 outlines the clinical manifestations of hypocalcemia.

NURSING AND COLLABORATIVE MANAGEMENT HYPOCALCEMIA

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with hypocalcemia include, but are not limited to, the following:

- Acute pain *related to* sustained muscle contractions
- Ineffective breathing pattern *related to* laryngospasm
- Risk for electrolyte imbalance *related to* decreased production of PTH
- Risk for injury *related to* tetany and seizures
- Potential complications: fracture, respiratory arrest

NURSING IMPLEMENTATION

The primary goal of treatment of hypocalcemia is to treat the underlying cause. When severe manifestations of hypocalcemia occur, IV preparations of calcium (e.g., calcium gluconate, calcium chloride) are given. Treatment of mild hypocalcemia involves a diet high in calcium-rich foods along with vitamin D supplementation. Oral calcium supplements, such as calcium carbonate, can be used when patients are unable to consume enough dietary calcium, such as those who cannot tolerate dairy products. Measures to promote CO_2 retention, such as breathing into a paper bag or sedating the patient, can control muscle spasm and other symptoms of tetany until the calcium level is corrected. Adequately treat pain and anxiety because hyperventilation-induced respiratory alkalosis can precipitate hypocalcemic symptoms. Closely observe any patient who has had thyroid or neck surgery in the immediate postoperative period for manifestations of hypocalcemia because of the proximity of the surgery to the parathyroid glands.

PHOSPHATE IMBALANCES

Phosphorus is the primary anion in ICF and the second most abundant element in the body, second to calcium. Most phosphorus is in the bones and teeth as calcium phosphate. The remaining phosphorus is metabolically active and essential to the function of muscle, red blood cells (RBCs), and the nervous system. It is also involved in the acid-base buffering system; the mitochondrial formation of ATP; cellular uptake and use of glucose; and the metabolism of carbohydrates, proteins, and fats.

PTH maintains serum phosphorus levels and balance. Regulation of phosphate balance requires adequate renal functioning because the kidneys are the major route of phosphate excretion. When the phosphate level in the glomerular filtrate falls below the normal level or PTH levels are low, the kidneys reabsorb additional phosphorus. A reciprocal relationship exists between phosphorus and calcium in that a high serum phosphate level tends to cause a low calcium concentration in the serum. Low serum calcium levels stimulate the release of PTH, which decreases reabsorption of phosphorus.

Hyperphosphatemia

Hyperphosphatemia (high serum phosphate) is commonly caused by acute kidney injury or chronic kidney disease, which results in an altered ability of the kidneys to excrete phosphate. Other causes include chemotherapy for leukemia or lymphoma, excessive ingestion of milk or phosphate-containing laxatives, and large intakes of vitamin D that increase GI absorption of phosphorus. Table 17-8 summarizes causes and clinical manifestations of hyperphosphatemia.

Mild hyperphosphatemia is often asymptomatic. The clinical manifestations of more severe hyperphosphatemia primarily relate to the low serum calcium levels often associated with high serum phosphate levels. These include tetany, muscle cramps, paresthesias, and seizures. Increased levels of phosphate readily

TABLE 17-8 PHOSPHATE IMBALANCES: CAUSES AND CLINICAL MANIFESTATIONS

Hyperphosphatemia (PO_4^{3-} >4.4 mg/dL [1.42 mmol/L])	Hypophosphatemia (PO_4^{3-} <2.4 mg/dL [0.78 mmol/L])
Causes	
• Renal failure • Chemotherapy drugs • Enemas containing phosphorus (e.g., Fleet Enema) • Excessive ingestion (e.g., milk, phosphate-containing laxatives) • Hypoparathyroidism • Sickle cell anemia	• Malabsorption syndromes • Recovery from malnutrition or refeeding • Glucose or insulin therapy • Total parenteral nutrition • Alcohol withdrawal • Phosphate-binding antacids • Recovery from diabetic ketoacidosis • Respiratory alkalosis
Clinical Manifestations	
• Hypocalcemia • Numbness and tingling in extremities and region around mouth • Hyperreflexia, muscle cramps • Tetany, seizures • Deposition of calcium-phosphate precipitates in skin, soft tissue, cornea, viscera, blood vessels	• CNS depression (confusion, coma) • Muscle weakness, including respiratory muscle weakness and difficulty weaning from ventilator • Polyneuropathy, seizures • Cardiac problems (dysrhythmias, decreased stroke volume) • Osteomalacia • Rhabdomyolysis

precipitate with calcium, and calcified deposits occur outside of the bones. These metastatic calcium precipitates can be found in soft tissues such as joints, arteries, skin, kidneys, and corneas and produce organ dysfunction, notably renal failure (see Chapter 47).

The primary management of hyperphosphatemia is identifying and treating the underlying cause. Ingestion of foods and fluids high in phosphorus (e.g., dairy products) should be restricted. Phosphate-binding agents or gels (e.g., calcium carbonate) limit intestinal phosphate absorption and increase phosphate secretion into the intestine. With severe hyperphosphatemia, hemodialysis or an insulin and glucose infusion can rapidly decrease levels. If hypocalcemia is present, providing adequate hydration and instituting measures to correct calcium levels assist with returning phosphorus levels to normal.

Hypophosphatemia

Hypophosphatemia (low serum phosphate) is rare, but may occur in the patient who is malnourished or has a malabsorption syndrome. Other causes include alcohol withdrawal and use of phosphate-binding antacids. Hypophosphatemia may also occur during parenteral nutrition with inadequate phosphorus replacement. Table 17-8 summarizes causes and clinical manifestations of hypophosphatemia.

Most clinical manifestations of hypophosphatemia result from impaired cellular energy and O_2 delivery due to low levels of cellular ATP and 2,3-diphosphoglycerate (2,3-DPG), an enzyme in RBCs that facilitates O_2 delivery to the tissues. Mild to moderate hypophosphatemia is often asymptomatic. Severe hypophosphatemia may be fatal because of decreased cellular function. Acute manifestations include CNS depression, confusion, and other mental changes. Other manifestations include muscle weakness and pain, dysrhythmias, and cardiomyopathy.

Management of a mild phosphorus deficiency may involve oral supplementation (e.g., Neutra-Phos) and ingestion of foods high in phosphorus (e.g., dairy products). Symptomatic hypophosphatemia can be fatal and often requires IV administration of sodium phosphate or potassium phosphate.[13] Frequent monitoring of serum phosphate and calcium levels is necessary to guide IV therapy. Sudden symptomatic hypocalcemia, secondary to increased calcium phosphorus binding, is a potential complication of IV phosphorus administration.

MAGNESIUM IMBALANCES

Magnesium is the second most abundant intracellular cation. Magnesium plays an important role in many essential cellular processes. The most notable is the activation of a wide variety of enzyme systems. Magnesium is a coenzyme in the metabolism of carbohydrates and protein and is required for the synthesis of nucleic acids and proteins. Magnesium plays a role in maintaining normal calcium and potassium balance. Adequate intracellular magnesium is necessary for normal function of the sodium-potassium pump. Because magnesium acts directly on the myoneural junction, alterations in serum magnesium levels profoundly affect neuromuscular excitability and contractility.

Approximately 50% to 60% of the body's magnesium is contained in bone. Only a small amount (2%) is in ECF, with the remainder inside the cell. Magnesium is regulated by GI absorption and renal excretion. The kidneys are able to conserve magnesium in times of need and excrete excesses. Factors that regulate calcium balance (e.g., PTH) similarly influence magnesium balance. Manifestations of magnesium imbalance are often mistaken for calcium imbalances. Because magnesium, calcium, and potassium balance are closely related, assess all three cations together.[14]

Hypermagnesemia

Hypermagnesemia (high serum magnesium level) usually occurs only with an increase in magnesium intake accompanied by renal insufficiency or failure. (Table 17-9 lists the causes of hypermagnesemia.) A patient with chronic kidney disease who ingests products containing magnesium (e.g., Maalox, milk of magnesia) will have a problem with excess magnesium. Magnesium excess could develop in the pregnant woman who receives magnesium sulfate for the management of eclampsia.

Hypermagnesemia depresses neuromuscular and CNS functions. Initial clinical manifestations of a mildly elevated serum magnesium concentration include lethargy, nausea, and vomiting. As the levels of serum magnesium increase, deep tendon reflexes are lost, followed by somnolence, and then respiratory and, ultimately, cardiac arrest can occur (see Table 17-9).

Management of hypermagnesemia should focus on prevention. People with chronic kidney disease should not take magnesium-containing drugs and should limit ingestion of magnesium containing foods (e.g., green vegetables, nuts, bananas, oranges, peanut butter, chocolate).

The emergency treatment of hypermagnesemia is IV administration of calcium chloride or calcium gluconate to oppose the effects of the magnesium on cardiac muscle. If renal function is adequate, promoting urinary excretion with oral and parenteral fluids and IV furosemide decreases magnesium levels. The

TABLE 17-9 MAGNESIUM IMBALANCES: CAUSES AND CLINICAL MANIFESTATIONS

	Hypermagnesemia (Mg^+ >2.5 mEq/L [1.25 mmol/L])	Hypomagnesemia (Mg^+ <1.5 mEq/L [0.75 mmol/L])
Causes	• Renal failure • Adrenal insufficiency • Excessive administration of magnesium, especially for treatment of eclampsia • Tumor lysis syndrome • Diabetic ketoacidosis	• Diarrhea • Vomiting • Chronic alcoholism • Malabsorption syndromes • Prolonged malnutrition • ↑ Urine output • NG suction • Poorly controlled diabetes mellitus • Hyperaldosteronism
Clinical Manifestations	• Lethargy, drowsiness • Nausea, vomiting • Diminished deep tendon reflexes • Flushed, warm skin • ↓ Pulse, ↓ BP • Muscle weakness • Dysphagia	• Confusion • Tremors, seizures • Hyperactive deep tendon reflexes • Insomnia • ↑ Pulse, ↑ BP • Muscle cramps

patient with impaired renal function requires dialysis because the kidneys are the major route of excretion for magnesium.

Hypomagnesemia

Hypomagnesemia (low serum magnesium level) occurs in patients with limited magnesium intake or increased renal losses. Major causes of hypomagnesemia from insufficient food intake include prolonged fasting or starvation and chronic alcoholism. Fluid loss from the GI tract interferes with magnesium absorption. Another potential cause of hypomagnesemia is prolonged parenteral nutrition without magnesium supplementation. Many diuretics increase the risk of magnesium loss through renal excretion.[14] In addition, osmotic diuresis caused by high glucose levels in uncontrolled diabetes mellitus increases renal excretion of magnesium.

Hypomagnesemia produces neuromuscular and CNS hyperirritability. Clinical manifestations include confusion, hyperactive deep tendon reflexes, muscle cramps, tremors, and seizures. Magnesium deficiency predisposes to cardiac dysrhythmias, such as premature ventricular contractions and ventricular fibrillation. Clinically, hypomagnesemia resembles hypocalcemia and may contribute to the development of hypocalcemia resulting from the decreased action of PTH. Hypomagnesemia may also be associated with hypokalemia that does not respond well to potassium replacement. This occurs because intracellular magnesium is critical to normal function of the sodium-potassium pump.

The primary goal of treatment of hypomagnesemia is to treat the underlying cause. Management of mild magnesium deficiencies involves oral supplements and increased dietary intake of foods high in magnesium. If hypomagnesemia is severe or if hypocalcemia is present, IV magnesium (e.g., magnesium sulfate) is given. Monitor vital signs and use an infusion pump, since too rapid administration of magnesium can lead to cardiac or respiratory arrest.

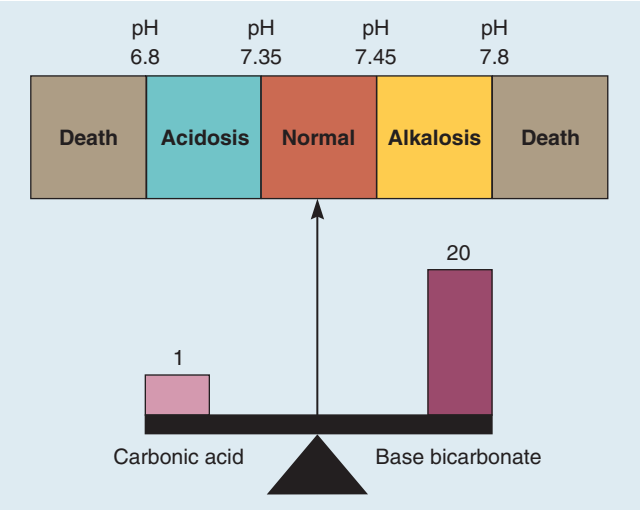

FIG. 17-16 The normal range of plasma pH is 7.35 to 7.45. A normal pH is maintained by a ratio of 1 part carbonic acid to 20 parts bicarbonate.

ACID-BASE IMBALANCES

The body normally maintains a steady balance between the acids produced during normal metabolism and the bases that neutralize and promote the excretion of the acids. Because these acids alter the body's internal environment, their regulation is necessary to maintain homeostasis and acid-base balance. Many health problems may lead to acid-base imbalances. Patients with diabetes mellitus, chronic obstructive pulmonary disease, and kidney disease frequently develop acid-base imbalances. Remember that an acid-base imbalance is not a disease but a symptom of an underlying health problem. Always consider the possibility of acid-base imbalance in patients with serious illnesses.

pH and Hydrogen Ion Concentration

The acidity or alkalinity of a solution depends on its hydrogen ion (H^+) concentration. An increase in H^+ concentration leads to acidity; a decrease leads to alkalinity. Despite the fact that acids are produced by the body daily, the H^+ concentration of body fluids is small (0.0004 mEq/L) and maintained within a narrow range to ensure optimal cellular function.

H^+ concentration is usually expressed as a negative logarithm (symbolized as *pH*) rather than in milliequivalents. The use of the negative logarithm means that the lower the pH, the higher the H^+ concentration. In contrast to a pH of 7, a pH of 8 represents a 10-fold decrease in H^+ concentration.

The pH of a chemical solution may range from 1 to 14. A solution with a pH of 7 is considered neutral. An acid solution has a pH less than 7, and an alkaline solution has a pH greater than 7. Blood is slightly alkaline (pH 7.35 to 7.45). Yet if it drops below 7.35, the person has **acidosis,** even though the blood may never become truly acidic. If the blood pH is greater than 7.45, the person has **alkalosis** (Fig. 17-16).

Acid-Base Regulation

Normally the body has three mechanisms by which it regulates the acid-base balance to maintain the arterial pH between 7.35 and 7.45. These mechanisms are the buffer systems, the respiratory system, and the renal system. The regulatory mechanisms react at different speeds. Buffers react immediately. The respira-

tory system responds in minutes and reaches maximum effectiveness in hours. The renal response takes 2 or 3 days to respond maximally, but the kidneys can maintain balance indefinitely in patients with chronic imbalances.

Buffer System. The buffer system is the fastest-acting system and the primary regulator of acid-base balance. **Buffers** act chemically to change strong acids into weaker acids or to bind acids to neutralize their effect. This minimizes the effect of acids on blood pH until their excretion from the body. The body buffers an acid load better than it neutralizes base excess. Buffers cannot maintain pH without the adequate functioning of the respiratory and renal systems.

A buffer consists of a weakly ionized acid or a base and its salt. The buffers in the body include carbonic acid–bicarbonate, monohydrogen–dihydrogen phosphate, intracellular and plasma protein, and hemoglobin buffers. The cell can also act as a buffer by shifting hydrogen in and out of the cell. With an accumulation of H^+ in ECF, the cells can accept H^+ in exchange for another cation (e.g., potassium ion).

The carbonic acid–bicarbonate (H_2CO_3/HCO_3^-) buffer system neutralizes hydrochloric acid (HCl) in the following manner:

$$\underset{\text{Strong acid}}{HCl} + \underset{\text{Strong base}}{NaH_2CO_3} \rightarrow \underset{\text{Salt}}{NaCl} + \underset{\text{Weak acid}}{H_2CO_3}$$

In this way, combining a strong acid with a strong base prevents the acid from making a large change in the blood's pH. The carbonic acid is broken down to H_2O and CO_2. The lungs excrete CO_2, either combined with insensible H_2O as carbonic acid, or alone as CO_2. In this process, the buffer system maintains a 20:1 ratio between bicarbonate and carbonic acid and the normal pH.

The phosphate buffer system is composed of sodium and other cations in combination with monohydrogen phosphate (HPO_4^{2-}) or dihydrogen phosphate ($H_2PO_4^-$). This intracellular buffer system acts in the same manner as the bicarbonate system. Bases neutralize strong acids, forming sodium chloride (NaCl) and sodium biphosphate (NaH_2PO_4), a weaker acid. Conversely, if a strong base, such as sodium hydroxide (NaOH), is present, sodium dihydrogen phosphate (NaH_2PO_4) neutralizes it to a weaker base (Na_2HPO_4) and H_2O.

The intracellular and extracellular protein buffering system acts like the bicarbonate system. Some of the amino acids of proteins contain free acid radicals (–COOH), which can dissociate into CO_2 and H^+. Other amino acids have basic radicals (NH_3OH [ammonium hydroxide]), which can dissociate into NH_3^+ (ammonia) and OH^- (hydroxide). The OH^- can combine with an H^+ to form H_2O. Hemoglobin is a protein and assists in regulation of pH by shifting chloride in and out of RBCs in exchange for bicarbonate.

Respiratory System. The lungs help maintain a normal pH by excreting CO_2 and water, which are by-products of cellular metabolism. When released into the circulation, CO_2 enters RBCs and combines with H_2O to form H_2CO_3. This carbonic acid dissociates into H^+ and HCO_3^-. Hemoglobin buffers the free H^+, and the HCO_3^- diffuses into the plasma. This process is reversed in the pulmonary capillaries, forming CO_2 that is then excreted by the lungs. The overall reversible reaction is expressed in the following manner:

$$CO_2 + H_2O \rightarrow H_2CO_3 \rightarrow H^+ + HCO_3^-$$

The amount of CO_2 in the blood directly relates to carbonic acid concentration and subsequently to H^+ concentration. With increased respirations, more CO_2 is expelled and less remains in the blood. This leads to less carbonic acid and less H^+. With decreased respirations, more CO_2 remains in the blood. This leads to increased carbonic acid and more H^+.

The respiratory center in the medulla in the brainstem controls the rate of excretion of CO_2. If increased amounts of CO_2 or H^+ are present, the respiratory center stimulates an increased rate and depth of breathing. If the center senses low H^+ or CO_2 levels, respirations are inhibited.

As a compensatory mechanism, the respiratory system acts on the $CO_2 + H_2O$ side of the reaction by altering the rate and depth of breathing to "blow off" (through hyperventilation) or "retain" (through hypoventilation) CO_2. If a respiratory problem (e.g., respiratory failure) is the cause of an acid-base imbalance, the respiratory system loses its ability to correct a pH alteration. The older adult has impaired compensatory ability because of decreased respiratory function.

Renal System. Under normal conditions, the body depends on the kidneys to reabsorb and conserve all of the HCO_3^- they filter and excrete a portion of the acid produced by cellular metabolism. The three mechanisms of acid elimination are (1) secretion of small amounts of free hydrogen into the renal tubule, (2) combination of H^+ with ammonia (NH_3) to form ammonium (NH_4^+), and (3) excretion of weak acids.

The kidneys normally excrete acidic urine (average pH is 6). As a compensatory mechanism, the pH of the urine can decrease to 4 or increase to 8. To compensate for acidosis, the kidneys can reabsorb additional HCO_3^- and eliminate excess H^+. Thus the pH of the blood increases and the pH of the urine decreases. If the renal system is the cause of an acid-base imbalance (e.g., renal failure), it loses its ability to correct a pH alteration. In the older adult the kidneys are less able to compensate for an acid load.

Alterations in Acid-Base Balance

An acid-base imbalance results when there is an alteration in the ratio of 20:1 between base and acid content. This occurs when a primary disease or process alters one side of the ratio (e.g., CO_2 retention in pulmonary disease) and the compensatory processes that maintain the other side of the ratio (e.g., increased renal HCO_3^- reabsorption) either fail or are inadequate. The compensatory process may be inadequate because either the pathophysiologic process is overwhelming or there is insufficient time for the compensatory process to function.

Acid-base imbalances are classified as respiratory or metabolic. *Respiratory imbalances* result from the retention or an excess of CO_2 altering carbonic acid concentrations; *metabolic imbalances* affect the base HCO_3^-. Therefore acidosis is caused by an increase in carbonic acid (respiratory acidosis) or a decrease in HCO_3^- (metabolic acidosis). Alkalosis is caused by a decrease in carbonic acid (respiratory alkalosis) or an increase in HCO_3^- (metabolic alkalosis). Imbalances may be further classified as acute or chronic. Chronic imbalances allow greater time for compensatory changes.

Respiratory Acidosis. *Respiratory acidosis* (carbonic acid excess) occurs whenever the person hypoventilates (Table 17-10). Hypoventilation leads to a buildup of CO_2, resulting in an accumulation of carbonic acid in the blood. Carbonic acid dissociates, liberating H^+, and there is a decrease in pH. If CO_2

TABLE 17-10 ACID-BASE IMBALANCES

Common Causes	Pathophysiology	Laboratory Findings
Respiratory Acidosis		
Chronic obstructive pulmonary disease Barbiturate or sedative overdose Chest wall abnormality Severe pneumonia Atelectasis Respiratory muscle weakness (e.g., Guillain-Barré syndrome) Mechanical hypoventilation	CO_2 retention from hypoventilation Compensatory response is HCO_3^- retention by kidney	↓ Plasma pH ↑ $PaCO_2$ HCO_3^- normal (uncompensated) ↑ HCO_3^- (compensated) *Sample ABG* Uncompensated: pH 7.31 $PaCO_2$ 54 mm Hg HCO_3^- 25 mEq/L
Respiratory Alkalosis		
Hyperventilation (e.g., hypoxia, pulmonary emboli, anxiety, fear, pain, exercise, fever) Stimulated respiratory center (e.g., septicemia, encephalitis, brain injury, salicylate poisoning) Mechanical hyperventilation	Increased CO_2 excretion from hyperventilation Compensatory response is HCO_3^- excretion by kidney	↑ Plasma pH ↓ $PaCO_2$ HCO_3^- normal (uncompensated) ↓ HCO_3^- (compensated) *Sample ABG* Uncompensated: pH 7.52 $PaCO_2$ 27 mm Hg HCO_3^- 24 mEq/L
Metabolic Acidosis		
Diabetic ketoacidosis Lactic acidosis Starvation Severe diarrhea Renal tubular acidosis Renal failure Gastrointestinal fistulas Shock	Gain of fixed acid, inability to excrete acid or loss of base Compensatory response is CO_2 excretion by lungs	↓ Plasma pH $PaCO_2$ normal (uncompensated) ↓ $PaCO_2$ (compensated) ↓ HCO_3^- *Sample ABG* Uncompensated: pH 7.29 $PaCO_2$ 38 mm Hg HCO_3^- 18 mEq/L
Metabolic Alkalosis		
Severe vomiting Excess gastric suctioning Diuretic therapy Potassium deficit Excess $NaHCO_3$ intake Excessive mineralocorticoids	Loss of strong acid or gain of base Compensatory response is CO_2 retention by lungs	↑ Plasma pH $PaCO_2$ normal (uncompensated) ↑ $PaCO_2$ (compensated) ↑ HCO_3^- *Sample ABG* Uncompensated: pH 7.50 $PaCO_2$ 40 mm Hg HCO_3^- 34 mEq/L

ABG, Arterial blood gas.

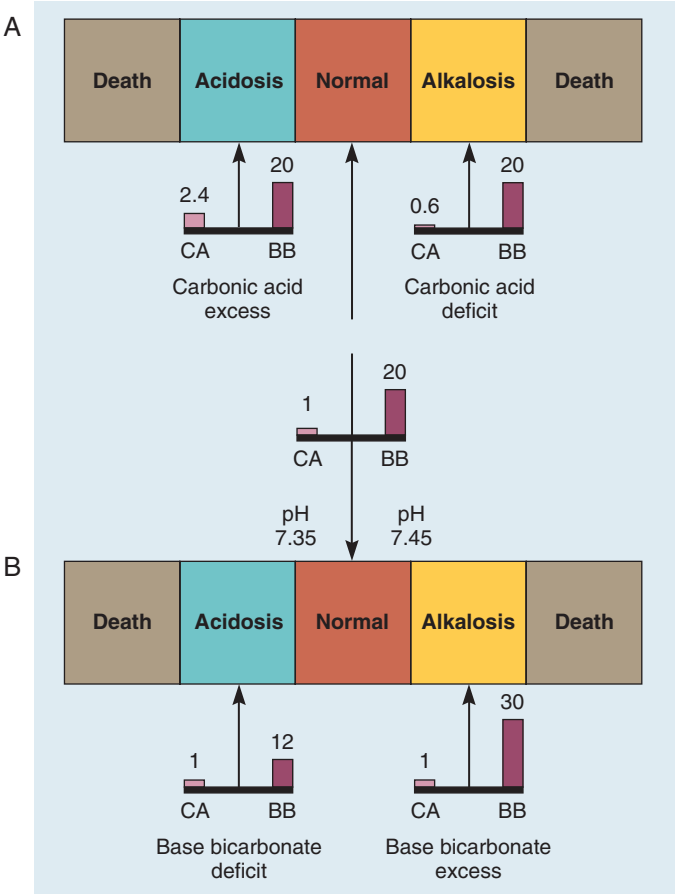

FIG. 17-17 Kinds of acid-base imbalances. **A,** Respiratory imbalances caused by carbonic acid *(CA)* excess and carbonic acid deficit. **B,** Metabolic imbalances caused by base bicarbonate *(BB)* deficit and base bicarbonate excess.

is not eliminated from the blood, acidosis results from the accumulation of carbonic acid (Fig. 17-17, *A*).

To compensate, the kidneys conserve HCO_3^- and secrete increased concentrations of H^+ into the urine. During acute respiratory acidosis, the renal compensatory mechanisms begin to operate within 24 hours. Until the renal mechanisms have an effect, the serum HCO_3^- level will usually be normal.

Respiratory Alkalosis. *Respiratory alkalosis* (carbonic acid deficit) occurs with hyperventilation (see Table 17-10). The primary cause of respiratory alkalosis is hypoxemia from acute pulmonary disorders. Anxiety, CNS disorders, and mechanical overventilation also increase the ventilation rate. The decrease in the partial pressure of arterial CO_2 ($PaCO_2$) level leads to decreased carbonic acid concentration and alkalosis (see Fig. 17-17, *A*).

Compensated respiratory alkalosis is rare. In acute respiratory alkalosis, aggressive treatment of the causes of hypoxemia is essential and usually does not allow time for compensation to occur. However, buffering of acute respiratory alkalosis may occur with shifting of HCO_3^- into cells in exchange for chloride ions (Cl^-). In chronic respiratory alkalosis that occurs with pulmonary fibrosis or CNS disorders, compensation may include renal excretion of HCO_3^-.

Metabolic Acidosis. *Metabolic acidosis* (base bicarbonate deficit) occurs when an acid other than carbonic acid accumulates in the body or when bicarbonate is lost from body fluids (see Table 17-10 and Fig. 17-17, *B*). Ketoacid accumulation in diabetic ketoacidosis and lactic acid accumulation with shock are examples of accumulation of acids. Severe diarrhea results in loss of HCO_3^-. In renal disease the kidneys lose their ability to reabsorb HCO_3^- and secrete H^+.

The compensatory response to metabolic acidosis is to increase CO_2 excretion by the lungs. The patient often develops

Kussmaul respiration (deep, rapid breathing). In addition, the kidneys attempt to excrete additional acid.

If metabolic acidosis is present, calculating the anion gap can help determine the source of the acidosis. The *anion gap* is the difference between the cations and the anions in ECF that are routinely measured. You calculate an anion gap by summing the chloride and bicarbonate levels and subtracting this number from the plasma sodium concentration. Ordinarily, the sum of the measured cations is greater than the sum of the measured anions. The anion gap is normally 10 to 14 mmol/L. The anion gap is increased in metabolic acidosis associated with acid gain (e.g., lactic acidosis, diabetic ketoacidosis) but remains normal in metabolic acidosis caused by bicarbonate loss (e.g., diarrhea).

Metabolic Alkalosis. *Metabolic alkalosis* (base bicarbonate excess) occurs when a loss of acid (e.g., from prolonged vomiting or gastric suction) or a gain in bicarbonate (e.g., from ingestion of baking soda) occurs (see Table 17-10 and Fig. 17-17, *B*). Renal excretion of bicarbonate occurs in response to metabolic alkalosis. The compensatory response to metabolic alkalosis is limited. There is a decreased respiratory rate to increase plasma CO_2. However, once plasma CO_2 reaches a certain level, stimulation of chemoreceptors results in ventilation.

Mixed Acid-Base Disorders. A mixed acid-base disorder occurs when two or more disorders are present at the same time. The pH depends on the type, severity, and acuity of each of the disorders involved and any compensatory mechanisms at work. Respiratory acidosis combined with metabolic alkalosis (e.g., a patient with chronic obstructive pulmonary disease also treated with a thiazide diuretic) may result in a near-normal pH, whereas respiratory acidosis combined with metabolic acidosis will cause a greater decrease in pH than either disorder alone. An example of a mixed acidosis is a patient in cardiopulmonary arrest. An example of a mixed alkalosis is a patient who is hyperventilating because of postoperative pain and losing acid secondary to nasogastric suctioning.

Clinical Manifestations

Clinical manifestations of acidosis and alkalosis are summarized in Tables 17-11 and 17-12. In both respiratory and metabolic acidosis, the CNS is depressed. Headache, lethargy, weakness, and confusion develop, leading eventually to coma and death. In both types of alkalosis, irritability of the CNS causes tingling and numbness of the fingers, restlessness, and tetany. If the severity of alkalosis increases, convulsions and coma may occur.[7]

The compensatory mechanisms also produce specific clinical manifestations. For example, the deep, rapid respirations of a patient with metabolic acidosis are an example of respiratory compensation. In alkalosis, hypocalcemia occurs due to increased calcium binding with albumin, lowering the amount of ionized, biologically active calcium. The hypocalcemia accounts for many of the clinical manifestations of alkalosis.

Blood Gas Values. Arterial blood gas (ABG) values provide objective information about a patient's acid-base status, the underlying cause of an imbalance, the body's ability to regulate pH, and the patient's overall O_2 status. Knowledge of the patient's clinical situation and the physiologic extent of renal and respiratory compensation enables you to identify acid-base disorders, as well as the patient's ability to compensate. Blood gas analysis also shows the partial pressure of arterial O_2 (PaO_2) and O_2 saturation. These values are used to identify hypoxemia.

TABLE 17-11 CLINICAL MANIFESTATIONS OF ACIDOSIS

Respiratory (↑ $PaCO_2$)	Metabolic (↓ HCO_3^-)
Neurologic	
Drowsiness	Drowsiness
Confusion	Confusion
Dizziness	Dizziness
Headache	Headache
Coma	Coma
Cardiovascular	
↓ BP	↓ BP
Ventricular fibrillation (related to hyperkalemia from compensation)	Dysrhythmias (related to hyperkalemia from compensation)
Warm, flushed skin (related to peripheral vasodilation)	Warm, flushed skin (related to peripheral vasodilation)
Gastrointestinal	
No significant findings	Nausea, vomiting, diarrhea, abdominal pain
Neuromuscular	
Seizures	No significant findings
Respiratory	
Hypoventilation with hypoxia (lungs are unable to compensate when there is a respiratory problem)	Deep, rapid respirations (compensatory action by the lungs)

TABLE 17-12 CLINICAL MANIFESTATIONS OF ALKALOSIS

Respiratory (↓ $PaCO_2$)	Metabolic (↑ HCO_3^-)
Neurologic	
Dizziness	Dizziness
Light-headedness	Light-headedness
Confusion	Confusion
Headache	Headache
Cardiovascular	
Tachycardia	Tachycardia
Dysrhythmias (related to hypokalemia from compensation)	Dysrhythmias (related to hypokalemia from compensation)
Gastrointestinal	
Nausea	Nausea
Vomiting	Vomiting
Epigastric pain	Anorexia
Neuromuscular	
Tetany	Tetany
Numbness	Tremors
Tingling of extremities	Tingling of fingers and toes
Hyperreflexia	Muscle cramps, hypertonic muscles
Seizures	Seizures
Respiratory	
Hyperventilation (lungs are unable to compensate when there is a respiratory problem)	Hypoventilation (compensatory action by the lungs)

To interpret the results of an ABG, perform the following six steps:

1. Determine whether the pH is acidotic or alkalotic. Label values less than 7.35 as acidotic and values greater than 7.45 as alkalotic.
2. Analyze the $PaCO_2$ to determine if the patient has respiratory acidosis or alkalosis. Since the lungs control $PaCO_2$, it is the respiratory component of the ABG. Because CO_2 forms carbonic acid when dissolved in blood, high $PaCO_2$ levels indicate acidosis, and low $PaCO_2$ levels indicate alkalosis.
3. Analyze the HCO_3^- level to determine if the patient has metabolic acidosis or alkalosis. Since the kidneys primarily control HCO_3^-, it is the metabolic component of the ABG. Because HCO_3^- is a base, high levels of HCO_3^- result in alkalosis and low levels result in acidosis.
4. At this point, if the pH is between 7.35 and 7.45, and the CO_2 and the HCO_3^- are within normal limits, the ABGs are normal.
5. Determine if the CO_2 or the HCO_3^- matches the acid or base alteration of the pH. For example, if the pH is acidotic (less than 7.35) and the CO_2 is high (respiratory acidosis) but the HCO_3^- is high (metabolic alkalosis), the CO_2 is the parameter that matches the pH alteration of acidosis. The patient's acid-base imbalance is diagnosed as respiratory acidosis.
6. Determine if the body is attempting to compensate for the pH change. If the parameter that does not match the pH is moving in the opposite direction, the body is attempting to compensate. In the example in step 5, the HCO_3^- level is alkalotic; this is in the opposite direction of respiratory acidosis and considered compensation. If compensatory mechanisms are functioning, the pH will return toward 7.40. When the pH is within normal limits, the patient has *full compensation*.

Table 17-13 lists normal blood gas values, and Table 17-14 explains how to analyze ABG results. The laboratory findings section of Table 17-10 provides ABG findings of the four major acid-base disturbances. Table 17-15 shows ROME, a quick memory device (mnemonic) for understanding acid-base imbalances. See Chapter 26 for further discussion of blood gases.

ASSESSMENT OF FLUID, ELECTROLYTE, AND ACID-BASE IMBALANCES

Assessing patients for fluid, electrolyte, and acid-base imbalances is an important part of your nursing practice. Clinical manifestations for specific imbalances are presented earlier in this chapter. In addition to assessing for those clinical manifestations, obtain subjective and objective data from any patient with suspected fluid, electrolyte, or acid-base imbalances as outlined below.

TABLE 17-13 NORMAL ARTERIAL BLOOD GAS VALUES*

Parameter	Reference Interval
pH	7.35-7.45
$PaCO_2$	35-45 mm Hg
Bicarbonate (HCO_3^-)	22-26 mEq/L (mmol/L)
PaO_2†	80-100 mm Hg
SaO_2	>95%
Base excess	±2.0 mEq/L

*Venous blood gas reference intervals are listed in Table 26-1.
†Decreases above sea level and with increasing age.
$PaCO_2$, Partial pressure of CO_2 in arterial blood; *PaO_2*, partial pressure of O_2 in arterial blood; *SaO_2*, arterial O_2 saturation.

Subjective Data

Important Health Information

Past Health History. Question the patient about any past history of problems involving the kidneys, heart, GI system, or lungs that could affect the present fluid, electrolyte, and acid-base balance. Obtain information about specific diseases such as diabetes mellitus, diabetes insipidus, chronic obstructive pulmonary disease, renal failure, ulcerative colitis, and Crohn's disease. Ask the patient about any prior fluid, electrolyte, or acid-base disorders.

Medications. Assess the patient's current and past use of medications. The ingredients in many drugs, especially over-the-counter drugs, are often missed as sources of sodium, potassium, calcium, magnesium, and other electrolytes. Many prescription drugs, including diuretics, corticosteroids, and electrolyte supplements, can cause fluid and electrolyte imbalances.

Surgery or Other Treatments. Ask the patient about past or present renal dialysis, kidney surgery, or bowel surgery resulting

TABLE 17-14 ARTERIAL BLOOD GAS (ABG) ANALYSIS

ABG Values	Analysis
pH 7.30 $PaCO_2$ 25 mm Hg HCO_3^- 16 mEq/L	1. pH <7.35 indicates acidosis. 2. $PaCO_2$ is low, indicating respiratory alkalosis. 3. HCO_3^- is low, indicating metabolic acidosis. 4. Metabolic acidosis matches the pH. 5. The CO_2 does not match, but is moving in the opposite direction, which indicates the lungs are attempting to compensate for the metabolic acidosis.

Interpretation
This ABG is interpreted as metabolic acidosis with partial compensation. If the pH returns to the normal range, the patient is said to have full compensation.

TABLE 17-15 ROME: MEMORY DEVICE FOR ACID-BASE IMBALANCES

For acid-base imbalances a quick memory device (mnemonic) can be used.
In ***Respiratory*** conditions, the pH and the $PaCO_2$ go in ***Opposite*** directions.
- In respiratory alkalosis, the pH is ↑ and the $PaCO_2$ is ↓.
- In respiratory acidosis the pH is ↓ and the $PaCO_2$ is ↑.

In ***Metabolic*** conditions, the pH and the HCO_3^- go in the same direction (equal or ***Equivalent***). The $PaCO_2$ may also go in the same direction.
- In metabolic alkalosis, pH and HCO_3^- are ↑ and the $PaCO_2$ is ↑ or normal.
- In metabolic acidosis, pH and HCO_3^- are ↓ and the $PaCO_2$ is ↓ or normal.

Respiratory		**pH**	**$PaCO_2$**
Opposite	Acidosis	↓	↑
	Alkalosis	↑	↓
Metabolic		**pH**	**HCO_3^-**
Equivalent	Acidosis	↓	↓
	Alkalosis	↑	↑

in a temporary or permanent external collecting system such as a colostomy.

Functional Health Patterns

Health Perception–Health Management Pattern. If the patient is currently experiencing a problem related to fluid, electrolyte, and acid-base balance, obtain a careful description of the illness, including onset, course, and treatment. Question the patient about any recent changes in body weight.

Nutritional-Metabolic Pattern. Ask the patient about diet and any special dietary practices. Weight reduction diets, fad diets, or any eating disorders, such as anorexia or bulimia, can lead to fluid and electrolyte problems. If the patient is on a special diet, such as low sodium or high potassium, assess the ability to adhere to the dietary prescription.

Elimination Pattern. Make note of the patient's usual bowel and bladder habits. Carefully document any deviations from the expected elimination pattern, such as diarrhea, oliguria, nocturia, polyuria, or incontinence.

Activity-Exercise Pattern. Inquire about the patient's exercise pattern and any complaints of excessive perspiration. Determine if the patient is exposed to extremely high temperatures as a result of leisure or work activity. Ask the patient what he or she does to replace fluid and electrolytes lost through excessive perspiration. Assess the patient's activity level to determine any functional problems that could lead to lack of ability to obtain food or fluids.

Cognitive-Perceptual Pattern. Ask about any changes in sensations, such as numbness, tingling, *fasciculations* (uncoordinated twitching of a single muscle group), or muscle weakness, that could indicate a fluid and electrolyte problem. Additionally, ask both the patient and the caregiver if there have been any changes in mentation or alertness, such as confusion, memory impairment, or lethargy.

Objective Data

Physical Examination. A complete physical examination is needed because fluid, electrolyte, and acid-base balance affects all body systems. As you assess each system, check for manifestations that you would expect with an imbalance. Common abnormal assessment findings of major body systems offer clues to possible imbalances (Table 17-16).

Laboratory Values. Assessment of serum electrolyte values is a good starting point for identifying fluid and electrolyte imbalance (see Table 17-1). However, serum electrolyte values often provide only limited information. They reflect the concentration of that electrolyte in ECF but not necessarily in ICF. For example, most of the potassium in the body is found intracellularly. Changes in serum potassium values may be the result of a true deficit or excess of potassium or may reflect the movement of potassium into or out of the cell during acid-base imbalances. An abnormal serum sodium level may reflect a sodium problem or, more likely, a water problem.

In addition to arterial and venous blood gases, serum electrolytes can provide important information about a patient's acid-base balance. Changes in the serum HCO_3^- (often reported as total CO_2 or CO_2 content on an electrolyte panel) indicate metabolic acidosis (low HCO_3^- level) or alkalosis (high HCO_3^- level).

Other laboratory tests helpful in evaluating the presence of or risk for fluid, electrolyte, and acid-base imbalances include serum and urine osmolality, serum glucose, blood urea nitrogen, serum creatinine, venous blood gas sampling, urine specific gravity, and urine electrolytes.

TABLE 17-16 ASSESSMENT ABNORMALITIES

Fluid and Electrolyte Imbalances

Finding	Possible Etiology
Skin	
Poor skin turgor	Fluid volume deficit
Cold, clammy skin	Na^+ deficit, shift of plasma to interstitial fluid
Pitting edema	Fluid volume excess
Flushed, dry skin	Na^+ excess
Pulse	
Bounding pulse	Fluid volume excess, shift of interstitial fluid to plasma
Rapid, weak, thready pulse	Shift of plasma to interstitial fluid, Na^+ deficit, fluid volume deficit
Weak, irregular, rapid pulse	Severe K^+ deficit
Weak, irregular, slow pulse	Severe K^+ excess
Blood Pressure	
Hypotension	Fluid volume deficit, shift of plasma to interstitial fluid, Na^+ deficit
Hypertension	Fluid volume excess, shift of interstitial fluid to plasma
Respirations	
Deep, rapid breathing	Compensation for metabolic acidosis
Shallow, slow, irregular breathing	Compensation for metabolic alkalosis
Shortness of breath	Fluid volume excess
Moist crackles	Fluid volume excess, shift of interstitial fluid to plasma
Restricted airway	Ca^{2+} deficit
Skeletal Muscles	
Cramping of exercised muscle	Ca^{2+} deficit, Mg^{2+} deficit, alkalosis
Carpal spasm (Trousseau's sign)	Ca^{2+} deficit, Mg^{2+} deficit, alkalosis
Flabby muscles	K^+ deficit
Positive Chvostek's sign	Ca^{2+} deficit, Mg^{2+} deficit, alkalosis
Behavior or Mental State	
Picking at bedclothes	K^+ deficit, Mg^{2+} deficit
Indifference	Fluid volume deficit, Na^+ deficit
Apprehension	Shift of plasma to interstitial fluid
Extreme restlessness	K^+ excess, Na^+ excess, fluid volume deficit
Confusion and irritability	K^+ deficit, fluid volume excess, Ca^{2+} excess, Mg^{2+} excess, H_2O excess, Na^+ deficit
Decreased level of consciousness	Na^+ deficit, H_2O excess

ORAL FLUID AND ELECTROLYTE REPLACEMENT

In all cases of fluid, electrolyte, and acid-base imbalances, the primary treatment involves correction of the underlying cause. Oral rehydration solutions containing water, potassium, sodium, and glucose may be used to correct mild fluid and electrolyte deficits. Glucose not only provides calories but also promotes sodium and water absorption in the small intestine. Commercial oral rehydration solutions are now available for home use.

Cola drinks are avoided because they do not contain adequate electrolyte replacement and the sugar content may lead to osmotic diuresis.

INTRAVENOUS FLUID AND ELECTROLYTE REPLACEMENT

IV fluid and electrolyte therapy is necessary to treat many different fluid and electrolyte imbalances. Many patients need maintenance IV fluid therapy while they cannot take oral fluids (e.g., during and after surgery). Other patients need corrective or replacement therapy for losses that have already occurred. The amount and type of solution are determined by the normal daily maintenance requirements and by imbalances identified by laboratory results. IV replacement solutions are classified by their concentration or tonicity (Table 17-17). Tonicity is an important factor in determining the appropriate solution to correct water and solute imbalances.

Solutions

Hypotonic. A hypotonic solution provides more water than electrolytes, diluting the ECF. Osmosis then produces a movement of water from ECF to ICF. After achieving osmotic equilibrium, ICF and ECF have the same osmolality and both compartments are expanded. Table 17-17 gives examples of commonly used hypotonic fluids. Maintenance fluids are usually hypotonic solutions (e.g., 0.45% NaCl) because normal daily losses are hypotonic. Additional electrolytes (e.g., KCl) may be added to maintain normal levels. Because hypotonic solutions have the potential to cause cellular swelling, monitor patients for changes in mentation that may indicate cerebral edema.[15]

Although 5% dextrose in water is considered an isotonic solution, the dextrose is quickly metabolized, and the net result is the administration of free water (hypotonic) with proportionately equal expansion of ECF and ICF. One liter of a 5% dextrose solution provides 50 g of dextrose, or 170 calories. Although this amount of dextrose is not enough to meet caloric requirements, it helps prevent ketosis associated with starvation.

Isotonic. Administration of an isotonic solution expands only ECF. There is no net loss or gain from ICF. An isotonic solution is the ideal fluid replacement for a patient with an ECF volume deficit. Examples of isotonic solutions include lactated Ringer's solution and 0.9% NaCl. Lactated Ringer's solution

TABLE 17-17 COMMONLY USED CRYSTALLOID SOLUTIONS

Solution	Tonicity	mOsm/kg	Glucose (g/L)	Indications and Considerations
Dextrose in Water				
5%	Isotonic, but physiologically hypotonic	278	50	• Provides free water necessary for renal excretion of solutes • Used to replace water losses and treat hypernatremia • Provides 170 cal/L • Does not provide any electrolytes
10%	Hypertonic	556	100	• Provides free water only, no electrolytes • Provides 340 cal/L
Saline				
0.45%	Hypotonic	154	0	• Provides free water in addition to Na^+ and Cl^- • Used to replace hypotonic fluid losses • Used as maintenance solution, although it does not replace daily losses of other electrolytes • Provides no calories
0.9%	Isotonic	308	0	• Used to expand intravascular volume and replace extracellular fluid losses • Only solution that may be administered with blood products • Contains Na^+ and Cl^- in excess of plasma levels • Does not provide free water, calories, other electrolytes • May cause intravascular overload or hyperchloremic acidosis
3.0%	Hypertonic	1026	0	• Used to treat symptomatic hyponatremia • Must be administered slowly and with extreme caution because it may cause dangerous intravascular volume overload and pulmonary edema
Dextrose in Saline				
5% in 0.225%	Isotonic	355	50	• Provides Na^+, Cl^-, and free water • Used to replace hypotonic losses and treat hypernatremia • Provides 170 cal/L
5% in 0.45%	Hypertonic	432	50	• Same as 0.45% NaCl except provides 170 cal/L
5% in 0.9%	Hypertonic	586	50	• Same as 0.9% NaCl except provides 170 cal/L
Multiple Electrolyte Solutions				
Ringer's solution	Isotonic	309	0	• Similar in composition to plasma except that it has excess Cl^-, no Mg^{2+}, and no HCO_3^- • Does not provide free water or calories • Used to expand the intravascular volume and replace extracellular fluid losses
Lactated Ringer's (Hartmann's) solution	Isotonic	274	0	• Similar in composition to normal plasma except does not contain Mg^{2+} • Used to treat losses from burns and lower GI • May be used to treat mild metabolic acidosis but should not be used to treat lactic acidosis • Does not provide free water or calories

contains sodium, potassium, chloride, calcium, and lactate (the precursor of bicarbonate) in about the same concentrations as those of ECF. It is contraindicated in patients with hyperkalemia and lactic acidosis because they have a decreased ability to convert lactate to bicarbonate.

Isotonic saline (0.9% NaCl) has a sodium concentration (154 mEq/L) somewhat higher than that of plasma (135 to 145 mEq/L) and a chloride concentration (154 mEq/L) significantly higher than the plasma chloride level (96 to 106 mEq/L). Thus excessive administration of isotonic saline can result in elevated sodium and chloride levels. Isotonic saline may be used when a patient has experienced both fluid and sodium losses or as vascular fluid replacement in hypovolemic shock.

Hypertonic. A hypertonic solution initially raises the osmolality of ECF and expands it. In addition, the higher osmotic pressure draws water out of the cells into ECF. It is useful in the treatment of hypovolemia and hyponatremia. Table 17-17 lists commonly used hypertonic solutions. Hypertonic solutions require frequent monitoring of blood pressure, lung sounds, and serum sodium levels because of the risk for intravascular fluid volume excess.[15]

Although concentrated dextrose and water solutions (10% dextrose or greater) are hypertonic solutions, once the dextrose is metabolized, the net result is the administration of water. The free water provided by these solutions ultimately expands both ECF and ICF. The primary use of these solutions is the provision of calories as part of parenteral nutrition. Parenteral nutrition is composed of concentrated dextrose solutions with amino acids, electrolytes, vitamins, and trace elements (see Chapter 40). You may administer solutions containing 10% dextrose or less through a peripheral line. However, you must use a central line to administer solutions with concentrations greater than 10% dextrose. (Central lines are discussed at right.)

Intravenous Additives. In addition to the basic solutions that provide water, electrolytes, and a minimum amount of calories, there are additives to replace specific losses. KCl, CaCl, $MgSO_4$, and HCO_3^- are common additives to the basic IV solutions. The use of these additives is mentioned previously in the discussion of the specific electrolyte deficiencies.

Plasma Expanders. Plasma expanders stay in the vascular space and increase the osmotic pressure. Plasma expanders include colloids, dextran, and hetastarch (Hespan). Colloids are protein solutions such as plasma, albumin, and commercial plasmas (e.g., Plasmanate). Albumin is available in 5% and 25% solutions. The 5% solution has an albumin concentration similar to that of plasma and results in plasma volume expansion equal to the volume infused. This makes the 5% concentration useful in treating hypovolemic patients. In contrast, 25% albumin solution is hypertonic and draws additional fluid from the interstitial space. The main use of the 25% concentration is as a volume expander following a paracentesis for ascites.[16] Dextran is a complex synthetic sugar. Because dextran metabolizes slowly, it remains in the vascular system for a prolonged period (but not as long as the colloids). It pulls additional fluid into the intravascular space. Hetastarch is a synthetic colloid that works similarly to dextran to expand plasma volume. (See Chapter 67 for a discussion of plasma volume expanders.)

If the patient has lost blood, whole blood or packed RBCs are necessary. Packed RBCs have the advantage of giving the patient primarily RBCs. Thus the blood bank can use the plasma for blood components. Although packed RBCs have a decreased plasma volume, they increase the oncotic pressure and pull fluid into the intravascular space. The use of whole blood, with its additional fluid volume, may cause circulatory overload, particularly in patients who are susceptible to complications from excess circulating volume (e.g., heart failure). To prevent manifestations of fluid volume excess, loop diuretics may be administered with blood. (See Chapter 31 for more information on the administration of blood and blood products.)

DELEGATION DECISIONS

Intravenous Therapy

Although many states permit licensed practical nurses (LPNs) to administer IV fluids and medications, administration of IV fluids or medications to unstable or critically ill patients should be done by the registered nurse (RN).

Role of Registered Nurse (RN)

- Assess patient for clinical manifestations of fluid and electrolyte disturbances.
- Determine whether ordered IV therapies are still appropriate based on monitoring of patient hydration and electrolyte levels.
- Choose and insert appropriate IV catheters and infusion devices.
- Administer IV fluids and medications to unstable and critically ill patients.
- Evaluate patient for clinical manifestations of fluid overload or hypovolemia and initiate appropriate changes in IV fluids.
- Evaluate whether patient fluid and electrolyte needs are being addressed with IV therapies.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Administer IV fluids and medications to stable patients (consider state nurse practice act and agency policy).
- Adjust IV flow rate for stable patients according to health care provider orders (consider state nurse practice act and agency policy).
- Insert IV catheters (consider state nurse practice act and agency policy).
- Monitor for clinical manifestations of adverse reactions to IV fluids or medications.

Role of Unlicensed Assistive Personnel (UAP)

- Measure and record oral intake and output.
- Report swelling or redness at IV site or patient complaints of discomfort at IV site to RN.

CENTRAL VENOUS ACCESS DEVICES

Central venous access devices (CVADs) are catheters placed in large blood vessels (e.g., subclavian vein, jugular vein) of people who require frequent or special access to the vascular system. There are three main types of CVADs: centrally inserted catheters, peripherally inserted central catheters (PICCs), and implanted ports. A physician may place any of these devices; a nurse with specialized training can insert PICCs.

Advantages of CVADs include immediate access to the central venous system, a reduced need for multiple venipunctures, and decreased risk of extravasation injury. CVADs permit frequent, continuous, rapid, or intermittent administration of fluids and medications. They allow for the administration of drugs that are potential vesicants, blood and blood products, and parenteral nutrition. CVADs can provide a means to perform hemodynamic monitoring and obtain venous blood samples. They are useful with patients who have limited peripheral vascular access or who have a projected need for long-term vascular access. Table 17-18 provides examples of conditions where CVADs are used.

TABLE 17-18 INDICATIONS FOR CENTRAL VENOUS ACCESS DEVICE (CVAD)*

Medical Condition	Indications for Use
Medication administration	
• Cancer	• Chemotherapy, infusion of irritating or vesicant medications
• Infection	• Long-term administration of antibiotics
• Pain	• Long-term administration of pain medication
• Drugs at risk for causing phlebitis	• epoprostenol (Flolan) • calcium chloride • potassium chloride • amiodarone (Cordarone)
Nutritional replacement	• Infusion of parenteral nutrition • Able to infuse higher dextrose solutions through CVAD than peripheral line
Blood samples	• Multiple blood draws for diagnostic tests over time
Blood transfusions	• Infusion of blood or blood products
Renal failure	• Perform hemodialysis (especially on an acute basis) or continuous renal replacement therapy
Shock, burns	• Infusion of high volumes of fluid and electrolyte replacement
Hemodynamic monitoring	• Used to measure central venous pressure to assess fluid balance
Heart failure	• Perform ultrafiltration
Autoimmune disorders	• Perform plasmapheresis

*This list is not all-inclusive, and these are examples only.

Specifically indicated CVADs are safe for injections of radiopaque contrast media at high pressures and controlled rates. For patients who already have poor peripheral venous access, using the port to inject contrast media decreases discomfort from venipuncture and helps lower the risk for extravasation of vesicant contrast media.[17]

The major disadvantages of CVADs are an increased risk of systemic infection and the invasiveness of the procedure. Extravasation can still occur if there is displacement of or damage to the device.

Centrally Inserted Catheters

Centrally inserted catheters (also called central venous catheters [CVCs]) are inserted into a vein in the neck or chest (subclavian or jugular) or groin (femoral) with the tip resting in the distal end of the superior vena cava (Fig. 17-18). The other end of the catheter is either nontunneled or tunneled through subcutaneous tissue and exits through a separate incision on the chest or abdominal wall. A Dacron cuff serves to stabilize the catheter and may decrease the incidence of infection by impeding bacteria migration along the catheter beyond the cuff. Do not use a newly place CVAD until the tip position is verified with a chest x-ray.

These catheters are single-, double-, triple-, or quad-lumen catheters. Multi-lumen catheters are useful in the critically ill patient because all of the lumens can provide a different therapy simultaneously. For example, incompatible drugs infuse in separate lumens without mixing while a third lumen provides access for blood sampling. Specific types of long-term central

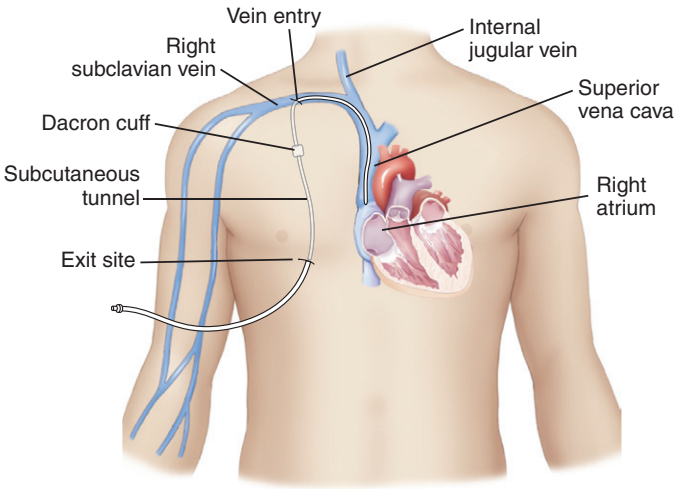

FIG. 17-18 Tunneled central venous catheter. Note tip of the catheter in the superior vena cava.

catheters are Hickman catheters, which require clamps to make sure the valve is closed, and Groshong catheters, which have a valve that opens as fluid is withdrawn or infused and remains closed when not in use.

Peripherally Inserted Central Catheters

PICCs are central venous catheters inserted into a vein in the arm rather than a vein in the neck or chest. They are inserted at or just above the antecubital fossa (usually cephalic or basilic vein) and advanced to a position with the tip ending in the distal one third of the superior vena cava. PICCs are single- or multiple-lumen, are nontunneled, and are up to 60 cm in length with gauges ranging from 24 to 16 (Fig. 17-19). They are used with patients who need vascular access for 1 week to 6 months but can be in place for longer periods.

Advantages of the PICC over a central venous catheter are lower infection rate, fewer insertion-related complications, decreased cost, and insertion at the bedside or outpatient area. Complications of PICCs include catheter occlusion and phlebitis (Table 17-19). If phlebitis occurs, it usually appears within 7 to 10 days after insertion. Do not use the arm with the PICC to obtain a blood pressure reading or draw blood.

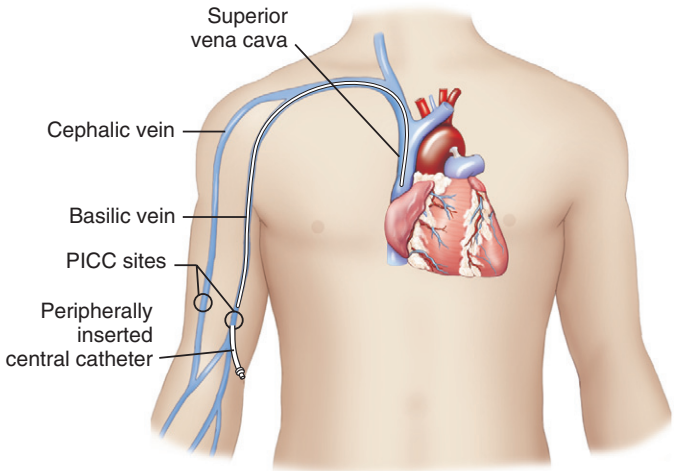

FIG. 17-19 Peripherally inserted central catheter *(PICC)* can be inserted using the basilic or cephalic vein.

TABLE 17-19 COMPLICATIONS OF CENTRAL VENOUS ACCESS DEVICES (CVADs)

Possible Cause	Clinical Manifestations	Management
Catheter Occlusion		
• Clamped or kinked catheter • Tip against wall of vessel • Thrombosis • Precipitate buildup in lumen	• Sluggish infusion or aspiration • Inability to infuse and/or aspirate	• Instruct patient to change position, raise arm, and cough. • Assess for and alleviate clamping or kinking. • Flush with normal saline using a 10-mL syringe. Do not force flush. • Perform fluoroscopy to determine cause and site. • Administer anticoagulant or thrombolytic agents.
Embolism		
• Catheter breaking • Dislodgment of thrombus • Entry of air into circulation	• Chest pain • Respiratory distress (dyspnea, tachypnea, hypoxia, cyanosis) • Hypotension • Tachycardia	• Administer O_2. • Clamp catheter. • Place patient on left side with head down (air emboli). • Notify physician.
Catheter-Related Infection (local or systemic)		
• Contamination during insertion or use • Migration of organisms along catheter • Immunosuppressed patient	• *Local:* redness, tenderness, purulent drainage, warmth, edema • *Systemic:* fever, chills, malaise	***Local*** • Culture drainage from site. • Apply warm, moist compresses. • Remove catheter if indicated. ***Systemic*** • Take blood cultures. • Give antibiotic therapy. • Give antipyretic therapy. • Remove catheter if indicated.
Pneumothorax		
• Perforation of visceral pleura during insertion	• Decreased or absent breath sounds • Respiratory distress (cyanosis, dyspnea, tachypnea) • Chest pain • Distended unilateral chest	• Administer O_2. • Position in semi-Fowler's position. • Prepare for chest tube insertion.
Catheter Migration		
• Improper suturing • Insertion site trauma • Changes in intrathoracic pressure • Forceful catheter flushing • Spontaneous	• Sluggish infusion or aspiration • Edema of chest or neck during infusion • Patient complaint of gurgling sound in ear • Dysrhythmias • Increased external catheter length	• Perform fluoroscopy to verify position. • Assist with removal and new CVAD placement.

Implanted Infusion Ports

Implanted infusion ports consist of a central venous catheter connected to an implanted, single or double subcutaneous injection port (Fig. 17-20, *A*). The catheter tip lies in the desired vein, and the other end is connected to a port that is surgically implanted in a subcutaneous pocket on the chest wall. The port consists of a metal sheath with a self-sealing silicone septum. To access these devices, a special Huber-point needle with a deflected tip is used to prevent damage to the rubber septum that could make the port useless (Fig. 17-20, *B*). Huber-point needles are also available with the tip at a 90-degree angle for longer infusions.

Drugs are placed in the port's reservoir either by a direct injection or through injection into an established IV line. After being filled, the reservoir slowly releases the medicine into the bloodstream. Implanted ports are good for long-term therapy and have a low risk of infection. The hidden port offers the patient cosmetic advantages and overall has less maintenance than other types of CVADs. Regular flushing is required to avoid the formation of "sludge" (clotted blood and drug precipitate) within the port septum.

Complications

CVADs always have a potential for complications. Astute monitoring and assessment may assist in early identification of potential complications. Table 17-19 lists common possible complications, potential causes, clinical manifestations, and interventions.

NURSING MANAGEMENT CENTRAL VENOUS ACCESS DEVICES

Nursing management of CVADs includes assessment, dressing changes and cleansing, injection cap changes, and maintenance of catheter patency. The exact frequency and procedures for these requirements vary by type of CVAD and institution, so it is important to follow your specific institution's policies and procedures. The following section discusses some general guidelines.

Catheter and insertion site assessment includes inspection of the site for redness, edema, warmth, drainage, and tenderness or pain. Observation of the catheter for misplacement or slippage is important. Perform a comprehensive pain assessment,

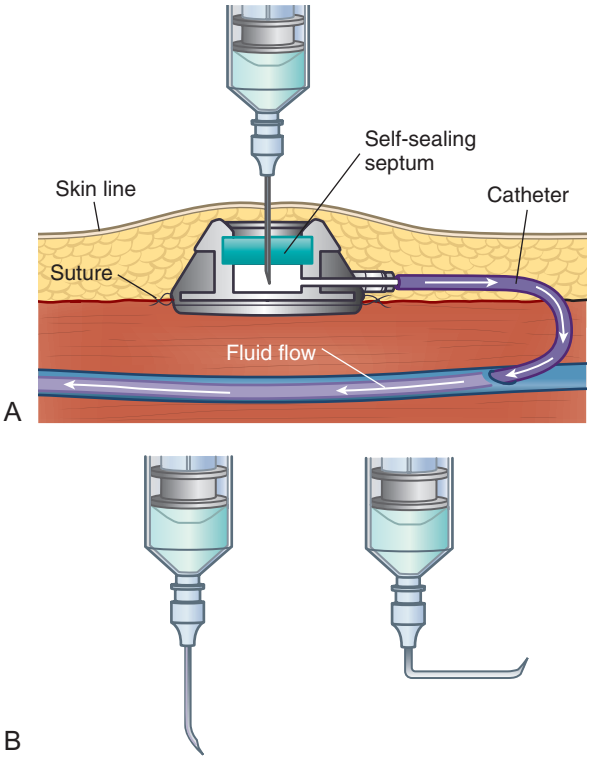

FIG. 17-20 **A,** Cross section of implantable port displaying access of the port with the Huber-point needle. Note the deflected point of the Huber-point needle, which prevents coring of the port's septum. **B,** Two Huber-point needles used to enter the implanted port. The 90-degree needle is used for top-entry ports for continuous infusion.

particularly noting any complaints of chest or neck discomfort, arm pain, or pain at the insertion site.[17] Before manipulating a catheter for any reason, perform hand hygiene.

Perform dressing changes and cleanse the catheter insertion site using strict sterile technique. Typical dressings include transparent semipermeable dressings or gauze and tape. If the site is bleeding, a gauze dressing may be preferable. Otherwise, transparent dressings are preferred. They allow observation of the site without having to remove the dressing. Transparent dressings may be left in place for up to 1 week if clean, dry, and intact. Change any dressing immediately if it becomes damp, loose, or visibly soiled.

Cleanse the skin around the catheter insertion site according to institution policy. A chlorhexidine-based preparation is the cleansing agent of choice. Its effects last longer than either povidone-iodine or isopropyl alcohol, offering improved killing of bacteria. When using chlorhexidine, cleansing the skin with friction is critical to infection prevention. When applying a new dressing, allow the area to air dry completely before application for chlorhexidine to be effective.[18] Secure the lumen ports to the skin above the dressing site. Document the date and time of the dressing change and initial the dressing.

Change injection caps at regular intervals according to institution policy or if they are damaged from excessive punctures. Use strict sterile technique. Teach the patient to turn the head to the opposite side of the CVAD insertion site during cap change. If the catheter cannot be clamped, instruct the patient to lie flat in bed and perform the Valsalva maneuver whenever the catheter is open to air to prevent an air embolism.

Flushing is one of the most effective ways to maintain lumen patency and to prevent occlusion of the CVAD.[19] It also keeps incompatible drugs or fluids from mixing. Use a normal saline solution in a syringe that has a barrel capacity of 10 mL or more to avoid excess pressure on the catheter. If you feel resistance, do not apply force. This could result in a ruptured catheter or create an embolism if a thrombus is present. Because of the risk of contamination and infection, prefilled syringes or single-dose vials are preferred over multiple-dose vials. If you are not using a positive-pressure valve cap, clamp any unused lines after flushing.

Use the push-pause technique when flushing all catheters. Push-pause creates turbulence within the catheter lumen, promoting the removal of debris that adheres to the catheter lumen and decreasing the chance of occlusion. This technique involves injecting saline with a rapid alternating push-pause motion, instilling 1 to 2 mL with each push on the syringe plunger. If you are using a negative-pressure cap or neutral pressure cap, clamp the catheter while maintaining positive pressure while instilling the last 1mL of saline in order to prevent reflux of blood back into the catheter. If a positive-pressure valve cap is present, it works to prevent the reflux of blood and resultant catheter lumen occlusion. Remove the syringe before clamping the catheter to allow the positive pressure valve to work correctly. Clamping the catheter during flushing with this cap may actually promote blood reflux.[19]

REMOVAL OF CVADs

Removal of CVADs is done according to institution policy and the nurse's scope of practice. In many agencies, nurses with demonstrated competency can remove PICCs and nontunneled central venous catheters. The procedure involves removing any sutures and then gently withdrawing the catheter. Instruct the patient to perform the Valsalva maneuver as the last 5 to 10 cm of the catheter is withdrawn. Immediately apply pressure to the site with sterile gauze to prevent air from entering and to control bleeding. Inspect the catheter tip to determine that it is intact. After bleeding has stopped, apply an antiseptic ointment and sterile dressing to the site.

CASE STUDY

Fluid and Electrolyte Imbalance

iStockphoto/Thinkstock

Patient Profile

S.S., a 63-year-old white woman with lung cancer, has been receiving chemotherapy on an outpatient basis. She completed her third treatment 5 days ago and has been experiencing nausea and vomiting for 2 days even though she has been using ondansetron (Zofran). S.S.'s daughter brings her to the hospital, where she is admitted to the medical unit. As the admitting nurse, you perform a thorough assessment.

Subjective Data

- Complains of lethargy, weakness, dizziness, and dry mouth
- States she has been too nauseated to eat or drink anything for 2 days

Objective Data

- Heart rate 110 beats/min, pulse thready
- BP 100/65
- Weight loss of 5 lb since she received her chemotherapy treatment 5 days ago
- Dry oral mucous membranes

Discussion Questions

1. Based on her clinical manifestations, what fluid imbalance does S.S. have?
2. What additional assessment data should you obtain?
3. What are her risk factors for fluid and electrolyte imbalances?
4. You draw blood for a serum chemistry evaluation. What electrolyte imbalances are likely and why?
5. S.S. is at risk for which acid-base imbalance? Describe the changes that would occur in S.S.'s ABGs with this acid-base imbalance. How would the body compensate?
6. The physician orders dextrose 5% in 0.45% saline to infuse at 100 mL/hr. What type of solution is this, and how will it help S.S.'s fluid imbalance?
7. ***Priority Decision:*** What are the priority nursing interventions for S.S.?
8. ***Evidence-Based Practice:*** S.S. has a double-lumen PICC in her left arm. One lumen is connected to the IV infusion; the other is unused. What is the recommended practice for maintaining the patency of the unused lumen?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. During the postoperative care of a 76-year-old patient, the nurse monitors the patient's intake and output carefully, knowing that the patient is at risk for fluid and electrolyte imbalances primarily because
- **a.** older adults have an impaired thirst mechanism and need reminding to drink fluids.
- **b.** water accounts for a greater percentage of body weight in the older adult than in younger adults.
- **c.** older adults are more likely than younger adults to lose extracellular fluid during surgical procedures.
- **d.** small losses of fluid are more significant because body fluids account for only about 50% of body weight in older adults.

2. During administration of a hypertonic IV solution, the mechanism involved in equalizing the fluid concentration between ECF and the cells is
- **a.** osmosis.
- **b.** diffusion.
- **c.** active transport.
- **d.** facilitated diffusion.

3a. An older woman was admitted to the medical unit with dehydration. Clinical indications of this problem are *(select all that apply)*
- **a.** weight loss.
- **b.** dry oral mucosa.
- **c.** full bounding pulse.
- **d.** engorged neck veins.
- **e.** decreased central venous pressure.

3b. The nursing care for a patient with hyponatremia includes
- **a.** fluid restriction.
- **b.** administration of hypotonic IV fluids.
- **c.** administration of a cation-exchange resin.
- **d.** increased water intake for patients on nasogastric suction.

3c. The nurse should be alert for which manifestations in a patient receiving a loop diuretic?
- **a.** Restlessness and agitation
- **b.** Paresthesias and irritability
- **c.** Weak, irregular pulse and poor muscle tone
- **d.** Increased blood pressure and muscle spasms

3d. Which patient would be at greatest risk for the potential development of hypermagnesemia?
- **a.** 83-year-old man with lung cancer and hypertension
- **b.** 65-year-old woman with hypertension taking β-adrenergic blockers
- **c.** 42-year-old woman with systemic lupus erythematosus and renal failure
- **d.** 50-year-old man with benign prostatic hyperplasia and a urinary tract infection

3e. It is especially important for the nurse to assess for which clinical manifestation(s) in a patient who has just undergone a total thyroidectomy *(select all that apply)*?
- **a.** Confusion
- **b.** Weight gain
- **c.** Depressed reflexes
- **d.** Circumoral numbness
- **e.** Positive Chvostek's sign

3f. The nurse anticipates that treatment of the patient with hyperphosphatemia secondary to renal failure will include
- **a.** fluid restriction.
- **b.** calcium supplements.
- **c.** loop diuretic therapy.
- **d.** magnesium supplements.

4. The lungs act as an acid-base buffer by
   a. increasing respiratory rate and depth when CO_2 levels in the blood are high, reducing acid load.
   b. increasing respiratory rate and depth when CO_2 levels in the blood are low, reducing base load.
   c. decreasing respiratory rate and depth when CO_2 levels in the blood are high, reducing acid load.
   d. decreasing respiratory rate and depth when CO_2 levels in the blood are low, increasing acid load.
5. A patient has the following arterial blood gas results: pH 7.52; $PaCO_2$ 30 mm Hg; HCO_3^- 24 mEq/L. The nurse determines that these results indicate
   a. metabolic acidosis.
   b. metabolic alkalosis.
   c. respiratory acidosis.
   d. respiratory alkalosis.
6. The typical fluid replacement for the patient with a fluid volume deficit is
   a. dextran.
   b. 0.45% saline.
   c. lactated Ringer's.
   d. 5% dextrose in 0.45% saline.
7. The nurse is unable to flush a central venous access device and suspects occlusion. The best nursing intervention would be to
   a. apply warm moist compresses to the insertion site.
   b. attempt to force 10 mL of normal saline into the device.
   c. place the patient on the left side with head-down position.
   d. instruct the patient to change positions, raise arm, and cough.

1. d, 2. a, 3a. a, b, e, 3b. a, 3c. c, 3d. c, 3e. a, d, e, 3f. b, 4. a, 5. d, 6. c, 7. d

CASE STUDY

Managing Multiple Patients

You are assigned to care for the following three patients in the intensive care unit (ICU). There are two other RNs and two unlicensed assistive personnel (UAP) on duty to care for a total of 12 patients currently in the unit.

Patients

iStockphoto/Thinkstock

G.N., a 58-year-old African American man, was admitted to the ICU after falling out of a tree onto a lit gas grill. He has partial-thickness burns on his face, neck, and upper trunk. He has undergone surgical repair of right tibia and left hip fractures as well as debridement of a severely lacerated right leg. His voice is slightly hoarse and he is coughing up sooty sputum. He is receiving O_2 at 4 L/min via nasal cannula and his O_2 saturation is 93%. His WBC count is 26,400/μL (26.4×10^9/L) with 80% neutrophils (10% bands).

iStockphoto/Thinkstock

J.N., a 35-year-old African American woman, was transferred to the ICU from the clinical unit last evening with acute respiratory failure. She was diagnosed 2 days ago with AIDS and *Pneumocystis jiroveci* pneumonia (PCP). Prior to this hospital admission she had consistently refused antiretroviral therapy (ART) because she could not afford it. She was started on oral trimethoprim/sulfamethoxazole (Bactrim) and combination antiretroviral therapy. However, her respiratory distress worsened and she was transferred to the ICU for intubation and mechanical ventilation. She is started on IV Bactrim and corticosteroid therapy.

iStockphoto/Thinkstock

S.S., a 63-year-old white woman with lung cancer, has been receiving chemotherapy on an outpatient basis. She completed her third treatment 5 days ago and has been experiencing nausea and vomiting for 2 days even though she has been using ondansetron (Zofran). She was initially admitted to the medical unit but was transferred to the ICU for closer monitoring after becoming severely hypotensive overnight. Her most recent blood pressure was 98/50.

Management Discussion Questions

1. ***Priority Decision:*** After receiving report, which patient should you see first? Provide rationale.
2. ***Delegation Decision:*** Which of the following morning tasks should you delegate to the UAP *(select all that apply)?*
   a. Take blood pressure readings on S.S.
   b. Perform neurovascular checks on G.N.
   c. Document strict intake and output on S.S.
   d. Provide oral care around the endotracheal tube for J.N.
   e. Titrate S.S.'s IV infusion rate based on her blood pressure reading.
3. ***Priority and Delegation Decision:*** When you enter J.N.'s room, the ventilator alarms are going off. The UAP had just finished providing oral care and she tells you that J.N. has become increasingly agitated within the last 5 minutes. Which initial action would be most appropriate?
   a. Suction J.N.'s endotracheal tube.
   b. Have the UAP stay with J.N. while you obtain IV sedation for her.
   c. Ask the UAP to describe exactly what she did when she was performing oral care.
   d. Assess the ventilator to identify what alarm is going off and to make sure all connections are secure.

Case Study Progression

J.N.'s ventilator tubing had become disconnected. You quickly reconnect her tubing and she settles down as her oxygenation improves. You ask the UAP to obtain vital signs on all your patients while you begin a more thorough assessment of J.N.

4. During your assessment of J.N., you note grey-white patches on the inside of her mouth. You recognize these as most likely caused by
   a. *Candida albicans.*
   b. poor oral hygiene.
   c. *Coccidioides immitis.*
   d. irritation from recent mouth care.
5. G.N.'s family asks you why surgery was performed on his leg wound. Your response is based on the knowledge that debridement *(select all that apply)*
   a. is used to remove infected tissue.
   b. is used to remove nonviable tissue.
   c. prepares the wound bed for healing.
   d. can only be accomplished with surgery.
6. S.S.'s morning laboratory results reveal a serum potassium level of 2.8 mEq/L. You notify the health care provider and obtain an order for IV potassium. During infusion of the potassium aliquots, you prioritize assessment of S.S.'s
   a. bowel function.
   b. cardiac rhythm.
   c. muscle strength.
   d. level of consciousness.
7. ***Management Decision:*** While sitting at the computer charting your patients' morning assessments, you overhear the UAP telling a nursing student that J.N. deserves what she got because HIV is God's way of punishing those who sin. Your most appropriate response would be to
   a. report the UAP's actions to your supervisor.
   b. ask the UAP to keep her opinions to herself.
   c. ignore the conversation as it does not impact patient care.
   d. talk to the UAP and student about keeping personal feelings separate from patient care.

LEARNING OUTCOMES

1. Differentiate the common purposes and settings of surgery.
2. Apply knowledge of the purpose and components of a preoperative nursing assessment.
3. Interpret the significance of data related to the preoperative patient's health status and operative risk.
4. Analyze the components and purpose of informed consent for surgery.
5. Examine the nursing role in the physical, psychologic, and educational preparation of the surgical patient.
6. Prioritize the nursing responsibilities related to day-of-surgery preparation for the surgical patient.
7. Differentiate the purposes and types of common preoperative medications.
8. Apply knowledge of the special considerations of preoperative preparation for the older adult surgical patient.

KEY TERMS

ambulatory surgery, p. 318
elective surgery, p. 318
emergency surgery, p. 318
informed consent, p. 325
same-day admission, p. 318
surgery, p. 317

Preparation of patients for surgery is an important nursing role. This chapter includes a discussion of preoperative care that is applicable to all surgical patients regardless of where the surgery is performed. Preparation measures for specific surgical procedures (e.g., abdominal, thoracic, or orthopedic surgery) are discussed in appropriate chapters of this text.

Surgery is the art and science of treating diseases, injuries, and deformities by operation and instrumentation. The surgical experience involves a multidisciplinary interaction among the patient, surgeon, anesthesia care provider (ACP), nurse, and other health care team members as needed. Surgery may be performed for any of the following purposes:

- *Diagnosis:* Determination of the presence and extent of a pathologic condition (e.g., lymph node biopsy, bronchoscopy).
- *Cure:* Elimination or repair of a pathologic condition (e.g., removal of ruptured appendix or benign ovarian cyst).
- *Palliation:* Alleviation of symptoms without cure (e.g., cutting a nerve root [rhizotomy] to remove symptoms of pain, creating a colostomy to bypass an inoperable bowel obstruction).
- *Prevention* (e.g., removal of a mole before it becomes malignant, removal of the colon in a patient with familial polyposis to prevent cancer).
- *Cosmetic improvement* (e.g., repairing a burn scar, breast reconstruction after a mastectomy).
- *Exploration:* Surgical examination to determine the nature or extent of a disease (e.g., laparotomy). With the advent of advanced diagnostic tests, exploration is less common because problems can be identified earlier and easier.

TABLE 18-1 SUFFIXES DESCRIBING SURGICAL PROCEDURES

Suffix	Meaning	Example
-ectomy	Excision or removal of	Appendectomy
-lysis	Destruction of	Electrolysis
-orrhaphy	Repair or suture of	Herniorrhaphy
-oscopy	Looking into	Endoscopy
-ostomy	Creation of opening into	Colostomy
-otomy	Cutting into or incision of	Tracheotomy
-plasty	Repair or reconstruction of	Mammoplasty

Specific suffixes are commonly used in combination with a body part or organ in naming surgical procedures (Table 18-1).

SURGICAL SETTINGS

Surgery may be a carefully planned event **(elective surgery)** or may arise with unexpected urgency **(emergency surgery).** Both elective and emergency surgery may be performed in a variety of settings. The setting in which a surgical procedure may be safely and effectively performed is influenced by the type of surgery, potential complications, and the patient's general health status.

For inpatient surgery, patients who are going to be admitted to the hospital are usually admitted on the day of surgery **(same-day admission).** Patients who are in the hospital before surgery are usually there because of acute or chronic medical conditions.

The majority of surgical procedures are performed as **ambulatory surgery** (also called *same-day* or *outpatient surgery*). Many of these surgeries use minimally invasive techniques (e.g., laparoscopic techniques). (The surgeries are described in chapters throughout the text in discussions of interventions for specific problems.) Ambulatory surgery may be conducted in endoscopy clinics, physicians' offices, freestanding surgical clinics, and outpatient surgery units in hospitals. These procedures can be performed using general, regional, or local anesthetic; have an operating time of less than 2 hours; and require less than a 24-hour stay postoperatively. Many patients go home with a caregiver within hours of surgery.

Ambulatory surgery is often preferred by patients and physicians. Generally, it involves minimal laboratory tests, requires fewer preoperative and postoperative medications, and reduces the patient's risk for health care–associated infections. Patients like the convenience of recovering at home, physicians prefer the flexibility in scheduling, and the cost is usually less for both the patient and the insurer.

Regardless of where the surgery is performed, you play an essential role in preparing the patient for surgery, caring for the patient during surgery, and facilitating the patient's recovery after surgery. To perform these functions effectively, first know the nature of the disorder requiring surgery and any coexisting medical problems. Second, identify the individual patient's response to the stress of surgery. Third, know the results of appropriate preoperative diagnostic tests. Finally, identify potential risks and complications associated with the surgical procedure and any coexisting medical problems that should be included in the plan of care. The nurse caring for the patient preoperatively is likely to be different from the nurse in the operating room (OR), postanesthesia care unit (PACU), surgical intensive care unit (SICU), or surgical unit. Thus communication and documentation of important preoperative assessment findings are essential for the continuity of care.

PATIENT INTERVIEW

One of the most important nursing actions is the preoperative interview. The nurse who works in the physician's office, the ambulatory surgery center, or the hospital preoperative area may do the interview. The site of the interview and the time before surgery dictate the depth and completeness of the interview. Important findings must be documented and communicated to others to maintain continuity of care.

The preoperative interview can occur in advance or on the day of surgery. The primary purposes of the patient interview are to (1) obtain the patient's health information; (2) provide and clarify information about the planned surgery, including anesthesia; and (3) assess the patient's emotional state and readiness for surgery, including his or her expectations about the surgical outcomes. Ensure that the patient's consent form for surgery has been signed and witnessed and that the appropriate laboratory and diagnostic tests have been ordered or completed.

The interview also provides the patient and the caregiver an opportunity to ask questions about surgery, anesthesia, and postoperative care. Often patients ask about taking their routine medications, such as insulin, anticoagulants, or cardiac medications, and if they will experience pain. By being aware of the patient's and caregiver's needs, you can provide the information and support needed during the perioperative period.

NURSING ASSESSMENT OF PREOPERATIVE PATIENT

The overall goal of the preoperative assessment is to identify risk factors and plan care to ensure patient safety throughout the surgical experience. Goals of the assessment are to

- Determine the patient's psychologic status in order to reinforce the use of coping strategies during the surgical experience.
- Determine physiologic factors directly or indirectly related to the surgical procedure that may contribute to operative risk factors.
- Establish baseline data for comparison in the intraoperative and postoperative period.
- Participate in the identification and documentation of the surgical site and/or side (of body) on which the surgical procedure will be performed.
- Identify prescription drugs, over-the-counter medications, and herbal supplements taken by the patient that may result in drug interactions affecting the surgical outcome.
- Document the results of all preoperative laboratory and diagnostic tests in the patient's record, and communicate this information to appropriate health care providers.
- Identify cultural and ethnic factors that may affect the surgical experience.
- Determine if the patient has received adequate information from the surgeon to make an informed decision to have surgery and that the consent form is signed and witnessed.

Subjective Data

Psychosocial Assessment. Surgery is a stressful event, even when the procedure is considered minor. The psychologic and physiologic reactions to surgery and anesthesia may elicit the stress response (e.g., elevated blood pressure [BP] and heart rate). The stress response enables the body to prepare to meet the demands in the perioperative period. If stressors or the responses to the stressors are excessive, the stress response can be magnified and may affect recovery. Many factors influence the patient's susceptibility to stress, including age, past experiences with illness and pain, current health, and socioeconomic status. Identifying a patient's perceived or actual stressors allows you to provide support during the preoperative period so that stress does not become distress.

The use of common language and avoidance of medical jargon are essential. Use words and language that are familiar to the patient to increase the patient's understanding of surgical consent and the surgery. Familiar language also helps reduce preoperative anxiety.

Your role in psychologically preparing the patient for surgery is to assess the patient for potential stressors that could negatively affect surgery (Table 18-2). Communicate all concerns to the appropriate surgical team member, especially if the concern requires intervention later in the surgical experience. Because many patients are admitted directly into the preoperative area from their homes, you must be skilled in assessing important psychologic factors in a short time. The most common psychologic factors are anxiety, fear, and hope.

TABLE 18-2 PSYCHOSOCIAL ASSESSMENT OF PREOPERATIVE PATIENT

Situational Changes
- Identify support systems, including family, other caregivers, group and institutional structures, and religious and spiritual groups.
- Define current degree of personal control, decision making, and independence.
- Consider the impact of surgery and hospitalization and the possible effects on lifestyle.
- Determine the presence of hope and anticipation of positive results.

Concerns With the Unknown
- Identify specific areas and degree of anxiety and fears related to the surgery (e.g., pain).
- Identify expectations of surgery, changes in current health status, effects on daily living, and sexual activity (if appropriate).

Concerns With Body Image
- Identify current roles or relationships and view of self.
- Determine perceived or potential changes in roles or relationships and their impact on body image.

Past Experiences
- Review previous surgical experiences, hospitalizations, and treatments.
- Determine responses to those experiences (positive and negative).
- Identify current perceptions of surgical procedure in relation to the above and information from others (e.g., a friend's view of a personal surgical experience).

Knowledge Deficit
- Identify the amount and type of preoperative information the patient wants.
- Assess understanding of the surgical procedure, including preparation, care, interventions, preoperative activities, restrictions, and expected outcomes.
- Identify the accuracy of information the patient has received from others, including health care team, family, friends, and the media.

Anxiety. Most people are anxious when facing surgery because of the unknown. This is normal and is an inborn survival mechanism. However, if the anxiety level is high, cognition, decision making, and coping abilities are reduced.

Anxiety can arise from lack of knowledge, which may range from not knowing what to expect during surgery to uncertainty about the outcome. This may be a result of past experiences or stories heard through friends or the media. You can decrease some anxiety for the patient by providing information about what to expect. This is often done through classes, or web-based or audiovisual educational materials before surgery. Inform the surgeon if the patient requires any additional information or if anxiety is excessive.

The patient may experience anxiety when surgery is in conflict with his or her religious and cultural beliefs. In particular, identify, document, and communicate the patient's religious and cultural beliefs about the possibility of blood transfusions. For example, Jehovah's Witnesses may choose to refuse blood or blood products.[1]

Common Fears. Patients fear surgery for a number of reasons. The most common fear is the risk of death or permanent disability resulting from surgery. Sometimes the fear arises after hearing or reading about the risks during the informed consent process. Other fears are related to pain, change in body image, or results of diagnostic procedures.

Fear of death can be extremely harmful. Notify the physician if the patient has a strong fear of death. A patient's strong fear of impending death may prompt the physician to delay the surgery until the situation improves because the emotional state influences the stress response, and thus the surgical outcome.

Fear of pain and discomfort during and after surgery is common. If the fear is extreme, notify the ACP or the surgeon. Reassure the patient that drugs are available for both anesthesia and analgesia during surgery. For pain after surgery, tell patients to ask for pain medication before pain becomes severe. Instruct the patient on the use of a pain intensity scale (e.g., 0 to 10, FACES [see eFig. 9-3, available on the website for Chapter 9]). (Pain scales are explained in Chapter 9.)

Drugs may also be given that provide an amnesic effect so the patient will not remember what occurs during surgery. Tell the patient that this effect assists in decreasing anxiety after surgery.

Fear of mutilation or alteration in body image can occur whether the surgery is radical, such as amputation, or minor, such as a bunion repair. Even a small scar on the body can be upsetting to some, and others fear keloid development (overgrowth of a scar). Listen to and assess the patient's concern about this fear with an accepting attitude.

Fear of anesthesia may arise from the unknown, personal experience, or tales of others' bad experiences. These concerns can also result from information about the risks (e.g., brain damage, paralysis) of anesthesia. Many patients fear losing control while under anesthesia. If these fears are identified, inform the ACP immediately so that he or she can talk further with the patient. Reassure the patient that a nurse and the ACP will be present at all times during surgery.

Fear of disruption of life functioning may be present in varying degrees. It can range from fear of permanent disability to concern about not being able to engage in activities of daily

living for a few weeks. Concerns about loss of role function, separation from family, and how the family will manage may be revealed. Financial concerns may be related to an anticipated loss of income or the costs of surgery.

If you identify any of these fears, a consult with the patient's caregiver, a social worker, a spiritual or cultural advisor, or a psychologist may be appropriate. Financial advisors at the hospital may be able to provide information about financial support.

Hope. Although many psychologic factors related to surgery seem to be negative, hope is a positive attribute.[2] Hope may be the patient's strongest method of coping. To deny or minimize hope may negate the positive mental attitude necessary for a quick and full recovery. Some surgeries are hopefully anticipated. These can be the surgeries that repair (e.g., plastic surgery for burn scars), rebuild (e.g., total joint replacement to reduce pain and improve function), or save and extend life (e.g., repair of aneurysm, organ transplant). Assess and support the presence of hope and the patient's anticipation of positive results.

Past Health History. Ask the patient about any previous medical problems and surgeries. Determine if the patient understands the need for surgery. For example, the patient scheduled for a total knee replacement may indicate that increasing pain and immobility are the reasons for the surgery.

Document the reason for any past hospitalizations, including previous surgeries and the dates. Also identify any problems with previous surgeries. For example, the patient may have experienced a wound infection or a reaction to a medication.

Ask women about their menstrual and obstetric history. This includes the date of their last menstrual period, the number of pregnancies, and any history of cesarean section.

When obtaining a family health history, ask both patient and caregiver about any inherited traits, since they may contribute to the surgical outcome. Record any family history of cardiac and endocrine diseases. For example, if a patient reports a parent with hypertension, sudden cardiac death, or myocardial infarction, this should alert you to the possibility that the patient may have a similar predisposition or condition. Also obtain information about the patient's family history of adverse reactions to or problems with anesthesia. For example, malignant hyperthermia has a genetic predisposition. Measures to decrease complications associated with this condition can be taken. (For further information on malignant hyperthermia, see Chapter 19.)

Medications. Document all current routine and intermittent medication use, including over-the-counter drugs and herbal supplements. In many ambulatory surgery centers, patients are asked to bring their medications with them when reporting for surgery. This helps to accurately assess and document both the name and the dosage of medications.

The interaction of the patient's current medications and anesthetics can increase or decrease the desired physiologic effect of anesthetics. Consider the effects of opioids and prescribed medications for chronic health conditions (e.g., heart disease, hypertension, depression, epilepsy, diabetes mellitus). For example, certain antidepressants can potentiate the effect of opioids, agents that can be used for anesthesia. Antihypertensive drugs may predispose the patient to shock from the combined effect of the drug and the vasodilator effect of some anesthetic agents. Insulin or oral hypoglycemic agents may require dose or agent adjustments during the perioperative period because of increased body metabolism, decreased oral intake, stress, and anesthesia. Antiplatelet drugs (e.g., aspirin, clopidogrel [Plavix]) and nonsteroidal antiinflammatory drugs (NSAIDs) inhibit platelet aggregation and may contribute to postoperative bleeding. Surgeons may instruct patients to withhold these medications before surgery. Specific timeframes for withholding drugs depend on the drug and the patient. Patients on long-term anticoagulation therapy (e.g., warfarin [Coumadin]) present a unique challenge. The options for these patients include (1) continuing therapy, (2) withholding therapy for a time before and after surgery, or (3) withholding the therapy and starting subcutaneous or IV heparin therapy during the perioperative period. The management strategy selected is determined by patient characteristics and the nature of the surgery.[3]

Ask about the use of herbs and dietary supplements because their use is so common. Many patients do not think to include supplements in their list of medications. They believe that herbal and dietary supplements are "natural" and do not pose a surgical risk.[4] (See the Complementary & Alternative Therapies box in Chapter 3 on p. 39 on how to assess for the use of herbal supplements.) Excessive use of vitamins and herbs can cause harmful effects in patients undergoing surgery. In patients taking anticoagulants or antiplatelets, herbal supplements can produce excessive postoperative bleeding that may require a return to the OR.[5] The effects of specific herbs that are of concern during the perioperative period are listed below in the Complementary & Alternative Therapies box.

Also ask the patient about possible recreational drug use, abuse, and addiction. The substances most likely to be abused include tobacco, alcohol, opioids, marijuana, cocaine, and amphetamines. Ask questions about the use of these substances in a frank manner. Stress that recreational drug use may affect the type and amount of anesthesia that will be needed. When patients become aware of the potential interactions of these substances with anesthetics, most patients respond honestly about using them. Chronic alcohol use can place the patient at risk because of lung, gastrointestinal, or liver damage. When liver function is decreased, metabolism of anesthetic agents is prolonged, nutritional status is altered, and the potential for postoperative complications is increased. Alcohol withdrawal can also occur during lengthy surgery or in the postoperative period. Although this can be a life-threatening event, it can be

COMPLEMENTARY & ALTERNATIVE THERAPIES

Herbal Products and Surgery

The following can be used as a guide for patient teaching:

- Notify your health care provider of all vitamins, herbal products, and dietary supplements that you are or have been taking.
- Avoid astragalus and ginseng, since they can increase blood pressure before and during surgery.
- Avoid garlic, vitamin E, ginkgo, and fish oils because they can increase bleeding.
- Avoid kava and valerian because they can cause excess sedation.
- In general, discontinue all herbal supplements 2 to 3 weeks before any surgical procedure. Consult your health care provider for specific instructions.

Helpful Herbs and Vitamins

- Ginger can be useful for preventing nausea associated with anesthesia. Consider ginger ale, crystallized ginger, or ginger tea.
- Arnica is a homeopathic remedy useful in soft tissue healing.
- Multivitamins can be taken until the day before surgery. Taking them on the day of surgery, on an empty stomach, may contribute to nausea and vomiting after surgery.

avoided with appropriate planning and management (see Chapter 11).

Document and communicate all findings of the medication history to the perioperative health care team. The ACP will determine the appropriate schedule and dose of the patient's routine medications before and after surgery. Ensure that all of the patient's medications are identified, implement any changes in the medication plan, and monitor the patient for potential interactions and complications.

Allergies. Question the patient about drug intolerances and drug allergies. Drug intolerance usually results in side effects that are uncomfortable or unpleasant for the patient but are not life threatening. These effects can include nausea, constipation, diarrhea, or *idiosyncratic* (opposite than expected) reactions. A true drug allergy produces hives and/or an anaphylactic reaction, causing cardiopulmonary compromise (e.g., hypotension, tachycardia, bronchospasm). Being aware of drug intolerances and drug allergies aids the health care team to maintain patient comfort and safety. For example, some anesthetic agents contain sulfur, so notify the ACP if a history of allergy to sulfur is reported. Document all drug intolerances and drug allergies and, if appropriate, place an allergy identification band on the patient on the day of surgery.

Also inquire about nondrug allergies, specifically food and environmental (e.g., latex, pollen, animals) allergies. The patient with a history of any allergic reactions has a greater potential for hypersensitivity reactions to drugs given during anesthesia. Patients need to be screened specifically for latex allergies by gathering data in the following areas:

- Risk factors
- Contact dermatitis
- Contact urticaria (e.g., hives)
- Aerosol reactions
- History of reactions that suggest an allergy to latex

Risk factors for latex allergy include long-term, multiple exposures to latex products, such as those experienced by health care and rubber industry workers. Additional risk factors include a history of hay fever, asthma, and allergies to certain foods (e.g., eggs, avocados, bananas, chestnuts, potatoes, peaches).[6] (Latex allergies are discussed in Chapter 14.)

Review of Systems. The last component of the patient history is the body systems review. Ask specific questions to confirm the presence or absence of any diseases. Current medical problems can alert you to areas that should be more closely examined in the preoperative physical examination. The combined review of systems and the patient history provide essential data to determine the specific preoperative tests that need to be ordered.

Cardiovascular System. Evaluate cardiovascular (CV) function to determine preexisting disease or problems (e.g., coronary artery disease, prosthetic heart valve). In reviewing the CV system, you may find a history of hypertension, angina, dysrhythmias, heart failure, or myocardial infarction. Inquire about the patient's current treatment for any CV condition (e.g., medications) and the level of functioning. A cardiology consult is often required before surgery if the patient has a significant CV history (e.g., recent myocardial infarction, valvular heart disease, implantable cardioverter-defibrillator).

If indicated, a 12-lead electrocardiogram (ECG) and coagulation studies should be ordered, and the results should be on the chart before surgery. The CV assessment provides data on what other measures need to be done. For example, the patient who is on diuretic therapy will need to have a serum potassium level drawn preoperatively. If the patient has a history of hypertension, the ACP may administer vasoactive drugs to maintain adequate BP during surgery. If the patient has a history of valvular heart disease, antibiotic prophylaxis often is given before surgery to decrease the risk of bacterial endocarditis (see Chapter 37).

Postoperative venous thromboembolism (VTE), a condition that includes deep vein thrombosis and pulmonary embolism, is a concern for any surgical patient. Patients at high risk for VTE include those with a history of previous thrombosis, blood-clotting disorders, cancer, varicosities, obesity, smoking, heart failure, or chronic obstructive pulmonary disease (COPD).[7] People are also at risk for developing a VTE because of immobility and positioning during the operative procedure. Antiembolism stockings or sequential compression devices may be applied to the legs in the preoperative holding area.

Respiratory System. Ask the patient about any recent or chronic respiratory disease or infections. Elective surgery may need to be postponed if the person has an upper respiratory tract infection. Upper airway infections increase the risk of bronchospasm, laryngospasm, decreased O_2 saturation, and problems with respiratory secretions. Also report a patient's history of dyspnea at rest or with exertion, coughing (dry or productive), or hemoptysis (coughing blood) to the ACP and the surgeon.

If a patient has a history of asthma, inquire about the use of inhaled or oral corticosteroids and bronchodilators, as well as the frequency and triggers of asthma attacks. The patient with a history of COPD is at high risk for postoperative pulmonary complications, including hypoxemia and atelectasis.

Encourage the patient who smokes to stop at least 6 weeks preoperatively to decrease the risk of intraoperative and postoperative respiratory complications. The greater the patient's pack-years of smoking (packs smoked per day times years), the greater the risk for pulmonary complications during or after surgery. Report conditions likely to affect respiratory function such as sleep apnea; obesity; and spinal, chest, and airway deformities. For example, patients may be asked to bring their sleep apnea devices with them to the hospital or surgical center. Depending on the patient's history and physical examination, baseline pulmonary function tests and arterial blood gases may be ordered preoperatively.

Neurologic System. Preoperative evaluation of neurologic functioning includes assessing the patient's ability to respond to questions, follow commands, and maintain orderly thought patterns. Alterations in the patient's hearing and vision may affect responses and the ability to follow directions throughout the perioperative assessment and evaluation. Document the patient's ability to pay attention, concentrate, and respond appropriately to establish a preoperative baseline for postoperative comparison.

If you note deficits in cognitive function, determine the extent of the problems and whether they can be corrected before surgery. If the problems cannot be corrected, it is important to involve a legal guardian or person with durable power of attorney for health care to assist the patient and provide informed consent for surgery.

Preoperative assessment of the older person's baseline cognitive function is especially crucial for intraoperative and postoperative evaluation.[8] The older adult may have intact mental abilities preoperatively, but is more prone to adverse outcomes

during and after surgery than the younger adult. This is due to the additional stressors of the surgical procedure, dehydration, hypothermia, and anesthesia and adjunctive medications. These factors may contribute to the development of emergence delirium ("waking up wild"), a condition that may be falsely labeled as senility or dementia. Thus preoperative findings are critical for postoperative comparison.

In the review of the neurologic system, inquire about any history of strokes, transient ischemic attacks, or spinal cord injury. Also ask about neurologic diseases, such as myasthenia gravis, Parkinson's disease, and multiple sclerosis, and any treatments used.

Genitourinary System. Assess the preoperative patient for a history of renal or urinary tract diseases, such as glomerulonephritis, chronic kidney disease, or repeated urinary tract infections. Document the present disease state and treatment used to control the disease. Renal dysfunction is associated with a number of alterations, including fluid and electrolyte imbalances, coagulopathies, increased risk for infection, and impaired wound healing. Because many drugs are metabolized and excreted by the kidneys, a decrease in renal function can lead to an altered response to drugs and unpredictable drug elimination. Renal function tests, such as serum creatinine and blood urea nitrogen (BUN), are commonly ordered preoperatively.

Document and report to the perioperative team if the patient has problems voiding (e.g., incontinence, hesitancy). Male patients may have physical conditions, such as an enlarged prostate, that can interfere with the insertion of a urinary catheter during surgery or impair voiding in the postoperative period.

For women of childbearing age, determine if they are pregnant or think they could be pregnant. Most institutions require a pregnancy test for all women of childbearing age before surgery.[9] Immediately inform the surgeon if the patient states that she might be pregnant, since maternal and subsequent fetal exposure to anesthetics during the first trimester should be avoided.

Hepatic System. The liver is involved in glucose homeostasis, fat metabolism, protein synthesis, drug and hormone metabolism, and bilirubin formation and excretion. The liver detoxifies many anesthetics and adjunctive drugs. The patient with hepatic dysfunction may have an increased perioperative risk for clotting abnormalities and adverse responses to medications. Consider the presence of liver disease if there is a history of jaundice, hepatitis, alcohol abuse, or obesity.

Integumentary System. Inquire about a history of skin problems. Assess the current condition of the skin, especially at the incision site, for rashes, breakdown, or other dermatologic conditions. A patient with a history of pressure ulcers may require extra padding during surgery. Skin problems can affect postoperative healing.

Body art such as tattoos and piercings are increasingly common. When possible, select pigment-free areas for injections, IV sites, and laboratory draws.

Musculoskeletal System. Note any musculoskeletal and mobility problems, especially in the older adult. If the patient has arthritis, identify all affected joints. Mobility restrictions may influence intraoperative and postoperative positioning and ambulation. Spinal anesthesia may be difficult if the patient cannot flex his or her lumbar spine adequately to allow easy needle insertion. If the neck is affected, intubation and airway management may be difficult. Any mobility aids (e.g., cane, walker) should be brought with the patient on the day of surgery.

Endocrine System. The patient with diabetes is especially at risk for adverse effects of anesthesia and surgery. Hypoglycemia, hyperglycemia, delayed wound healing, and infection are common complications of diabetes during the perioperative period. Clarify with the patient's surgeon or ACP whether the patient should take the usual dose of insulin or oral hypoglycemic agents on the day of surgery. ACPs may vary the usual insulin dose based on the patient's current status and history of glucose control. Regardless of the preoperative insulin orders, determine serum or capillary glucose levels the morning of surgery to establish baseline levels. Assess the patient's glucose levels periodically and manage, if necessary, with short-acting or rapid-acting insulin.

Determine if the patient has a history of thyroid dysfunction. Hyperthyroidism or hypothyroidism can place the patient at surgical risk because of alterations in metabolic rate. If the patient takes a thyroid replacement drug, check with the ACP about administration of the drug on the day of surgery. If the patient has a history of thyroid dysfunction, laboratory tests may be ordered to determine current levels of thyroid function.

The patient with Addison's disease also requires special consideration during surgery. Addisonian crisis or shock can occur if a patient abruptly stops taking replacement corticosteroids, and the stress of surgery may require additional IV corticosteroid therapy[10] (see Chapter 50).

Immune System. If the patient has a history of a compromised immune system or takes immunosuppressive drugs, document it. Corticosteroids used in immunosuppressive doses may be tapered before surgery. Impairment of the immune system can lead to delayed wound healing and increased risk for postoperative infections.[11] If the patient has an acute infection (e.g., upper respiratory tract infection, sinusitis, influenza), elective surgery is often canceled. Patients with active chronic infections such as hepatitis B or C, acquired immunodeficiency syndrome, or tuberculosis may have surgery if indicated. However, when preparing the patient for surgery, remember to take infection control precautions for the protection of the patient and staff.[12] (Infection control guidelines are discussed in Chapter 15 and eTable 15-1, available on the website for Chapter 15.)

Fluid and Electrolyte Status. Ask the patient about any recent conditions that increase the risk for fluid and electrolyte imbalances, such as vomiting, diarrhea, or preoperative bowel preps. For example, surgery may be planned for a patient with cholecystitis who has been vomiting for several days. Also identify drugs that alter fluid and electrolyte status, such as diuretics. Serum electrolyte levels are often assessed before surgery. Many patients may have restricted fluids for some time before surgery. If the surgery is delayed, they could develop dehydration. A patient with or at risk for dehydration may require additional fluids and electrolytes before or during surgery.

Although a preoperative fluid balance history should be completed for all patients, it is especially critical for older adults. Their reduced adaptive capacity leaves a narrow margin of safety between overhydration and underhydration.

Nutritional Status. Nutritional deficits include overnutrition and undernutrition, both of which require considerable time to correct. However, knowing that a patient has a nutritional deficit can help the perioperative team provide more individualized care. For example, if the patient is thin, provide more padding than usual (pressure points on all patients are protected routinely) on the OR table. Notify the team if a patient is

morbidly obese (body mass index [BMI] greater than 40 kg/m^2) to allow time to obtain special equipment needed for the patient's care (e.g., longer instruments for abdominal surgery).

Obesity stresses both the cardiac and pulmonary systems and makes access to the surgical site and anesthesia administration more difficult.[13] It predisposes the patient to wound dehiscence, wound infection, and incisional herniation postoperatively. Adipose tissue is less vascular than other types of tissue. In addition, the patient may be slower to recover from anesthesia because inhalation agents are absorbed and stored by adipose tissue, thus leaving the body more slowly. (See Chapter 41 for special needs of obese patients undergoing surgery.)

Nutritional deficiencies impair the ability to recover from surgery. Remember that the obese patient and the very thin patient can also be protein and vitamin deficient. If the nutritional problem is severe, surgery may be postponed. Protein and vitamins A, C, and B complex deficiencies are particularly significant because these substances are essential for wound healing.[14] Supplemental nutrition may be administered during the perioperative period to patients who are malnourished. The older adult is often at risk for malnutrition and fluid volume deficits.[8]

Identify patients who consume large quantities of coffee or soft drinks containing caffeine. In many cases, withholding caffeinated beverages preoperatively or for some time postoperatively can lead to severe withdrawal headaches.[15] Caffeine withdrawal headaches can be confused with spinal headaches if the preoperative data are not documented. Giving caffeinated beverages postoperatively, when possible, may prevent these headaches.

Objective Data

Physical Examination. The Joint Commission requires that all patients admitted to the OR have a documented history and physical examination (H&P) in their chart.[16] This may be done in advance of surgery or on the day of surgery. It may be performed by any qualified person, including advanced practice nurses, physicians, physician assistants, or ACPs. Findings from the patient's H&P will enable the ACP to assign the patient a physical status rating for anesthesia administration (Table 18-3). This rating is an indicator of the patient's perioperative risk and may influence perioperative decisions.

TABLE 18-3 AMERICAN SOCIETY OF ANESTHESIOLOGISTS' PHYSICAL CLASSIFICATION SYSTEM

Rating	Definition
P1	Normal healthy person
P2	Patient with mild systemic disease
P3	Patient with severe systemic disease
P4	Patient with severe systemic disease that is a constant threat to life
P5	Moribund patient who is not expected to survive without surgery
P6	Declared brain-dead patient whose organs are being removed for donor purposes

Source: American Society of Anesthesiologists: ASA physical status classification system, 2012. Retrieved from *www.asahq.org/clinical/physicalstatus.htm*.
NOTE: Patients selected for surgery in ambulatory or outpatient settings generally have ratings of P1, P2, or P3.

In addition to the health assessment, also complete a physical examination of the patient before surgery (Table 18-4). Review the documentation already present in the patient's chart, including the H&P, to better proceed with your examination. Document all findings and communicate any relevant findings immediately to the surgeon or the ACP.

Laboratory and Diagnostic Testing. Obtain and assess the results of laboratory and diagnostic tests ordered preoperatively (Table 18-5). For example, if the patient is taking an antiplatelet medication (e.g., aspirin), a coagulation profile will be ordered; if the patient is on diuretic therapy, a potassium level is assessed; if the patient is of childbearing age, a pregnancy test should be ordered; or if the patient is taking medications for dysrhythmias, a preoperative ECG is obtained. Blood glucose monitoring is done for patients with diabetes. In some settings, tests for methicillin-resistant *Staphylococcus aureus* are done preoperatively. Patients with positive results are prescribed antibiotics for several days before surgery.[17]

Ideally, preoperative tests are ordered based on the patient's H&P. However, many facilities and insurers have a written protocol for preoperative tests, which may not include all the identified areas. In addition, the preoperative tests may be done days before surgery. Ensure that all laboratory and diagnostic reports are in the patient's chart. Missing reports may result in a delay or cancellation of the surgery.

NURSING MANAGEMENT PREOPERATIVE PATIENT

Preoperative nursing interventions are derived from the nursing assessment and must reflect each patient's specific needs. Physical preparations are determined by the pending surgery and the routines of the surgery setting. Preoperative teaching may be minimal or extensive. The Association of periOperative Registered Nurses (AORN) provides standards and recommended practices to guide nursing interventions in all perioperative settings.[7]

PREOPERATIVE TEACHING

The patient has a right to know what to expect and how to participate effectively during the surgical experience. Preoperative teaching increases patient satisfaction and may reduce postoperative fear, anxiety, and stress.[18] Teaching may also decrease the development of complications, the length of hospitalization, and the recovery time after discharge.

In most surgical settings, patients often arrive only a short time before surgery is scheduled. Preoperative teaching for these patients is generally done in the surgeon's office or a preadmission surgical clinic and reinforced on the day of surgery. After ambulatory surgery the patient usually goes home several hours after recovery, depending on the patient's progress and procedure-specific needs. Teaching must include information that focuses on the patient's safety. Provide written materials for patients and caregivers to use for review and reinforcement at home. Discharge teaching is required for all patients[19,20] and is discussed in Chapter 20.

When doing preoperative teaching for a patient, provide a balance between explaining so much that the patient is overwhelmed and telling so little that the patient is unprepared. If you observe carefully and listen sensitively to the patient, you can usually determine how much information is enough. Remember that anxiety and fear may decrease learning ability.

TABLE 18-4 HEALTH ASSESSMENT AND PHYSICAL EXAMINATION OF PREOPERATIVE PATIENT*

Cardiovascular System
- Identify acute or chronic problems. Note presence of angina, hypertension, heart failure, recent myocardial infarction, renal disease, diabetes.
- Identify any drugs (e.g., aspirin) or herbal supplements (e.g., ginkgo) that may affect coagulation.
- Identify patients with prosthetic heart valves, pacemakers, or implantable cardioverter-defibrillators.
- Assess for edema (including dependent areas), noting location and severity.
- Inspect neck veins for distention.
- Obtain bilateral baseline blood pressures.
- Assess pulses (bilaterally when appropriate) for rate, rhythm, and quality: apical, radial, and pedal.

Respiratory System
- Identify acute or chronic problems. Note the presence of infection, chronic obstructive pulmonary disease, or asthma. Note use of CPAP machine.
- Assess history of smoking, including the time since the last cigarette and the number of pack-years.
- Determine baseline respiratory rate and rhythm and regularity of pattern.
- Observe for cough, dyspnea, and use of accessory muscles of respiration.
- Auscultate lungs for normal and adventitious breath sounds.

Neurologic System
- Determine orientation to person, place, and time.
- Assess baseline mental status. Note presence of confusion, disorderly thinking, or inability to follow commands.
- Identify past history of strokes, transient ischemic attacks, or neurologic diseases (e.g., Parkinson's disease, multiple sclerosis).

Genitourinary System
- Identify any infection or preexisting disease.
- Determine ability to void.
- Note color, amount, and characteristics of urine (if appropriate).
- Determine pregnancy status (if appropriate).

Hepatic System
- Review past history of substance abuse, especially alcohol and IV drug use.
- Inspect skin color and sclera of eyes for any signs of jaundice.

Integumentary System
- Identify any current or previous skin disorders (e.g., pressure ulcers, eczema).
- Determine skin status. Note drying, bruising, or breaks in surface.
- Inspect skin for rashes, boils, or infection, especially around the planned surgical site.
- Inspect the mucous membranes and skin turgor for signs of dehydration.
- Assess skin moisture and temperature.

Musculoskeletal System
- Examine skin around bone pressure points.
- Assess for limitations in joint range of motion and muscle strength.
- Assess for joint or muscle pain.
- Assess mobility, gait, and balance.

Gastrointestinal System
- Determine patterns of food and fluid intake and any recent changes in weight.
- Determine usual pattern of bowel movements, including date of last bowel movement.
- Assess for the presence of dentures and bridges (loose dentures or teeth may be dislodged during intubation).
- Weigh patient.
- Auscultate abdomen for presence of bowel sounds.

Immune System
- Identify any immunodeficiency or autoimmune disorders.
- Assess for use of corticosteroids or other immunosuppressant drugs.

Laboratory and Diagnostic Tests
- Review results of all laboratory and diagnostic tests completed preoperatively (see Table 18-5).

*See specific body system chapters for more detailed assessments and related laboratory studies.
CPAP, Continuous positive airway pressure.

Also assess what the patient wants to know and give priority to those concerns.

Generally, preoperative teaching includes three types of information: sensory, process, and procedural. Different patients, with varying cultures, backgrounds, and experience, may want different types of information.

With *sensory information,* patients find out what they will see, hear, smell, and feel during the surgery. For example, you may tell them that the OR will be cold, but they can ask for a warm blanket; the lights in the OR are bright; or many unfamiliar sounds and specific smells will be present.

Patients wanting *process information* may not want specific details but just the general flow of what is going to happen. This information would include the patient's transfer to the holding area, visits by the nurse and the ACP before transfer to the OR, and waking up in the PACU.

With *procedural information,* patients desire details that are more specific. For example, this information would include that an IV line will be started while the patient is in the holding area and the surgeon will mark the operative area with an indelible marker to verify site and side.[7]

Share the preoperative teaching provided to the patient with the nurses providing postoperative care to evaluate learning and avoid duplication of teaching. Because the time for teaching is limited, the team approach is often used. For example, teaching may be started in the outpatient setting. Your responsibility is to assess the patient's understanding of this teaching and fill in the gaps. The discharge nurse provides written instructions and additional information for reinforcement. Home care nurses may be involved if patients have complex learning needs that must be addressed after discharge.

Document all teaching in the patient's chart. A Patient & Caregiver Teaching Guide for preoperative preparation is presented in Table 18-6. Additional information related to patient and caregiver teaching is found in Chapter 4.

GENERAL SURGERY INFORMATION. Unless contraindicated (e.g., after craniotomy, tonsillectomy), all patients should receive instruction about deep breathing, coughing, and early ambulation (moving) postoperatively. This is essential because patients may not want to do these activities postoperatively unless they are taught the reason for them and practice them preoperatively. Tell patients and caregivers if tubes, drains, monitoring devices, or special equipment will be used after surgery. Explain that these devices help you to safely care for the patient. Examples of individualized teaching may include how to use incentive spirometers or postoperative patient-controlled analgesia

TABLE 18-5 COMMON PREOPERATIVE LABORATORY AND DIAGNOSTIC TESTS

Test	Assessment
ABGs, pulse oximetry	Respiratory and metabolic function, oxygenation status
Blood glucose	Metabolic status, diabetes mellitus
Blood urea nitrogen, creatinine	Renal function
Chest x-ray	Pulmonary disorders, cardiac enlargement, heart failure
Complete blood count: RBCs, Hgb, Hct, WBCs, WBC differential	Anemia, immune status, infection
Electrocardiogram	Cardiac disease, dysrhythmias
Electrolytes	Metabolic status, renal function, diuretic side effects
hCG	Pregnancy status
Liver function tests	Liver status
PT, PTT, INR, platelet count	Coagulation status
Pulmonary function studies	Pulmonary status
Serum albumin	Nutritional status
Type and crossmatch	Blood available for replacement (elective surgery patients may have own blood available)
Urinalysis	Renal status, hydration, urinary tract infection

hCG, Human chorionic gonadotropin; *Hct,* hematocrit; *Hgb,* hemoglobin; *INR,* international normalized ratio; *PT,* prothrombin time; *PTT,* partial thromboplastin time.

pumps. Patients should have a clear understanding of how to rate their pain intensity and how their pain will be managed.[21] (See Chapter 9 for additional information on pain.)

The patient should also receive accurate surgery-specific information. For example, a patient having a total joint replacement may have an immobilizer after surgery, or a patient with extensive neurosurgery should be told about waking up in the intensive care unit.

AMBULATORY SURGERY INFORMATION. The ambulatory surgery patient or the patient admitted to the hospital the day of surgery needs to receive information before admission. Some ambulatory surgical centers telephone the patients the evening before surgery to answer last-minute questions and to reinforce teaching. Each center has policies and procedures that direct this communication in a timely manner.

In addition to specifics on the procedure, patients need information on day-of-surgery events such as arrival time, registration, parking, what to wear, what to bring, and the need to have a responsible adult present for transportation home after surgery.

Traditionally, patients having elective surgery are instructed to have nothing by mouth (NPO) starting at midnight on the night before surgery. Current guidelines published by the American Society of Anesthesiologists are less strict[22] (Table 18-7). Restriction of fluids and food is designed to reduce the risk of pulmonary aspiration and postoperative nausea and vomiting. Protocols may vary for patients having local anesthesia or surgery scheduled late in the day. Follow the NPO protocol of each surgical facility. The patient who has not followed the NPO instructions may have surgery delayed or canceled. It is critical that the patient understands the reason for and follows all restrictions.

TABLE 18-6 PATIENT & CAREGIVER TEACHING GUIDE

Preoperative Preparation

Include the following information in the preoperative teaching plan for patient and caregiver.

Sensory Information

- Preoperative holding area may be noisy.
- Drugs and cleaning solutions may be cold and odorous.
- Operating room (OR) can be cold. Warm blankets are available and can be requested.
- Talking may be heard in the OR but may be distorted because of masks. Ask questions if something is not understood.
- OR bed will be narrow. A safety strap will be applied over the thighs.
- Lights in the OR may be bright.
- Monitoring machines may be heard (e.g., ticking and beeping noises) when awake.

Procedural Information

- What to bring and what type of clothing to wear to the surgery center.
- Any changes in time of surgery.
- Fluid and food restrictions.
- Physical preparation required (e.g., bowel or skin preparation).
- Purpose of frequent vital signs assessment.
- Pain control and other comfort measures.
- Why turning, coughing, and deep breathing postoperatively are important. Practice sessions need to be done preoperatively.
- Insertion of IV lines.
- Procedure for anesthesia administration.
- Expect surgical site and/or side to be marked with indelible ink or marker.

Process Information

Information About General Flow of Surgery

- Admission area.
- Preoperative holding area, OR, and recovery area.
- Caregivers can usually stay in preoperative holding area until surgery.
- Caregivers will be able to see the patient after discharge from the recovery area or possibly in the recovery area once the patient is awake.
- Identification of any technology that may be present on awakening, such as monitors and central lines.

Where Caregivers Can Wait During Surgery

- Encourage caregivers to ask questions and express any concerns.
- OR staff will update caregivers during surgery and when surgery is completed.
- Surgeon will usually talk with caregivers after surgery.

LEGAL PREPARATION FOR SURGERY

Legal preparation for surgery consists of checking that all required forms have been correctly signed and are present in the patient's chart, and that the patient and the caregiver clearly understand what is going to happen. Standard consent forms include those for the surgical procedure and blood transfusions. Other forms may include advance directives and durable power of attorney for health care (see Chapter 10).

CONSENT FOR SURGERY. Before nonemergency surgery can be legally performed, the patient must voluntarily sign an informed consent form in the presence of a witness. **Informed consent** is an active, shared decision-making process between the health care provider and the recipient of care.[23] Three conditions must be met for consent to be valid. First, there must be *adequate*

TABLE 18-7 PREOPERATIVE FASTING RECOMMENDATIONS*

Liquid and Food Intake	Minimum Fasting Period (Hr)
Clear liquids (e.g., water, clear tea, black coffee, carbonated beverages, fruit juice without pulp)	2
Breast milk	4
Nonhuman milk, including infant formula	6
Light meal (e.g., toast and clear liquids)	6
Regular meal (may include fried or fatty food, meat)	8 or more

Retrieved from *http://journals.lww.com/anesthesiology/Fulltext/2011/03000/Practice_Guidelines_for_Preoperative_Fasting_and.13.aspx?WT.mc_id=HPxADx20100319xMP*.

*For healthy patients of all ages undergoing elective surgery (excluding women in labor).

EVIDENCE-BASED PRACTICE

Applying the Evidence

G.L. is a 57-year-old woman scheduled for a knee replacement. She has been NPO since midnight and was scheduled to be the third surgical case of the day. Unfortunately, several emergency surgeries have resulted in delays, and she is not expected to leave for surgery for another 4 hours. She tells you that she has a "headache" from missing her "morning coffee." She says she is hungry and thirsty and, since surgery has been delayed, she would like a cup of coffee.

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
For healthy adults, the minimum fasting period for clear liquids before surgery is 2 hr.	Nothing by mouth (NPO) restrictions are meant to prevent aspiration and vomiting during surgery. Patients who are NPO from midnight frequently complain of hunger and thirst while waiting for surgery. Patients who regularly drink caffeine in the morning often experience a "caffeine withdrawal" headache when fasting. You know that clear liquids consist of water, fruit juices without pulp, carbonated beverages, clear tea, and black coffee.	Patient is requesting something to drink given the extended period of fast due to the delay in surgery.

Your Decision and Action

You know that the current protocol of keeping all patients NPO after midnight for surgery does not reflect the best available evidence. You also know that there is a multidisciplinary task force working to review and revise the protocol. You decide to call the anesthesia care provider to discuss G.L.'s situation and request that clear liquids be ordered for her.

References for Evidence

American Society of Anesthesiologists Committee on Standards and Practice Parameters: Practice guidelines for preoperative fasting and the use of pharmacologic agents to reduce the risk of pulmonary aspiration: application to healthy patients undergoing elective procedures: an updated report by the ASA Committee on Standards and Practice Parameters, *Anesthesiology* 114(3):495, 2011.

Crenshaw JT: Preoperative fasting: will the evidence ever be put into practice? *Am J Nurs* 111:38, 2011.

disclosure of the diagnosis; the nature and purpose of the proposed treatment; the risks and consequences of the proposed treatment; the probability of a successful outcome; the availability, benefits, and risks of alternative treatments; and the prognosis if treatment is not instituted. Second, the patient must demonstrate clear *understanding* of the information being provided before receiving sedating preoperative medications. Third, the recipient of care must *give consent voluntarily.* The patient must not be persuaded or coerced in any way by anyone to undergo the procedure.[24]

The physician is ultimately responsible for obtaining the patient's consent for surgical treatment. You may be responsible for witnessing the patient's signature on the consent form. At this time, you can be a patient advocate, verifying that the patient (or caregiver) understands the information presented in the consent form and the implications of consent, and that consent for surgery is truly voluntary. If the patient is unclear about the surgical plans, contact the surgeon about the patient's need for additional information. The patient should also be aware that consent, even when signed, can be withdrawn at any time.

If the patient is a minor, unconscious, or mentally incompetent to sign the permit, a legally appointed representative or responsible family member may give written permission. An *emancipated minor* is one who is younger than the legal age of consent but is recognized as having the legal capacity to provide consent.[25] Procedures for obtaining consent vary among states and agencies. Follow specifics required by your state's nurse practice act and agency policies that apply to an individual situation.

ETHICAL/LEGAL DILEMMAS

Informed Consent

Situation

J.S., a 72-year-old woman, is waiting in the preoperative holding area. You are discussing her impending surgery when you realize that this competent adult does not fully understand her surgery and was not informed of the alternatives to this surgery. Although she has previously signed a consent form, your assessment is that she was not fully informed about her treatment options or does not recall them.

Ethical/Legal Points for Consideration

- Informed consent requires that patients have complete information about the proposed treatment, as well as alternative treatments, risks and benefits of each treatment option, and possible consequences of the surgical procedure. The person (usually the surgeon) performing the procedure usually has this responsibility.
- An opportunity to have questions answered about the various treatment options and their possible outcomes is also an important element of informed consent.
- A patient can revoke the consent at any time, even at the very last minute. It is essential that you report any circumstance that suggests that the patient does not understand the information or is revoking the informed consent to the person who obtained the consent.
- In most states, the registered nurse's legal role is to witness the signing of the document. This means that as a nurse, you attest to the fact that the patient's signature was valid.

Discussion Questions

1. What do you think you should do next?
2. What is your role as a patient advocate in the informed consent process?
3. What should you do if the patient states that she does not want to know about the surgical procedure or alternatives to surgery?

A true medical emergency may override the need to obtain consent. When immediate medical treatment is needed to preserve life or to prevent serious impairment to life or limb and the patient is incapable of giving consent, the next of kin may give consent. If reaching the next of kin is not possible, the physician may begin treatment without written consent. A note is written in the chart documenting the medical necessity of the procedure. In the case of an emergency where consent cannot be obtained, the perioperative nurse usually needs to complete an event report because it is an occurrence that is inconsistent with routine facility practices.[26]

DAY-OF-SURGERY PREPARATION

NURSING ROLE. Day-of-surgery preparation varies a great deal depending on whether the patient is an inpatient or an ambulatory surgical patient. Your responsibilities immediately before surgery include final preoperative teaching, assessment, and communication of pertinent findings. In addition, ensure that all preoperative orders are done and that the chart is complete and accompanies the patient to the OR. It is especially important to verify the presence of a signed informed consent, laboratory and diagnostic data, an H&P, a record of any consultations, baseline vital signs, and completed nursing notes. In addition, the site and side of the anticipated surgery are identified and marked with an indelible marker by the surgeon and documented to indicate the patient agrees.[9]

Hospitals often require that a patient wear a hospital gown with no underclothes. Surgical centers may allow the patient to wear underwear, depending on the procedure to be performed. The patient should remove any cosmetics, since observation of skin color is important. Nail polish and artificial nails should be removed so that capillary refill and pulse oximetry can be assessed. Place an identification band on the patient and, if applicable, an allergy band (Fig. 18-1). Return all patient valuables to a caregiver or secure according to institutional protocol. All prostheses, including dentures, contact lenses, and glasses, are generally removed to prevent loss or damage. If electrocautery devices will be used during surgery, jewelry in piercings needs to be removed as a safety measure. Hearing aids should be left in place to allow the patient to better follow instructions. Return glasses to the patient as soon as possible after surgery. Encourage the patient to void before preoperative medications are given and before transfer to the OR. Many preoperative medications interfere with balance and increase the risk for a fall during ambulation. An empty bladder prevents involuntary elimination under anesthesia and reduces the possibility of urinary retention during the early postoperative recovery.

FIG. 18-1 The nurse performs a safety check by verifying that the patient has an identification band (wristband) as part of the preoperative preparations before she goes to surgery.

SAFETY ALERT

Use a preoperative checklist (Table 18-8) to ensure that all preoperative preparations have been completed before the patient is given any sedating medications.

PREOPERATIVE MEDICATIONS. Preoperative medications are used for a variety of reasons (Table 18-9). A patient may receive a single drug or a combination of drugs. Benzodiazepines are used for their sedative and amnesic properties. Anticholinergics are sometimes given to reduce secretions. Opioids may be given to decrease pain and intraoperative anesthetic requirements. Antiemetics may be given to decrease nausea and vomiting.

Other medications that may be administered preoperatively include antibiotics, eyedrops, and routine prescription drugs. Antibiotics may be administered throughout the perioperative period for patients with a history of congenital or valvular heart disease to prevent infective endocarditis and for patients with previous joint replacement. Antibiotics may also be ordered for the patient undergoing surgery where wound contamination is a potential risk (e.g., gastrointestinal surgery) or where wound infection could have serious postoperative consequences (e.g., cardiac and joint replacement surgery). Antibiotics are most commonly administered IV and are usually started preoperatively (e.g., 30 to 60 minutes before the surgical incision).

β-Adrenergic blockers (β-blockers) are sometimes used in people with known hypertension or coronary artery disease to control BP or reduce the chances of myocardial infarction and cardiac arrest.[27] People with diabetes are also carefully monitored and may receive insulin in the preoperative period.[28] Eyedrops are often ordered and given preoperatively for the patient undergoing cataract and other eye surgery. Many times the patient will require multiple sets of eyedrops given at 5-minute intervals. It is important to give these drugs as ordered and on time to adequately prepare the eye for surgery.

Medications that patients routinely take may or may not be used on the day of surgery. To facilitate patient teaching and eliminate confusion about which medications should be taken, carefully check written preoperative orders and clarify the orders with the surgeon and/or ACP if there is any question.

Preoperative medications may be ordered by mouth (PO), IV, or subcutaneously. Provide PO medications with a small sip

INFORMATICS IN PRACTICE

Computer-Based Timing for Antibiotic Administration

- A patient who receives the appropriate preoperative antibiotic has a decreased risk of a health care–associated infection.
- Using a computer to time the administration of preoperative antibiotics can decrease the incidence of wound infections.
- Computer-based timing systems assist with quality of care by tracking patient outcomes.
- You can look at the time patients received antibiotics and compare the rate of wound infections for those who did and did not receive timely treatment.

Time to OR _____ Date _____
Transported to OR by _____
Final check by _____ RN _____

of water 60 to 90 minutes before the patient goes to the OR unless otherwise ordered. Subcutaneous injections (e.g., insulin) and IV medications are usually given to the patient after arrival in the preoperative holding area or OR. Inform the patient about the expected effects of the medications (e.g., drowsiness).

TRANSPORTATION TO THE OPERATING ROOM

For inpatients, transport staff move the patient by stretcher to the OR. Assist the patient in moving from the hospital bed to the stretcher, raise the side rails, and ensure that the completed chart and any ordered preoperative equipment (e.g., sequential compression devices) goes with the patient. In many institutions the caregiver may accompany the patient to the holding area.

In an ambulatory surgical center the patient may be transported to the OR by stretcher or wheelchair. If no sedatives have been given, the patient may even walk accompanied to the OR. In all cases it is important to ensure patient safety during transport. Document the method of transportation and the person who transports the patient to the OR. You are also responsible for the hand-off communication to the nurse receiving the patient. This provides an opportunity for each of you to ensure that all pertinent information regarding the patient has been shared.[29] To avoid adverse events related to miscommunication, AORN recommends the use of the Situation-Background-Assessment-Recommendation (SBAR) model for the hand-off process in this setting[30,31] (see Table 1-7).

Show the caregiver where to wait for the patient during surgery. Many hospitals have a surgical waiting room where OR personnel communicate the patient's status to the caregiver(s) and notify them when the surgery is complete. The surgeon also can locate the caregiver in this room after surgery to discuss the outcome. Some hospitals provide pagers to caregivers so that they may eat or do errands during the surgery.

CULTURALLY COMPETENT CARE

PREOPERATIVE PATIENT

Include cultural considerations when assessing and implementing care for the patient's preoperative needs. For example,

TABLE 18-9 DRUG THERAPY

Commonly Used Preoperative Medications

Class	Drug	Purpose
Antibiotics	cefazolin (Ancef)	Prevent postoperative infection
Anticholinergics	atropine (Isopto Atropine) glycopyrrolate (Robinul)	↓ Oral and respiratory secretions
	scopolamine (Transderm-Scōp)	Prevent nausea and vomiting Provide sedation
Antidiabetics	insulin (Humulin R)	Stabilize blood glucose
Antiemetics	metoclopramide (Reglan)	↑ Gastric emptying
	ondansetron (Zofran)	Prevent nausea and vomiting
Benzodiazepines	midazolam (Versed) diazepam (Valium) lorazepam (Ativan)	↓ Anxiety, induce sedation, amnesic effects
β-Blockers	labetalol (Normodyne)	Manage hypertension
Histamine (H_2)-receptor antagonists	famotidine (Pepcid) ranitidine (Zantac)	↓ HCl acid secretion, ↑ pH, ↓ gastric volume
Opioids	morphine (Duramorph) fentanyl (Sublimaze)	Relieve pain during preoperative procedures

culture often determines one's expression of pain, family expectations, and ability to verbally express needs. One's culture may require that the family be included in any decision making. For example, many older Hispanic women may defer to their family for the decision to have or not to have surgery. Respect these decisions. If the patient or caregiver does not speak English, it is mandated that a qualified translator or translator communication system be used.[32] (Culturally competent care is discussed in Chapter 2.)

GERONTOLOGIC CONSIDERATIONS

PREOPERATIVE PATIENT

Many surgical procedures are performed on patients older than 65 years of age. Surgery on older adults requires careful evaluation.[33] Frequently performed procedures in older adults include cataract extraction, coronary and vascular procedures, prostate surgery, herniorrhaphy, cholecystectomy, and joint repair or replacement.

Be particularly alert when assessing and caring for the older adult surgical patient. An event that has little effect on a younger adult may be overwhelming to the older patient. Emotional reactions to impending surgery and hospitalization often intensify in the older adult. Hospitalization may represent a physical decline and loss of health, mobility, and independence. The older adult may view the hospital as a place to die or as a stepping-stone to nursing home placement. Help to decrease anxieties and fears, as well as maintaining and restoring the self-esteem of the older adult during the surgical experience.

The risks associated with anesthesia and surgery increase in the older patient.[33] In general, the older the patient, the greater the risk of complications after surgery. In planning care, consider the patient's physiologic status, not simply the chronologic age. The surgical risk in the older adult relates to normal physiologic aging and changes that compromise organ function, reduce reserve capacity, and limit the body's ability to adapt to stress. This decreased ability to cope with stress, often compounded by the burden of one or more chronic illnesses, and the surgery itself increase the risk of complications.

When preparing the older adult for surgery, obtain a detailed H&P. Preoperative laboratory tests, an ECG, and a chest x-ray are important in planning the choice and type of anesthesia. The patient's primary physician is usually not the surgeon, and frequently several physicians are involved in the patient's care. Help to coordinate the care for the older adult patient.

Many older adults have sensory deficits. Vision and hearing may be reduced, and bright lights may bother those with eye problems. Thought processes and cognitive abilities may be slowed or impaired. Assess and document baseline sensory and cognitive function. Physical reactions are often slowed as a result of mobility and balance problems. All these changes may require more time for the older adult to complete preoperative testing and understand preoperative instructions. These changes also require attention to promote patient safety and prevent injury. (See Chapter 5 for more discussion about older adults.)

When older adults live in some type of long-term care facility, you may need to coordinate transportation from these agencies so that timely arrival allows for surgery preparation. A legal representative of the patient must be present to provide consent for surgery if the patient cannot sign for himself or herself.

Finally, determine the presence of or need for caregiver support for the older adult undergoing surgery. With the increase in outpatient surgical procedures and shorter postoperative length of stays, caregiver support is often critical in the continuity of care for this population.

CASE STUDY

Preoperative Patient

Ryan McVay/Photodisc/Thinkstock

Patient Profile

F.D., a 72-year-old Hispanic retired librarian, is admitted to the hospital with compromised circulation of the right lower leg and a necrotic right foot. She has diabetes and takes insulin to maintain appropriate blood glucose levels. In addition, she has hypertension and kidney and peripheral vascular disease. She has been NPO since midnight. It is now 10 AM on the morning of the surgery.

Subjective Data

- History of type 2 diabetes mellitus for 30 years; states "my blood sugar is hard to control" and "I just started taking insulin"
- History of hypertension
- History of stage 2 chronic kidney disease
- History of peripheral vascular disease
- History of macular degeneration in right eye; reports poor vision
- Surgical history: cesarean section at age 30, cholecystectomy at age 65; reports poor wound healing after last surgery
- Social Security checks barely cover the cost of living
- States she often runs out of medications and cannot always afford to refill them right away
- Reports chronic burning pain in both legs and has trouble sleeping at night
- Lives alone but has family who want her to move in with them after surgery
- Uses herbs to control blood glucose levels and frequently skips her insulin

Objective Data

Physical Examination

- Alert, cognitively intact, anxious, older woman with complaints of numbness and lack of feeling in right leg
- Weight 190 lb, height 5 ft 3 in
- BP 180/94, pulse 84 and slightly irregular
- Wears glasses for close work and reading
- Has macular degeneration in right eye

Diagnostic Studies

- Admission serum blood glucose level 272 mg/dL (15.2 mmol/L); glycosylated hemoglobin (Hb A1C) 14%
- Morning capillary blood glucose level 198 mg/dL (11 mmol/L)
- Doppler pulses for right lower leg weak, absent in right foot
- Doppler pulses in left lower leg present, weak in left foot
- Serum creatinine 2.0 mg/dL (176 mmol/L)

Collaborative Care

- Scheduled for a below-the-knee amputation of the right leg at 1 PM today

Discussion Questions

1. What factors may influence F.D.'s response to hospitalization and surgery?
2. ***Priority Decision:*** Given F.D.'s history, what priority preoperative nursing assessments would you want to complete and why?
3. What potential perioperative complications might you expect for F.D.?
4. ***Priority Decision:*** What priority topics would you include in F.D.'s preoperative teaching plan?
5. ***Priority Decision:*** Based on the assessment data presented, identify the priority nursing diagnoses and related interventions. Are there any collaborative problems?
6. ***Delegation Decision:*** Identify appropriate preoperative interventions that need to be completed and could be delegated to unlicensed assistive personnel (UAP).
7. ***Evidence-Based Practice:*** F.D. asks you why she received insulin this morning when she has not eaten anything since midnight. How would you respond to her?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. An overweight patient (BMI 28.1 kg/m^2) is scheduled for a laparoscopic cholecystectomy at an outpatient surgery setting. The nurse knows that
   - **a.** surgery will involve multiple small incisions.
   - **b.** this setting is not appropriate for this procedure.
   - **c.** surgery will involve removing a portion of the liver.
   - **d.** the patient will need special preparation because of obesity.
2. The patient tells the nurse in the preoperative setting that she has noticed she has a reaction when wearing rubber gloves. What is the most appropriate intervention?
   - **a.** Notify the surgeon so the case can be cancelled.
   - **b.** Ask additional questions to assess for a possible latex allergy.
   - **c.** Notify the OR staff immediately so that latex-free supplies can be used.
   - **d.** No intervention is needed because the patient's rubber sensitivity has no bearing on surgery.
3. A 59-year-old man is scheduled for a herniorrhaphy in 2 days. During the preoperative evaluation he reports that he takes ginkgo daily. What is the priority intervention?
   - **a.** Inform the surgeon, since the procedure may need to be rescheduled.
   - **b.** Notify the anesthesia care provider, since this herb interferes with anesthetics.
   - **c.** Ask the patient if he has noticed any side effects from taking this herbal supplement.
   - **d.** Tell the patient to continue to take the herbal supplement up to the day before surgery.

4. A 17-year-old patient with a leg fracture is scheduled for surgery. She reports that she is living with a friend and is an emancipated minor. She has a statement from the court for verification. Which intervention is most appropriate?
   a. Witness the permit after consent is obtained by the surgeon.
   b. Call a parent or legal guardian to sign the permit, since the patient is under 18.
   c. Obtain verbal consent, since written consent is not necessary for emancipated minors.
   d. Investigate your state's nurse practice act related to emancipated minors and informed consent.
5. A priority nursing intervention to assist a preoperative patient in coping with fear of postoperative pain would be to
   a. inform the patient that pain medication will be available.
   b. teach the patient to use guided imagery to help manage pain.
   c. describe the type of pain expected with the patient's particular surgery.
   d. explain the pain management plan, including the use of a pain rating scale.
6. A patient is scheduled for surgery requiring general anesthesia at an ambulatory surgical center. The nurse asks him when he ate last. He replies that he had a light breakfast a couple of hours before coming to the surgery center. What should the nurse do first?
   a. Tell the patient to come back tomorrow, since he ate a meal.
   b. Proceed with the preoperative checklist, including site identification.
   c. Notify the anesthesia care provider of when and what the patient last ate.
   d. Have the patient void before administering any preoperative medications.
7. A patient who normally takes 40 units of glargine insulin (long acting) at bedtime asks the nurse what to do about her dose the night before surgery. The best response would be to have her
   a. skip her insulin altogether the night before surgery.
   b. take her usual dose at bedtime and eat a light breakfast in the morning.
   c. eat a moderate meal before bedtime and then take half her usual insulin dose.
   d. get instructions from her surgeon or health care provider on any insulin adjustments.
8. Preoperative considerations for older adults include *(select all that apply)*
   a. only using large-print educational materials.
   b. speaking louder for patients with hearing aids.
   c. recognizing that sensory deficits may be present.
   d. providing warm blankets to prevent hypothermia.
   e. teaching important information early in the morning.

1. a, 2. b, 3. a, 4. a, 5. d, 6. c, 7. d, 8. c, d

LEARNING OUTCOMES

1. Differentiate the purposes of the various areas of the perioperative/surgery department and the proper attire for each area.
2. Differentiate the roles and responsibilities of the interdisciplinary surgical team members.
3. Prioritize needs of patients undergoing surgery.
4. Analyze the role of the perioperative nurse in the management of the patient undergoing surgery.
5. Apply basic principles of aseptic technique used in the operating room.
6. Evaluate the importance of safety in the operating room relative to patients, equipment, and anesthesia.
7. Differentiate the common types of and delivery systems for anesthesia.

spinal anesthesia, p. 345

Historically, surgery took place in the traditional environment of the hospital operating room (OR). However, now the majority of surgical procedures are performed as ambulatory surgery (outpatient surgery). This chapter includes a discussion of the intraoperative care that is applicable to all surgical patients regardless of where the surgery if performed.

PHYSICAL ENVIRONMENT OF OPERATING ROOM

Department Layout

The *surgical suite* is a controlled environment designed to minimize the spread of pathogens and allow a smooth flow of patients, staff, and equipment needed to provide safe patient care. The suite is divided into three distinct areas: unrestricted, semirestricted, and restricted areas. The *unrestricted area* is where people in street clothes can interact with those in surgical attire. These areas typically include the points of entry for patients (e.g., holding area), staff (e.g., locker rooms), and information (e.g., nursing station or control desk). The *semirestricted area* includes the surrounding support areas and corridors. Only authorized staff are allowed access to the semirestricted areas. All staff in the semirestricted area must wear surgical attire and cover all head and facial hair. In the *restricted area* masks are required to supplement surgical attire.[1] The restricted area can include the OR, scrub sink area, and clean core.

In addition, the physical layout is designed to reduce cross-contamination. The flow of clean and sterile supplies and equipment should be separated from contaminated supplies,

*Contributed section on anesthesia content.

Reviewed by Ronald R. Castaldo, CRNA, MBA, MS, CCRN, Staff Nurse Anesthetist, Anesthesia Services, New Castle, Delaware; Lisa Kiper, RN, MSN, Assistant Professor of Nursing, Morehead State University, Morehead, Kentucky; Angela M. Martinelli, RN, PhD, CNOR, Science Officer, Congressionally Directed Medical Research Programs, Fort Detrick, Maryland; and Cynthia Schoonover, RN, MS, CCRN, Associate Nursing Professor, Sinclair Community College, Dayton, Ohio and PACU Staff Nurse, Kettering Medical Center, Kettering, Ohio.

equipment, and waste by space, time, and traffic patterns. Staff move supplies from clean areas, such as the clean core, through the OR for surgery, and on to the surrounding areas, such as the instrument decontamination area.[2]

Holding Area

The *holding area,* frequently called the *preoperative holding area,* is a special waiting area inside of or adjacent to the surgical suite. The size can range from a centralized area to accommodate numerous patients to a small designated area immediately outside the actual room scheduled for the surgical procedure. The holding area is where you identify and assess the patient before transferring him or her to the OR.

The *Surgical Care Improvement Project* (SCIP) is a national quality partnership of organizations focused on improving surgical care by significantly reducing the number of complications from surgery[3] (refer to *www.jointcommission.org/assets/1/6/Surgical%20Care%20Improvement%20Project.pdf*). Several SCIP measures may be implemented in the holding area, such as drug administration, patient warming, and application of sequential compression devices (SCDs). Many minor procedures (e.g., inserting IV catheters and arterial lines) can also be performed here.

The National Patient Safety Goals (NPSGs) require a preprocedure process, including the verification of relevant documentation (e.g., history and physical examination, signed consent form, nursing and preanesthesia assessment). In addition, any required blood products, implants, devices, and special equipment need to be available. Further, any diagnostic and radiology test results (e.g., x-rays, biopsy reports) need to be properly labeled and displayed.[4]

In addition, the NPSGs require that the surgeon mark the procedure site. If possible, the marking should be done with the patient's involvement.[4]

In some settings, another area for holding is identified as the *admission, observation, and discharge* (AOD) area. This area is designed to allow early-morning admission for outpatient surgery, same-day admission, and inpatient holding before surgery. In this area you can assess preoperative information, observe the patient both before and after surgery, and allow sufficient recovery time before the patient is discharged to either the home or an inpatient room. The AOD area is important in the patient's stay throughout outpatient surgery and prevents unnecessary overnight stays in the inpatient setting.

Separation from caregivers just before surgery can produce anxiety for the patient. This anxiety can be reduced when the caregiver is permitted to wait with the patient in the holding area until the patient is transferred to the OR.

Operating Room

The traditional surgical environment, or OR, is a unique setting removed from other hospital clinical units. It is controlled geographically, environmentally, and bacteriologically, and it is restricted in terms of the inflow and outflow of staff (Fig. 19-1). It is preferable to have the OR located next to the postanesthesia care unit (PACU) and the surgical intensive care unit. This allows for quick transport of the postoperative patient and close proximity to anesthesia staff if complications arise.

Several methods are used to prevent the transmission of infection. Filters and controlled airflow in the ventilating systems provide dust control. Positive air pressure in the rooms prevents air from entering the OR from the halls and corridors.

FIG. 19-1 Typical operating room.

Ultraviolet (UV) lighting may be used because UV radiation reduces the number of microorganisms in the air. Dust-collecting surfaces such as open shelves and tables are omitted. Materials that are resistant to the corroding effects of strong disinfectants are used.

Overall safety and comfort are aided by the use of OR furniture that is adjustable, easy to clean, and easy to move. All equipment is checked frequently to ensure proper functioning and electrical safety. The lighting is designed to provide a low- to high-intensity range for a precise view of the surgical site (see Fig. 19-2). A communication system provides a means for the delivery of routine and emergency messages.[5,6]

SURGICAL TEAM

Registered Nurse

The *perioperative nurse* is a registered nurse (RN) who implements patient care during the perioperative period. Through close collaboration with the other members of the surgical team, you prepare the OR for patients before they arrive. You are usually the first member of the surgical team who meets the patient. You are the patient's advocate throughout the intraoperative experience. This includes maintaining the patient's safety, privacy, dignity, and confidentiality; communicating with the patient; and providing physical care. Assess the patient to determine any additional needs or tasks to complete before surgery. Provide physical and emotional comfort and patient and caregiver teaching regarding the upcoming surgery. In addition, work with the patient's caregivers, keeping them informed and answering questions. This is particularly important in day-surgery areas where caregivers must assume greater responsibility for preoperative and postoperative care.

In the perioperative role, you assume functions that involve either sterile or unsterile activities (Table 19-1). When you serve in the role of *scrub nurse,* you follow the designated scrub procedure, are gowned and gloved in sterile attire, and remain in the sterile field (Fig. 19-2). When you serve in the role of *circu-*

TABLE 19-1 INTRAOPERATIVE ACTIVITIES OF PERIOPERATIVE NURSE

Circulating, Nonsterile Activities

- Reviews anatomy, physiology, and surgical procedure
- Assists in preparing room, ensuring that supplies and equipment are available, in working order, and sterile (if required)
- Maintains aseptic technique in all required activities
- Monitors practices of aseptic technique in self and others
- Checks mechanical and electrical equipment and environmental factors
- Conducts a preprocedure verification process
- Assesses patient's physical and emotional status
- Verifies and implements ordered SCIP measures
- Plans and coordinates intraoperative nursing care
- Checks chart and relates pertinent data to team members
- Participates in the application of monitoring devices and insertion of invasive lines and other devices
- Assists with and ensures patient safety in transferring and positioning patient
- Assists with induction of anesthesia
- Monitors draping procedure
- Participates in surgical time-out
- Documents intraoperative care
- Prepares, records, labels, and sends blood, pathology, and any anatomic specimens to proper locations
- Measures blood, urine output, and other fluid loss
- Verifies, dispenses, and records medications used, including local anesthetics
- Coordinates all intraoperative activities with team members and other health-related staff and departments
- Maintains accurate count of sponges, needles, instruments, and medical devices that could be retained in the patient
- Accompanies patient to PACU
- Provides hand-off report to PACU nurse with information relevant to care of patient

Scrubbed, Sterile Activities

- Reviews anatomy, physiology, and surgical procedure
- Assists in preparing the operating room
- Completes surgical hand and arm scrub, and gowns and gloves self and other members of surgical team
- Prepares instrument table and organizes sterile equipment for functional use
- Assists with draping procedure
- Participates in surgical time-out procedure
- Passes instruments to surgeon and assistants by anticipating their needs
- Maintains accurate count of sponges, needles, instruments, and medical devices that could be retained in the patient
- Monitors practices of aseptic technique in self and others
- Keeps track of irrigation solutions used for calculation of blood loss
- Accepts, verifies, and reports medications used by surgeon and/or ACP, including local anesthetics

ACP, Anesthesia care provider; *PACU,* postanesthesia care unit; *SCIP,* Surgical Care Improvement Project.

FIG. 19-2 The complexity of surgery requires maintaining asepsis.

lating nurse, you remain in the unsterile field and so you are not gowned and gloved in sterile attire.

Ongoing assessment of the patient is essential because the patient's condition may change quickly. You respond to these changes and revise the plan of care as needed. Examples of nursing activities that characterize each phase surrounding the surgical experience are presented in Table 19-2.

As patients move through the surgical experience, they are cared for by many team members. Opportunities for error are created whenever clinical information is shared among these members.[7] The Joint Commission requires that all health care providers implement a standardized approach to hand-off communication. The perioperative RN ensures that a complete and accurate hand-off using a consistent format, such as SBAR (see Table 1-7), occurs every time the responsibility for patient care is transferred to another professional. Examples of such transfers include change of shift, surgeon to nurse, and OR nurse to postanesthesia nurse.

You also have the opportunity to become a certified operating room nurse (CNOR). Certification reflects expertise in surgical nursing. The credential is a personal commitment to higher standards that inspires credibility and confidence with patients and peers in the workplace.[8]

Licensed Practical/Vocational Nurse and Surgical Technologist

Depending on your state nurse practice act, the role of the circulating or scrub nurse may be filled by a licensed practical/vocational nurse or a surgical technologist. Surgical technologists may attend an associate degree program, a vocational training program, or a hospital or military training program. The Association of Surgical Technologists is an organization that sets standards for education, provides continuing education opportunities, and offers certification for surgical technologists.[9]

If the circulating nurse is not an RN, the licensed practical/vocational nurse or surgical technologist must have access to an RN at all times. You are responsible for supervising the licensed practical/vocational nurse or surgical technologist in the performance of all delegated nursing tasks.[10]

Surgeon and Assistant

The *surgeon* is the physician who performs the surgical procedure. The surgeon is primarily responsible for the following:

- Preoperative medical history and physical assessment, including need for surgical intervention, choice of surgical procedure, management of preoperative testing, and discussion of the risks of and alternatives to surgical intervention

TABLE 19-2 NURSING ACTIVITIES DURING SURGICAL EXPERIENCE*

Before	During	After
Assessment and Planning	**Implementation**	**Evaluation**
Home, Clinic, Holding Area	**Safety Maintenance**	**Postanesthesia, Discharge Area**
Initiates preoperative assessment	Ensures integrity of sterile field	Determines patient's response to surgical intervention
Plans teaching appropriate to patient's needs	Ensures that sponge, needle, instrument, and medical device counts are correct	Monitors ABCs, vital signs, level of consciousness
Involves caregiver	Positions patient to ensure correct alignment, exposure of surgical site, and prevention of injury	Safely administers medications
Surgical Unit	Prevents chemical injury from prepping solutions, pharmaceuticals, etc.	**Clinical Unit**
Completes preoperative assessment	Ensures safe use of electrical equipment	Evaluates effectiveness of nursing care in OR using patient outcome criteria
Coordinates patient teaching with staff	Safely administers medications	Determines patient's level of satisfaction with care given during perioperative period
Develops a plan of care that reflects patient's level of function and ability	**Monitoring Physical Status**	Determines patient's psychologic status
Surgical Suite	Monitors and reports changes in patient's vital signs	Assists with discharge planning
Conducts preprocedure verification	Monitors blood loss and urine output	**Home, Clinic**
Assesses patient's level of consciousness, skin integrity, mobility, emotional status, and functional limitations	**Monitoring Psychologic Status**	Seeks patient's perception of surgery in terms of effects of anesthetic agents, impact on body image, immobilization
Reviews chart	Provides emotional support to patient	Determines caregiver's perceptions of surgery
Ensures all supplies and equipment needed are available, functioning, and sterile, if appropriate	Stands near or touches patient during procedures	
	Ensures patient's right to privacy is maintained	
	Communicates patient's emotional status to health care team	

*List of activities is not all-inclusive.
ABCs, Airway, breathing, circulation.

- Patient safety and management in the OR
- Postoperative management of the patient

The surgeon's assistant can be a physician who functions in an assisting role during the surgical procedure. The assistant usually holds retractors to expose surgical areas and assists with hemostasis and suturing. In some instances, especially in educational settings, the assistant may perform some portions of the surgery under the surgeon's direct supervision. In many institutions the surgeon's assistant is a registered nurse first assistant or a physician's assistant (PA) who functions under the physician's direct supervision.

Registered Nurse First Assistant

The *registered nurse first assistant* (RNFA) works in collaboration with the surgeon to produce an optimal surgical outcome for the patient. The Association of periOperative Registered Nurses (AORN) position statement on RNFAs states that the perioperative nurse must have formal education for this role and works collaboratively with the surgeon, patient, and surgical team by handling tissue, using instruments, providing exposure to the surgical site, assisting with hemostasis, and suturing.[6,11] RNFA education programs are designed to provide RNs with the education necessary to assume this expanded role.[12] The RNFA can also obtain certification.

Anesthesia Care Provider

The **anesthesia care provider (ACP)** is a person who administers anesthesia and can be an anesthesiologist, nurse anesthetist, or anesthesiologist assistant (AA). **Anesthesiology** is a discipline within the practice of medicine that specializes in the following.

- Medically managing patients who are unconscious or insensible to pain and emotional stress during surgical and other medical procedures
- Protecting functions and vital organs under the stress of anesthetic, surgical, or other medical procedures
- Managing pain
- Managing cardiopulmonary resuscitation
- Managing problems in pulmonary care
- Managing critically ill patients in special care units

ACPs who are anesthesiologists are responsible for administering anesthetic agents to relieve pain and manage vital life functions (e.g., breathing, blood pressure [BP]) during surgery. After surgery they provide care during recovery.[13]

A **nurse anesthetist** is an RN who has graduated from an accredited nurse anesthesia program (minimally a master's degree program) and successfully completed a national certification examination to become a certified registered nurse anesthetist (CRNA). The CRNA scope of practice includes the following:[14]

- Performing and documenting a preanesthetic assessment and evaluation
- Developing and implementing a plan for delivering anesthesia
- Selecting and initiating the planned anesthetic technique
- Selecting, obtaining, and administering the anesthesia, adjuvant drugs, and fluids
- Selecting, applying, and inserting appropriate noninvasive and invasive monitoring devices
- Managing a patient's airway and pulmonary status
- Managing emergence and recovery from anesthesia
- Releasing or discharging patients from a PACU
- Ordering, initiating, or modifying pain relief therapy
- Responding to emergency situations by providing airway management, and administering emergency fluids and drugs
- Assuming additional responsibilities within the expertise of the individual

An *anesthesiologist assistant* (AA) is a specialty PA who functions under the direction of an anesthesiologist in many states. The AA has graduated from an accredited program (minimally

a master's degree program) and successfully completed a national certification examination. AAs participate in the provision of all types of anesthesia, including administering drugs, obtaining vascular access, applying and interpreting monitors, establishing and maintaining airways, and assisting with preoperative assessments.

NURSING MANAGEMENT PATIENT BEFORE SURGERY

The preoperative assessment of the surgical patient establishes baseline data for intraoperative and postoperative care. Preoperative care of the patient is discussed in Chapter 18. Some additional information is discussed in this chapter.

PSYCHOSOCIAL ASSESSMENT

Knowing about the activities that occur when a patient is moved into the surgical suite allows you to provide explanations and reassurances, especially to the anxious patient. You can usually answer general questions regarding surgery or anesthesia, such as "When will I go to sleep?" "Who will be in the room?" "When will my surgeon arrive?" "How much of my body will be exposed?" "Will I be cold?" "When will I wake up?" Specific questions relating to details of the surgical procedure and anesthesia may be referred to the surgeon or the ACP.

Performing a cultural and spiritual assessment can help you understand the patient's response to the surgical experience (see Tables 2-7 and Table 10-5 for additional information). For example, members of the Jehovah's Witness community may refuse blood transfusions.[15] For Muslims, the left hand is considered unclean, so you should use the right hand to give forms, drugs, and treatments.[16] Some Native American patients may request that surgically removed body tissue be preserved so that it may be buried. Some tattoos and body piercings may also have cultural meaning.[17] Some patients may have a prayer cloth or other traditional or sacred item with them. Consider spiritual needs and beliefs in the individualized plan of care. For patients who do not speak English, a qualified interpreter must be used (see Table 2-10).

PHYSICAL ASSESSMENT

Perform a thorough physical assessment during the preoperative preparation of the patient (see Chapter 18).

CHART REVIEW

Required chart data vary with agency policy, patient condition, and specific surgical procedures. Because ambulatory surgery facilities tend to have a healthier population, fewer tests may be required. Examples of data that are obtained during the preoperative assessment can be found in Tables 18-2 and 18-4. This information contributes to an understanding of past and present history, cardiopulmonary status, and potential for infection and other complications.

ADMITTING THE PATIENT

Hospital policy designates the protocol to be followed when admitting the patient to the holding area and OR. A general routine includes initial greeting, extension of human contact and warmth, and proper identification. A preprocedure verification process is conducted before the start of surgery. In some institutions this takes place in the holding area; in others it takes place in the OR itself.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Music Therapy

Music is an ancient healing tool recognized in the writings of Plato.

Scientific Evidence

Strong scientific evidence for use in reducing stress and anxiety and enhancing mood.*

Nursing Implications

- To be effective, the music selected needs to be appropriate for the situation. Music can have many different physiologic effects.
  - Listening to calming music can result in slower, deeper breathing and a decrease in heart rate and blood pressure. Both of these indicate relaxation.
  - Music with a faster pace can energize a person and promote mental alertness.
- Music therapy is safe in combination with other treatment approaches.

*Based on a systematic review of scientific literature. Retrieved from *www.naturalstandard.com*.

Complementary and alternative therapies such as therapeutic touch, aromatherapy, music therapy, guided imagery, and even movies may be used for surgical patients. (See the Complementary & Alternative Therapies box above on music and Chapter 6.) These therapies may decrease anxiety, promote relaxation, reduce pain, and accelerate the healing process.[6,18] In some facilities these therapies are initiated before the patient's admission to the OR. In others, such as ambulatory settings, they may be started after the patient's arrival in the holding area.

The admitting procedure is continued with reassessment of the patient and with time allowed for last-minute questions. Complete the chart review for the previously mentioned data and note any abnormalities or changes. Question the patient concerning valuables, prostheses, and last intake of food and fluid. Validate that the correct preoperative medications were given (if ordered). Provide a pillow or position adjustment if the patient is uncomfortable. Most hospitals require the patient's hair to be covered just before transfer to the OR suite to reduce potential shedding. Specific SCIP measures may include a prophylactic antibiotic started within 30 to 60 minutes before the surgical incision, and application of a warming blanket and SCDs.

NURSING MANAGEMENT PATIENT DURING SURGERY

ROOM PREPARATION

Before transferring the patient into the OR, prepare the room to ensure privacy, prevention of infection, and safety. Individualization of this preparation is essential to achieve the expected patient outcomes. For example, when an obese patient is admitted to the OR, there are several special considerations (see Chapter 41). Ask such questions as, What equipment is needed to safely transfer the patient to and from the OR table? Will extra staff be required for safe transfer and positioning? Is special equipment needed (e.g., extra-long instrumentation)? What special precautions, if any, must be taken to ensure maintenance of the patient's airway? The unique needs of each patient must be addressed for a safe surgical experience.

Surgical attire (pants and shirts, masks, protective eyewear, and caps or hoods) is worn by all people entering the OR (Fig. 19-3). All electrical and mechanical equipment is checked

FIG. 19-3 Surgical attire is worn by all people entering the operating room.

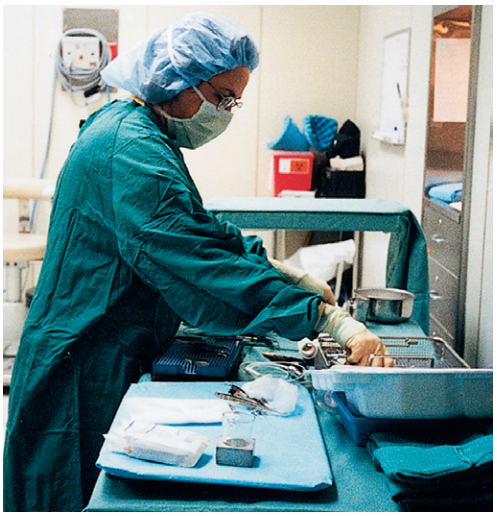

FIG. 19-4 A sterile field is created before surgery.

for proper functioning. Aseptic technique is practiced as each surgical item is opened and placed on the instrument table.[19] Sponges, needles, instruments, and small medical devices (e.g., surgical clip cartridges, universal adapters) are counted according to strict processes to ensure accurate retrieval at the end of the procedure. Any retained surgical supplies, devices, or instruments are sentinel events that can result in negative outcomes for the patient.[20,21]

During room preparation and the surgical procedure, the scrub person performs surgical hand antisepsis, dons sterile gown and gloves, and touches only those items in the sterile field. The circulating nurse remains in the unsterile field and performs those activities that permit touching all unsterile items and the patient. This coordinated effort allows for smooth functioning throughout the procedure.

TRANSFERRING PATIENT

Once the patient's identity has been verified and the OR has been prepared, the patient is transported into the room for the surgery. Each time a patient is transferred from one bed to another, the wheels of the stretcher must be locked, and a sufficient number of personnel should be available to lift, guide, and prevent accidental falling or injury to self, other staff, or the patient. Once the patient is on the OR bed, place safety straps snugly across the patient's thighs. At this time the monitor leads (e.g., electrocardiogram [ECG] leads), BP cuff, and pulse oximeter are usually applied and an IV catheter is inserted if it was not done in the holding area.

SCRUBBING, GOWNING, AND GLOVING

Surgical hand antisepsis is required of all sterile members of the surgical team (scrub nurse, surgeon, and assistant). When the procedure of scrubbing is the chosen method for surgical hand antisepsis (often for the first case of the day), your fingers and hands should be scrubbed first with progression to the forearms and elbows. The hands should be held away from surgical attire and higher than the elbows at all times to prevent contamination from clothing or detergent suds and water from draining from the unclean area above the elbows to the clean and previously scrubbed areas of the hands and fingers.[6,22]

Waterless, alcohol-based agents are replacing traditional soap and water in many facilities. When using an alcohol-based surgical hand-scrub product, prewash hands and forearms with soap and dry completely before applying the alcohol-based product. After application of the alcohol-based product, allow hands and forearms to dry thoroughly before donning sterile gloves.[22,23]

Once surgical hand antisepsis is completed, the team members enter the OR to put on surgical gowns and two pairs of gloves to protect patients and themselves from the transmission of microorganisms.[24,25] Because the gowns and gloves are sterile, those who have scrubbed can manipulate and organize all sterile items for use during the procedure.

BASIC ASEPTIC TECHNIQUE

Aseptic technique is practiced in the OR to prevent infection. This is implemented through the creation and maintenance of a sterile field (Fig. 19-4). The center of the sterile field is the site of the surgical incision. Inanimate items used in the sterile field, including surgical items and equipment, have been sterilized by appropriate sterilization methods.

Team members must understand specific principles to practice aseptic technique (Table 19-3). Unless these principles are followed, the patient's safety is compromised and the potential for postoperative infection is increased.[5,6,19]

In addition to following the principles of aseptic technique, the surgical team is responsible for following the guidelines established by the U.S. Occupational Safety and Health Administration (OSHA) and AORN to protect the patient and the team from exposure to blood-borne pathogens.[26] These guidelines emphasize standard and transmission-based precautions (see eTable 15-1, available on the website for Chapter 15); engineering and work practice controls; and the use of personal protective equipment such as gloves, gowns, caps, face shields, masks, and protective eyewear. This is especially important in the OR because of the high potential for exposure to blood-borne pathogens.

ASSISTING ANESTHESIA CARE PROVIDER

While you check the OR to complete the final preparations, the ACP prepares the patient for the administration of the anesthetic. You need to understand the effects of the anesthetic agents and know the location of all emergency drugs and equipment.

If you are the circulating nurse, you may be involved in placing monitoring devices to be used during the surgical pro-

TABLE 19-3 PRINCIPLES OF ASEPTIC TECHNIQUE IN OPERATING ROOM

- All materials that enter the sterile field must be sterile.
- If a sterile item comes in contact with an unsterile item, it is contaminated.
- Contaminated items are removed immediately from the sterile field. If the unsterile item is small (e.g., unopened suture), once it is removed, the area is marked off (i.e., covered with a sterile drape). If the entire field is contaminated, it should be set up again with all new materials.
- The surgical team working in the operative field must wear sterile gowns and gloves. Once dressed for procedure, they must recognize that the only parts of the gown considered sterile are front from chest to table level and sleeves to 2 inches above elbow.
- A wide margin of safety must be maintained between sterile and unsterile fields.
- Tables are considered sterile only at tabletop level. Items extending beneath this level are considered contaminated.
- The edges of a sterile package are considered contaminated once the package has been opened. If a sterile package (e.g., package of sutures) is placed on the sterile field, that entire package remains sterile even when opened.
- Microorganisms travel on airborne particles and will enter the sterile field with excessive air movements and currents.
- Microorganisms travel by capillary action through moist fabrics, resulting in contamination.
- Microorganisms harbor on the patient's and team members' hair, skin, and respiratory tracts and must be confined by appropriate attire.

cedure (e.g., ECG leads). If the patient is to have a general anesthetic, remain at the patient's side to ensure safety and to assist the ACP. These responsibilities may include measuring BP and assisting in the maintenance of the patient's airway. During the surgical procedure, you also provide a vital communication link for the ACP to other departments such as the laboratory or the blood bank.

SAFETY CONSIDERATIONS

All surgical procedures, regardless of where they take place, can put the patient at risk for injury. These injuries can be infections, physical trauma from positioning or equipment used, or physiologic effects of surgery itself. Be alert to all safety issues, since the patient in the OR is often compromised from the effects of anesthesia.

Fire in the OR can have devastating consequences for the patient. Fortunately, surgical fires can be prevented with awareness of the hazards and emphasis on safe practices.[27] Care must be taken to correctly place the grounding pad and all electrosurgical equipment to prevent injury from burns or fire[28] (Fig. 19-5).

Smoke particles produced during laser procedures may contain trace hydrocarbons (e.g., acetone, isopropanol, formaldehyde, cyanide). These airborne contaminants can cause respiratory irritation and have mutagenic and carcinogenic potential. Smoke evacuators may be used to minimize this exposure.[29]

The *Universal Protocol*, one of the NPSGs, is followed to prevent wrong site, wrong procedure, and wrong surgery.[30] A patient safety checklist for ORs is the cornerstone of a major focus to make surgery safer around the world (see eFig. 19-1 available on the website for this chapter). The use of the World Health Organization (WHO) Surgical Safety Checklist has improved compliance with standards and decreased complications from surgery.[31]

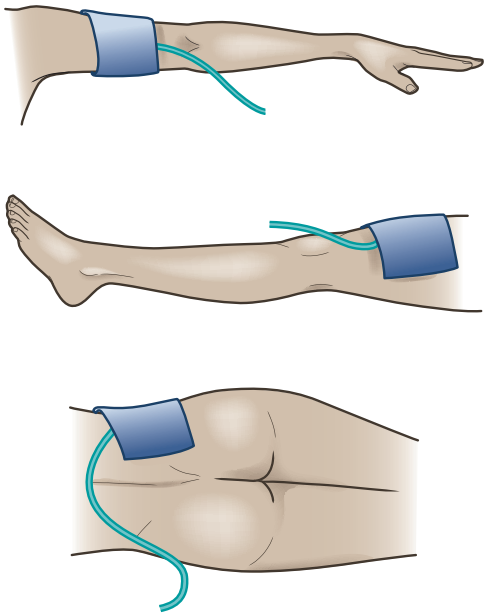

FIG. 19-5 When an electrosurgical unit is used, the patient must be properly grounded to prevent unintended injury. A well-vascularized muscle mass is an optimal site. Safety can be compromised by excessive hair, adipose tissue, bony prominences, fluid (edema), adhesive failure, and scar tissue.

Similarly, AORN has developed a position statement regarding correct site surgery and guidelines for implementing the Universal Protocol.[32] All members of the surgical team stop what they are doing during a *surgical time-out* just before the procedure starts to verify patient identification, surgical procedure, and surgical site. In addition, it is becoming more common for OR personnel to complete a fire risk assessment protocol (see eTable 19-1 available on the website for this chapter) to identify and reduce the potential for an OR fire.

SAFETY ALERT: Take a Surgical Time-Out

- Before the induction of anesthesia, ask the patient to confirm name, birth date, operative procedure and site, and consent.
- Compare the hospital ID number with the patient's own ID band and chart.

POSITIONING PATIENT

Positioning the patient is a critical part of every procedure and usually follows administration of the anesthetic. The ACP indicates when to begin the positioning. The patient's position should allow for accessibility to the operative site, administration and monitoring of anesthetic agents, and maintenance of the patient's airway. When positioning for the surgical procedure, take care to (1) provide correct musculoskeletal alignment; (2) prevent undue pressure on nerves, skin over bony prominences, earlobes, and eyes; (3) provide for adequate thoracic excursion; (4) prevent occlusion of arteries and veins; (5) provide modesty in exposure; and (6) recognize and respect individual needs such as previously assessed aches, pains, or deformities. It is your responsibility to secure the extremities, provide adequate padding and support, and obtain sufficient physical or mechanical help to avoid unnecessary straining of self or patient.[33]

The patient may be placed in various positions, including supine, prone, lateral, lithotomy, or sitting. The supine is the

most common position used. It is suited for surgery involving the abdomen, the heart, and the breast. The prone position allows easy access for back surgery (e.g., laminectomy). The lithotomy position is used for some types of pelvic organ surgery (e.g., vaginal hysterectomy).

Whatever position is required for the procedure, take great care to prevent injury to the patient. Because anesthesia blocks the sensory nerve impulses, the patient will not feel pain or discomfort or stress being placed on nerves, muscles, bones, and skin. Improper positioning could potentially result in muscle strain, joint damage, pressure ulcers, nerve damage, and other untoward effects.

General anesthesia causes peripheral vessels to dilate. Position changes affect where the pooling of blood occurs. If the head of the OR bed is raised, the lower torso will have increased blood volume and the upper torso may become compromised. Hypovolemia and cardiovascular disease can further compromise the patient's status. Consequently, the entire surgical team carefully plans and implements the patient's positioning, and then closely monitors the patient throughout the surgical procedure.

PREVENTING HYPOTHERMIA

Research has shown a correlation between unintended hypothermia and impaired wound healing, adverse cardiac events, altered drug metabolism, and coagulopathies. One study showed that the rate of culture-positive surgical site infections among those with mild perioperative hypothermia was three times higher than among normothermic patients.[34]

To prevent hypothermia, members of the surgical team need to closely monitor the patient's temperature and may apply a thermal warming blanket to the patient to maintain body temperature.[35,36]

PREPARING SURGICAL SITE

The purpose of skin preparation, or "prepping," is to reduce the number of microorganisms available to migrate to the surgical wound. The task of prepping is completed intraoperatively by the circulating nurse, surgeon, or surgical assistant.

The skin is prepared by mechanically scrubbing or cleansing around the surgical site with an antimicrobial agent identified as one that reduces microorganisms on intact skin, contains a nonirritating antimicrobial agent, has broad-spectrum activity, is fast acting and persistent, and is nonallergenic to the patient. A liberal area is scrubbed in a circular motion. The principle of scrubbing from the clean area (site of the incision) to the dirty area (distal to the incision) is observed at all times.[37,38]

Antiseptic agents used for skin preparation may contain alcohol and be flammable. Skin injury can occur if these agents are allowed to pool under the patient. Care must be taken to ensure that these agents are properly confined and allowed to fully dry. After the skin is prepped and the fumes are allowed to dispel, the sterile members of the surgical team drape the area. Only the site to be incised is left exposed.

PATIENT AFTER SURGERY

Through constant observation of the surgical process, the ACP anticipates the end of the surgical procedure. Appropriate types and doses of anesthetic agents are used so that their effects will be minimal at the end of the surgical procedure. This also allows greater physiologic control of the patient during the transfer to the PACU.

The patient's response to your care is evaluated based on outcome criteria established during the development of the patient's plan of care. These outcome criteria are published as the *Perioperative Nursing Data Set (PNDS)* by AORN. The PNDS reflects standards and recommended practices related to the delivery of nursing care in any perioperative setting.[6,39]

The ACP and you or another member of the surgical team accompany the patient to the PACU. A hand-off of the patient that includes his or her status and the procedure performed is communicated to the nurse receiving the patient in the PACU to promote safe, ongoing care.

ANESTHESIA

The art and science of anesthesia have dramatically changed over time. For example, the Bispectral Index monitor allows ACPs to track the level of patient awareness (i.e., *awareness monitoring*) during surgery and adjust sedation as needed. The use of regional anesthetics facilitates the smooth and rapid transition from patient recovery to early discharge.

The anesthetic technique and agents are selected by the ACP in collaboration with the surgeon and the patient. The ACP has ultimate responsibility for the choice of anesthetic. Factors contributing to the decision include the patient's current physical and mental status, allergy and pain history, expertise of the ACP, and factors relating to the operative procedure (e.g., length, site, discharge plans). An absolute contraindication to any anesthetic technique or agent is patient refusal.

The ACP obtains anesthesia consent, writes orders for preoperative and postoperative medications, and assigns the patient an anesthesia classification. The American Society of Anesthesiologists (ASA) physical status classification system is based on the patient's physiologic status with no regard to the surgical procedure to be performed. A scale of P1 to P6 is used, with a rating of P6 reserved for a brain-dead patient undergoing organ harvest (see Table 18-3). An intraoperative complication is more likely to develop with a higher classification number. Other designations can be added to the ASA status (e.g., "E" to designate an "emergent" procedure). ASA physical status is dynamic and represents the patient's status immediately before surgery. For example, a healthy 26-year-old adult who is severely injured in an automobile collision may be classified as ASA P5E because life-threatening injuries require emergent surgery.

CLASSIFICATION OF ANESTHESIA

The ASA classifies anesthesia according to the effect that it has on the patient's sensorium and pain perception. These classifications include general anesthesia, regional anesthesia, local anesthesia, monitored anesthesia care (MAC), and moderate sedation[40,41] (Table 19-4).

Monitored anesthesia care (MAC) is used for diagnostic or therapeutic procedures performed in or outside of the OR (e.g., eye clinic). It includes varying levels of sedation, analgesia, and anxiolysis. A critical component of MAC is the assessment and management of any physiologic problems that may develop. The provider of MAC must be an ACP, since it may be necessary to convert to general anesthesia during the procedure.

Moderate sedation is used for procedures performed outside of the OR (e.g., reduction of dislocated joints in the emergency department) and does not require the presence of an ACP. RNs

TABLE 19-4 CLASSIFICATION OF ANESTHESIA AND PATIENT EFFECTS

Classification	Anticipated Patient Effects
General anesthesia	• Loss of sensation with loss of consciousness • Combination of hypnosis, analgesia, and amnesia • Usually involves use of inhalation agents • Skeletal muscle relaxation • Elimination of coughing, gagging, vomiting, and sympathetic nervous system responsiveness • Requires advanced airway management
Regional anesthesia	• Loss of sensation to a region of body without loss of consciousness • Involves blocking a specific nerve or group of nerves with administration of a local anesthetic • Includes spinal, caudal, and epidural anesthesia and IV and peripheral nerve blocks (e.g., interscalene, axillary, infraclavicular or supraclavicular, popliteal, femoral, sciatic)
Local anesthesia	• Loss of sensation without loss of consciousness • Induced topically or via infiltration, intracutaneously, or subcutaneously • Topical applications may be aerosolized or nebulized
Monitored anesthesia care (MAC)	• Similar to general anesthesia • Sedative, anxiolytic, and/or analgesic medications used • Does not usually involve inhalation agents • Patients less responsive and may require airway management • Provides maximum flexibility to match sedation level to patient needs and procedural requirements • Often used in conjunction with regional or local anesthesia • Often used for minor therapeutic and diagnostic procedures (e.g., eye surgery, colonoscopy)
Moderate sedation (formerly called conscious sedation)	• Sedative, anxiolytic, and/or analgesic medications used • Does not include use of inhalation agents • Patients responsive and breathe without assistance • Not expected to induce levels of sedation that would impair patients' ability to protect their airway • Most often used for minor therapeutic procedures (e.g., realignment of a fracture in the emergency department)

who receive education in moderate sedation and are permitted by institutional protocols and state nurse practice acts can provide this type of anesthesia.[42] It is administered by the nurse under the direct supervision of a physician.

General Anesthesia

The present goals of anesthesiology include the (1) control of excessive biologic responses induced by a variety of stressors and (2) protection of patients from stress-induced complications. To this end, *total intravenous anesthesia (TIVA)* and newer inhalation agents have a fast onset, fast elimination, and fewer undesirable side effects than previous agents. These factors facilitate early discharge from the PACU and ambulatory surgery centers.

General anesthesia is the technique of choice for patients who are having surgical procedures that are of significant duration, require skeletal muscle relaxation, require uncomfortable operative positions because of the location of the incision site, or require control of ventilation. Additional reasons for general anesthesia include refusal of local or regional techniques, contraindications to other techniques, and uncooperative patients. Patients may be uncooperative due to intoxication, emotional lability, head injury, impaired cognition, or inability to remain immobile for any length of time. Phases of general anesthesia are presented in Table 19-5.

General anesthesia may be induced IV or by inhalation, and maintained by either one or a combination of the two (Table 19-6, p. 343). A *balanced technique,* using adjunctive drugs to complement the induction, is the most common approach used for general anesthesia.

Intravenous Agents. Virtually all routine general anesthetics begin with an IV induction agent, whether it is a hypnotic, an anxiolytic, or a dissociative agent. When used during the initial period of anesthesia, these agents induce a pleasant sleep with a rapid onset of action that patients find desirable. A single dose lasts only a few minutes, which is long enough for a laryngeal mask airway (LMA) or an endotracheal (ET) tube to be placed. Once this is done, the ACP uses the selected inhalation and IV agent(s).

Recent advances in IV hypnotics and opioids have led to the more frequent use of TIVA. However, the patient may still require advanced airway management (e.g., LMA, ET tube) and will receive oxygen/air mixtures via this route.

Inhalation Agents. Inhalation agents are the cornerstone of general anesthesia. These agents may be volatile liquids or gases. Volatile liquids are administered through a specially designed vaporizer after being mixed with oxygen as a carrier gas. This gas mixture is then delivered to the patient via the anesthesia circuit. Waste gases are removed using negative evacuation pressure venting to the outside of the institution.

Inhalation agents enter the body through the alveoli in the lungs. Ease of administration and rapid excretion by ventilation make them desirable agents. One undesirable trait is the irritating effect some inhalation agents (e.g., desflurane [Suprane]) have on the respiratory tract. Possible complications include coughing, laryngospasm (muscular constriction of the larynx), and increased secretions.[43]

Once the patient has been induced with an IV agent, the choice for delivering inhalation agents is usually through an ET tube or LMA. The ET tube permits control of ventilation and protects the airway from aspiration. LMAs are currently an important option for patients with difficult airways, but they do not provide access to the trachea with the same certainty as ETs. Complications of ET tube or LMA include those primarily associated with insertion and removal. These include failure to intubate, damage to teeth and lips, laryngospasm, laryngeal edema, postoperative sore throat, and hoarseness caused by injury or irritation of the vocal cords or surrounding tissues.

Adjuncts to General Anesthesia. The administration of general anesthesia is rarely limited to one agent. Drugs added to an inhalation anesthetic (other than an IV induction agent) are termed *adjuncts*. These agents are added to the anesthetic

TABLE 19-5 PHASES OF GENERAL ANESTHESIA

Preinduction	Induction	Maintenance	Emergence
Description			
• Period starting with preoperative medication, initiation of IV or arterial access, application of monitors (e.g., ECG).	• Initiation of medications that make patient unconscious. • Airway secured with airway assist devices.	• Period during which surgical procedure is performed. • Patient remains in an unconscious state with measures to ensure airway safety.	• Period when surgical procedure is completed. • Patient is prepared for return to consciousness and removal of airway assist devices.
Role of Anesthesia Care Provider			
• Determine final anesthetic care plan. • Insert and monitor IV or arterial access. • Confirm antibiotic prophylaxis. • Administer drugs for anxiety, aspiration prophylaxis.	• Administer appropriate drugs. • Secure airway. • Position patient appropriately for surgical procedure.	• Monitor patient's physiologic status. • Administer medications and titrate fluids as appropriate.	• Reverse residual neuromuscular blocking agents. • Assess for return of all protective reflexes. • Remove airway assist devices. • Assess pain.
Role of Perioperative Nurse			
• Complete preoperative assessment. • Check and confirm signed informed consent. • Complete surgical time-out.	• Assist with application of monitors (noninvasive and invasive). • Assist with airway management.	• Adjust patient position as necessary. • Monitor patient safety.	• Assist in placement of dressing. • Protect patient during return of reflexes. • Prepare patient to move to postanesthesia care unit.
Classes of Drugs Used (see Tables 18-9, 19-6, and 19-7)			
• Benzodiazepines • Opioids • Antibiotics • Aspiration prophylaxis: • H_2-receptor blockers (e.g., ranitidine [Zantac]) • Gastric motility agents (e.g., metoclopramide [Reglan]) • Anticholinergics (e.g., scopolamine [Transderm-Scōp])	• Benzodiazepines • Opioids • Barbiturates • Hypnotics • Volatile gases	• Benzodiazepines • Opioids • Barbiturates • Hypnotics • Volatile gases • Neuromuscular blocking agents	• Reversal agents: • Anticholinesterases (e.g., neostigmine [Prostigmin]) • Opioid antagonists (PRN) (e.g., naloxone [Narcan]) • Benzodiazepine antagonists (PRN) (e.g., flumazenil [Romazicon]) • Supplemental opioids (PRN) • Antiemetics (PRN)

regimen specifically to achieve unconsciousness, analgesia, amnesia, muscle relaxation, or autonomic nervous system control. Adjuncts include opioids, benzodiazepines, neuromuscular blocking agents (muscle relaxants), and antiemetics (Table 19-7, p. 344). It is important to know that these drugs are often given in combination and may have synergistic or antagonistic effects. You may observe deeper levels of sedation or more drug-related side effects beyond those seen with inhalation anesthetics alone. If needed, drugs are available to reverse the effects of some of these adjuncts.

Dissociative Anesthesia. Dissociative anesthesia interrupts associative brain pathways while blocking sensory pathways. The patient may appear catatonic, is amnesic, and experiences profound analgesia that lasts into the postoperative period. Ketamine (Ketalar) is a commonly administered dissociative anesthetic. Ketamine (administered IV or intramuscularly) is a potent analgesic and amnesic. It is used in asthmatic patients undergoing surgery because it promotes bronchodilation and in trauma patients requiring surgery because it increases heart rate and helps maintain cardiac output. Because ketamine is a phenylcyclohexylpiperidine (PCP) derivative, the drug may cause hallucinations and nightmares, greatly limiting its usefulness. Concurrent use of midazolam (Versed) can reduce or eliminate hallucinations associated with ketamine. Provide a quiet, unhurried environment in the PACU for all patients receiving dissociative anesthesia.[44]

Local and Regional Anesthesia

Local anesthesia interrupts the generation of nerve impulses by altering the flow of sodium into nerve cells through cell membranes. Volume and concentration of the local anesthetic agent will, in accelerating fashion, first block autonomic, then somatic sensory, and, last, somatic motor impulses. The result is autonomic nervous system blockade, anesthesia, and skeletal muscle flaccidity or paralysis. Local anesthetics are topical, ophthalmic, nebulized, or injectable.

A local anesthetic, such as lidocaine (Xylocaine), is applied to a specific area of the body by the surgeon or ACP and does not require sedation or loss of consciousness. **Regional anesthesia** (or block) using a local anesthetic is always injected and involves a central nerve (e.g., spinal) or group of nerves (e.g., plexus) that innervate a site remote to the point of injection.

Administration of a local or regional anesthetic may involve concurrent use of MAC or moderate sedation (see Table 19-4), either preinjection or intraoperatively. Regional blocks are used as preoperative analgesia, intraoperatively to manage surgical pain, and postoperatively to control pain. Indwelling catheters that deliver local anesthetic via a pump to the surgical site may be implanted before the patient emerges from anesthesia to provide continuous pain relief up to 72 hours postoperatively.

Certain advantages of local and regional anesthesia include rapid recovery and discharge with continued postoperative analgesia and without any accompanying cognitive dysfunc-

TABLE 19-6 DRUG THERAPY

General Anesthesia

Drugs	Advantages	Disadvantages	Nursing Interventions
Intravenous Agents			
Barbiturates			
thiopental (Pentothal) methohexital (Brevital)	Rapid induction, duration of action <5 min.	Adverse cardiac effects (e.g., myocardial depression), hypotension, respiratory depression. *thiopental:* histamine release. *methohexital:* excitation, involuntary movement.	Usually have minimal postoperative effects because of short duration of action. Increased incidence of postoperative nausea in patients with barbiturate sensitivity, histamine-triggered nausea, vomiting.
Nonbarbiturate Hypnotics			
etomidate (Amidate)	Produces little change in cardiovascular dynamics. Useful for hemodynamically unstable patients. Only minor respiratory depression. No histamine release.	Associated with adverse effects of myoclonia, nausea and vomiting, hiccups, and adrenocortical inhibition.	Observe for transient skeletal muscle movements (myoclonia), nausea and vomiting, hiccups, hypotension, hypoglycemia.
propofol (Diprivan)	Ideal for short outpatient procedures because of rapid onset of action, metabolic clearance. May be used for induction and maintenance of anesthesia.	May cause bradycardia and other dysrhythmias, hypotension, apnea, transient phlebitis, nausea and vomiting, hiccups. May cause hypertriglyceridemia.	Monitor for postoperative hypotension, bradycardia. Monitor serum triglycerides q24hr for sedation >24 hr.
Inhalation Agents			
Volatile Liquids			
isoflurane (Forane) desflurane (Suprane) sevoflurane (Ultane) halothane (Fluothane)	All cause skeletal muscle relaxation. *isoflurane*: No increase in ventricular irritability. Does not cause liver or renal toxicity. Resistant to metabolic breakdown. *desflurane*: Fastest onset and emergence, widely used in ambulatory settings. Least postoperative cognitive dysfunction. Potential airway irritant. *sevoflurane*: Predictable effects on cardiovascular and respiratory systems, rapid acting. Preferred for inhalation induction as nonirritating to respiratory tract. *halothane*: Bronchodilation, nonirritating to respiratory tract.	All cause respiratory depression, hypotension, myocardial depression. *isoflurane and desflurane*: May be unsuitable for patients with coronary artery disease. *sevoflurane*: May be associated with emergence delirium (see Chapter 20). Atypical seizure-like activity has been reported. *halothane*: Ventricular excitability, hepatotoxicity.	Assess and treat pain during early anesthesia recovery. Assess for adverse reactions such as cardiopulmonary depression with hypotension and prolonged respiratory depression. Monitor for nausea and vomiting.
Gaseous Agents			
nitrous oxide	Potentiates volatile agents, thus speeding induction and reducing total dosage and side effects. Good analgesic potency. Produces little or no toxicity at therapeutic concentrations.	Weak anesthetic, rarely used alone. Must be administered with O_2 to prevent hypoxemia. Avoid in patients with strong history of nausea and vomiting.	Avoid in patients with bone marrow depression.
Dissociative Anesthetic			
ketamine (Ketalar)	Can be administered IV or IM. Potent analgesic and amnesic.	May cause hallucinations and nightmares, increased intracranial and intraocular pressure, ↑ heart rate, ↑ blood pressure.	Anticipate administration of a benzodiazepine if agitation and hallucinations occur. Calm, quiet environment is essential in postoperative care.

tion.[45] Patients with co-morbidities that would preclude general anesthesia are now offered surgical solutions with increased safety. Some disadvantages to local and regional anesthesia include the potential for technical difficulties; discomfort at the injection site; and the risk of inadvertent vascular injection leading to refractory hypotension, dysrhythmias, and possible seizures. Finally, the inability to precisely match the agent's duration of action to the duration of the surgical procedure is a limiting factor.

In ambulatory or outpatient procedures, you may assist a physician in the administration of a peripheral or regional block. Consequently, you must be familiar with the drugs, the methods of administration, and adverse and toxic effects of the drugs. Initial assessment of the patient should include detailed questioning of the patient's history with local anesthetics and any adverse events associated with their use by the patient or blood relatives.

Many patients report "allergies" to local anesthetics. Although true allergies to local anesthetics occur, they are rare. Allergies are likely to be a result of additives or preservatives in the preparation. Moreover, many local anesthetics are combined with epinephrine solutions. They may be absorbed in the tissues or inadvertently injected IV. Once the agent enters the general circulation, the patient may experience tachycardia, hyperten-

TABLE 19-7 DRUG THERAPY

Adjuncts to General Anesthesia

Agents	Uses During Anesthesia	Adverse Effects	Nursing Interventions
Opioids			
fentanyl (Sublimaze) sufentanil (Sufenta) morphine sulfate hydromorphone (Dilaudid) alfentanil (Alfenta) remifentanil (Ultiva) methadone (Dolophine)	Induce and maintain anesthesia, reduce stimuli from sensory nerve endings, provide analgesia during surgery and recovery in PACU.	Respiratory depression, stimulation of vomiting center, possible bradycardia and peripheral vasodilation (when combined with anesthetics). High incidence of pruritus in both regional and IV administration.	Assess respiratory rate and rhythm, monitor pulse oximetry, protect airway in anticipation of vomiting. Use standing orders for antipruritics and antiemetics. Reverse opioid-induced respiratory depression with naloxone (Narcan). If used, reversal of analgesic effects also occurs.
Benzodiazepines			
midazolam (Versed) diazepam (Valium) lorazepam (Ativan)	Reduce anxiety preoperatively and postoperatively, induce and maintain anesthesia, induce amnesia, treat emergence delirium. Supplement sedation in local and regional anesthesia and MAC.	Synergistic effect with opioids, increasing potential for respiratory depression. Hypotension and tachycardia. Prolonged sedation or confusion.	Monitor level of consciousness. Assess for respiratory depression, hypotension, and tachycardia. Reverse severe benzodiazepine-induced respiratory depression with flumazenil (Romazicon).
Neuromuscular Blocking Agents			
Depolarizing agent: succinylcholine (Anectine)	Facilitate endotracheal intubation, promote skeletal muscle relaxation (paralysis) to enhance access to surgical sites.	Apnea related to paralysis of respiratory muscles. Duration of action of nondepolarizing agents may be longer than surgery. Reversal agents may not completely eliminate effects. Confusion and nausea. Recurrence of muscle weakness with correction of hypothermia.	If intubated, monitor return of muscle strength, level of consciousness, and ventilation. Maintain patent airway. Monitor respiratory rate and rhythm until patient able to cough and return to previous levels of muscle strength. Ensure availability of nondepolarizing reversal agents (e.g., neostigmine [Prostigmin]) and emergency respiratory support equipment. Monitor temperature and levels of muscle strength with temperature changes.
Nondepolarizing agents: vecuronium (Norcuron) pancuronium (Pavulon) pipecuronium (Arduan) doxacurium (Nuromax) rocuronium (Zemuron)	Effects of nondepolarizing agents are usually reversed toward end of surgery by administration of anticholinesterase agents (e.g., neostigmine, pyridostigmine).		
Antiemetics			
ondansetron (Zofran) dolasetron (Anzemet) granisetron (Kytril) metoclopramide (Reglan) prochlorperazine (Compazine) promethazine (Phenergan) scopolamine (Transderm-Scōp) diphenhydramine (Benadryl)	Counteract emetic effects of inhalation agents and opioids. Prophylactic prevention of nausea and vomiting related to histamine release, vagal stimulation, vestibular disturbance, surgical procedure (e.g., abdominal and laparoscopic procedures).	Headache, dizziness, IV irritation, dysrhythmias, dysphoria, dystonia, dry mouth, central nervous system sedation.	Monitor heart rhythm, cardiopulmonary status, level of central nervous system excitation or sedation, ability to move limbs, presence of nausea or vomiting.
Miscellaneous			
dexamethasone (Decadron)	Counteract emetic effects of inhalation agents and opioids (off-label use).*	Insomnia, nervousness, abdominal distention.	Monitor for possible side effects.

*For an explanation of off-label drug use, see *www.cancer.org/docroot/ETO/content/ETO_1_2x_Off-Label_Drug_Use.asp*.
MAC, Monitored anesthesia care; *PACU,* postanesthesia care unit.

sion, and a general perception of panic. There are two classes of local anesthetics: esters and amides. It is highly unlikely that an individual is allergic to both. Therefore it is important to carefully question the patient concerning the agent and the symptoms experienced so that an agent in the proper class can be selected for the procedure.

Methods of Administration. Local anesthetics are injected at the surgical site, nebulized, or applied topically. Topical applications, with or without compression, of creams, ointments, aerosols, and liquids are all standard methods of administration. The agent is applied directly to the skin, mucous membranes, or open surface. Eutectic mixture of local anesthetics (EMLA cream, a combination of prilocaine and lidocaine) is an example of a cream applied to the site 30 to 60 minutes before the procedure for analgesia. The success of injected local anesthetics may be limited by prolonged duration of procedure or infection at the injection site, thus interfering with drug absorption.

Whenever a patient is prepared for regional anesthesia, airway equipment, emergency drugs, and a cardiac monitor/defibrillator should be immediately available to provide advanced airway and cardiopulmonary support if necessary. Inadvertent IV injection of the agent or excessive absorption of bupivacaine (Sensorcaine), in particular, may lead to cardiac depression, severe dysrhythmias, or cardiac arrest.[46]

Examples of common regional nerve blocks include brachial plexus block; IV regional anesthesia (IVRA) or Bier block anesthesia; and femoral, axillary, cervical, sciatic, ankle, and retrobulbar blocks. For IVRA or Bier block, the patient has a

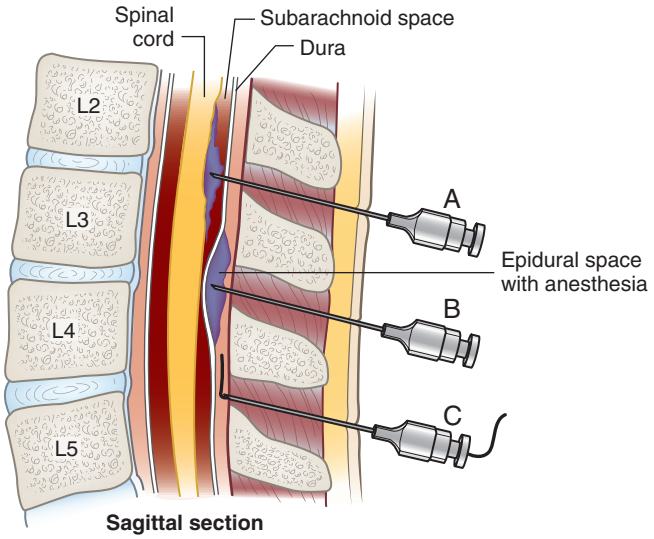

FIG. 19-6 Location of needle point and injected anesthetic relative to dura and spinal cord. **A,** Spinal anesthesia. **B,** Single-injection epidural. **C,** Epidural catheter. (Interspaces most commonly used are L2-3, L4-5, L3-4.)

double-cuff tourniquet applied as a safety measure. You can facilitate the success of regional anesthesia by assisting in patient positioning, monitoring vital signs during block delivery, administering oxygen therapy, and using supporting devices (at the direction of the ACP) that contribute to the anesthesia (e.g., ultrasound imaging, nerve stimulator, tourniquets).

Spinal and Epidural Anesthesia. Spinal anesthesia and epidural anesthesia are also types of regional anesthesia. **Spinal anesthesia** involves the injection of a local anesthetic into the cerebrospinal fluid found in the subarachnoid space, usually below the level of L2 (Fig. 19-6, *A*). The local anesthetic mixes with cerebrospinal fluid. Depending on the extent of its spread, various levels of anesthesia are achieved. Because the local anesthetic is administered directly into the cerebrospinal fluid, a spinal anesthetic produces an autonomic, sensory, and motor blockade. Patients experience vasodilation and may become hypotensive as a result of the autonomic block. They feel no pain as a result of the sensory block. They cannot move as a result of the motor block. The duration of action of the spinal anesthetic depends on the agent selected and the dose administered. A spinal anesthetic may be used for procedures involving the extremities (e.g., joint replacements) and lower gastrointestinal, prostate, and gynecologic surgeries.[47]

An **epidural block** involves injection of a local anesthetic into the epidural space via a thoracic or lumbar approach (see Fig. 19-6, *B*). The anesthetic agent does not enter the cerebrospinal fluid but binds to nerve roots as they enter and exit the spinal cord. With use of a low concentration of local anesthetic, sensory pathways are blocked but motor fibers remain intact. In higher doses, both sensory and motor fibers are blocked. Epidural anesthesia may be used as the sole anesthetic for a surgical procedure. In addition, a catheter may be placed to allow for intraoperative use and continued analgesia in the postoperative period (see Fig. 19-6, *C*). For postoperative analgesia, lower doses of epidurally administered local anesthetic, usually in combination with an opioid, are used.[47] Epidural anesthesia is commonly used for analgesia, or in combination with MAC or general anesthesia, in obstetrics, vascular procedures involving the lower extremities, lung resections, and renal and midabdominal surgeries. The desirable effects of vasodilation and analgesia contribute to better surgical outcomes.[48]

When spinal or epidural anesthesia is used, the patient can remain fully conscious, receive MAC, or choose general anesthesia. The onset of spinal anesthesia is more rapid than that of epidural anesthesia. Both spinal and epidural anesthesia may be extended in duration using indwelling catheters, thus allowing administration of additional doses of anesthetic. Closely observe the patient for signs of autonomic nervous system blockade. These include hypotension, bradycardia, nausea, and vomiting. There is less autonomic nervous system blockade with epidural anesthesia than with spinal anesthesia. Should "too high" a block be achieved, the patient may experience tingling in the arms and hands or inadequate breathing and apnea.[47] Other complications of spinal or epidural anesthesia include postdural puncture headache, back pain, isolated nerve injury, and meningitis.

GERONTOLOGIC CONSIDERATIONS

PATIENT DURING SURGERY

Although anesthetic agents have become safer and more predictable, the aging process affects the pharmacokinetics of drugs, specifically the absorption, distribution, and metabolism of medications. This results in alterations in the onset, peak, and duration of medications independent of the route of administration. Because of this, anesthetic drugs should be carefully titrated when given to older adults. Physiologic changes in aging may alter the patient's response not only to the anesthetic but also to blood and fluid loss and replacement, hypothermia, pain, and tolerance of the surgical procedure and positioning. Carefully monitor the older adult's response to all anesthetic agents. Assess the postoperative recovery from these agents before the patient is transferred out of the PACU.

Some older adults may have difficulty communicating and following directions as a result of alterations in hearing or vision. These factors increase the need for clear and concise communication in the OR, especially when preoperative sedation is combined with already existing sensory deficits. Because of decreased ability to perceive discomfort or pressure on vulnerable areas and a loss of skin elasticity, the older adult's skin is at risk for injury from tape, electrodes, warming and cooling blankets, and certain types of dressings. In addition, pooling of solutions used to prepare the skin in dependent areas can quickly create skin burns or abrasions.

The care and vigilance of the entire surgical team are needed in preparing and positioning the older patient. The older adult often has osteoporosis and osteoarthritis. Misalignment, pressure, or other insults to arthritic joints that may be desensitized from administration of an anesthetic may create long-term injury and disability. Older adults are also at a greater risk of perioperative hypothermia. Consider the use of a variety of warming devices and carefully monitor them if used.

CATASTROPHIC EVENTS IN OPERATING ROOM

Unanticipated intraoperative events occasionally occur. Although some might be anticipated (e.g., cardiac arrest in an unstable patient, massive blood loss during trauma surgery), others may occur without warning, demanding immediate intervention by all members of the OR team. Two such events are anaphylactic reactions and malignant hyperthermia.

Anaphylactic Reactions

Anaphylaxis is the most severe form of an allergic reaction, manifesting with life-threatening pulmonary and circulatory complications. The initial clinical manifestations of anaphylaxis may be masked by anesthesia. ACPs administer an array of drugs to patients, such as anesthetics, antibiotics, blood products, and plasma expanders. Because any parenterally administered material can stimulate an allergic response, vigilance and rapid intervention are essential. An anaphylactic reaction causes hypotension, tachycardia, bronchospasm, and possibly pulmonary edema. Antibiotics and latex are responsible for many perioperative allergic reactions. (Anaphylaxis is discussed in Chapter 14.)

Latex allergy has become a particular concern in the perioperative setting, given the use of gloves, catheters, and many other devices containing natural rubber latex. Reactions to natural rubber latex range from urticaria to anaphylaxis with symptoms appearing immediately or at some time during the surgical procedure. Latex allergy protocols should be set up in each institution to provide a latex-safe environment for susceptible individuals.[49] (Latex allergies are discussed in Chapter 14.)

Malignant Hyperthermia

Malignant hyperthermia (MH) is a rare disorder characterized by hyperthermia with rigidity of skeletal muscles that can result in death. It occurs in susceptible people when they are exposed to certain anesthetic agents. Succinylcholine (Anectine), especially when given with volatile inhalation agents, appears to be the primary trigger of the disorder. Other factors, such as stress, trauma, and heat, also have been implicated. When MH does occur, it is usually during general anesthesia, but it may manifest in the recovery period as well.

MH is an autosomal dominant trait but is variable in its genetic manifestation, so predictions based on family history are important but not reliable. (Autosomal dominant disorders are discussed in Chapter 13.) The fundamental defect is hypermetabolism of skeletal muscle resulting from altered control of intracellular calcium. This leads to muscle contracture, hyperthermia, hypoxemia, lactic acidosis, and hemodynamic and cardiac alterations.

Tachycardia, tachypnea, hypercarbia, and ventricular dysrhythmias are generally seen but are nonspecific to MH. MH is generally diagnosed after all other causes of the hypermetabolism are ruled out. The rise in body temperature is not an early sign of MH. Unless promptly detected and treated, MH can result in cardiac arrest and death. The definitive treatment of MH is prompt administration of dantrolene (Dantrium). Dantrolene slows metabolism, reduces muscle contraction, and mediates the catabolic processes associated with MH.[44] A treatment protocol, available from the Malignant Hyperthermia Association of the United States, is often displayed in the OR[50] (see eFig. 19-2 available on the website for this chapter).

To prevent MH, obtain a careful family history and be alert to the development of MH perioperatively. The patient known or suspected to be at risk for this disorder can be anesthetized with minimal risks if appropriate precautions are taken. Patients with MH should be informed of the condition so that family members may be genetically tested.

FUTURE CONSIDERATIONS

Changes in technology and surgical techniques provide new and better treatment modalities for the patient undergoing surgery. For example, the use of *hypothermia,* or the deliberate lowering of body temperature, decreases metabolism and blood loss. This, in turn, reduces both the demand for oxygen and anesthetic requirements. Neurosurgery and selected trauma surgery benefit from this approach.

Transesophageal echocardiography (TEE) is used intraoperatively to assess ventricular function and competency of heart valves and to recognize venous air embolism. TEE is less invasive, inexpensive, and associated with few complications. It is quickly replacing the use of the pulmonary artery catheter during surgery to assess hemodynamics.

Ultrasonic-guided regional anesthesia is the technique of visualizing a nerve or plexus of nerves using ultrasound to place a regional block with more accuracy. This approach results in fewer side effects and increased patient satisfaction.

Minimally invasive surgery (MIS) is rapidly increasing as more procedures are performed using endoscopes. Incisions are smaller, blood loss is reduced, postoperative pain is decreased, and recovery time is shortened with MIS. Similarly, "bloodless surgery" is becoming more of a reality. Techniques to minimize blood loss during and after surgery include drug therapy and techniques for managing low hematocrit, hemostatic agents to enhance clotting and control bleeding, surgical devices and techniques to locate and stop internal bleeding, and surgical and anesthetic techniques to limit blood loss. The goal is to manage blood loss without the need for a blood transfusion.

Hydroxyethyl starch (Voluven, Hespan) is an IV synthetic starch solution approved for use as a blood volume expander during and after surgery. Blood volume expanders are administered to quickly restore some of the volume lost during surgery so that remaining red blood cells can continue to deliver oxygen to the body's tissues. There are also new alternatives to blood transfusions such as the perioperative use of erythropoietin (epoetin α [Epogen, Procrit]) to increase red blood cell count. Research on the development of a synthetic blood substitute (e.g., PolyHeme) is ongoing.

The number of procedures that can be performed using *robotic-assisted surgery* is rapidly growing. For example, laparoscopic procedures using robotics include prostatectomy, cholecystectomy, common bile duct injury repair, small bowel surgery, tubal reanastomosis, internal mammary artery harvesting, and video-assisted thorascopic surgery.

More recent technologic advancements have made *telesurgery,* or remote surgery, a reality. In telesurgery, a surgeon at a site separate from the patient performs the surgery using a robotic system located at the patient's site. Telesurgery allows surgeons to perform procedures in areas where their expertise is not readily available. In addition, they can perform procedures on patients in remote or hazardous locations (e.g., war zones).

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Proper attire for the semirestricted area of the surgery department is
   a. street clothing.
   b. surgical attire and head cover.
   c. surgical attire, head cover, and mask.
   d. street clothing with the addition of shoe covers.
2. Activities that the nurse might perform in the role of a scrub nurse during surgery include *(select all that apply)*
   a. checking electrical equipment.
   b. preparing the instrument table.
   c. passing instruments to the surgeon and assistants.
   d. coordinating activities occurring in the operating room.
   e. maintaining accurate counts of sponges, needles, and instruments.
3. The nurse is caring for a patient undergoing surgery for a knee replacement. What is critical to the patient's safety during the procedure *(select all that apply)*?
   a. Universal protocol is followed.
   b. The ACP is an anesthesiologist.
   c. The patient has adequate health insurance.
   d. The circulating nurse is a registered nurse.
   e. The patient's allergies are conveyed to the surgical team.
4. The nurse's primary responsibility for the care of the patient undergoing surgery is
   a. developing an individualized plan of nursing care for the patient.
   b. carrying out specific tasks related to surgical policies and procedures.
   c. ensuring that the patient has been assessed for safe administration of anesthesia.
   d. performing a preoperative history and physical assessment to identify patient needs.
5. When scrubbing at the scrub sink, the nurse should
   a. scrub from elbows to hands.
   b. scrub without mechanical friction.
   c. scrub for a minimum of 10 minutes.
   d. hold the hands higher than the elbows.
6. When positioning a patient in preparation for surgery, the nurse understands that injury to the patient is most likely to occur as a result of
   a. incorrect musculoskeletal alignment.
   b. loss of perception of pain or pressure.
   c. pooling of blood in peripheral vessels.
   d. disregarding the patient's need for modesty.
7. Intravenous induction for general anesthesia is the method of choice for most patients because
   a. the patient is not intubated.
   b. the agents are nonexplosive.
   c. induction is rapid and pleasant.
   d. emergence is longer but with fewer complications.

1. b, 2. b, c, e, 3. a, e, 4. a, 5. d, 6. a, 7. c

LEARNING OUTCOMES

1. Prioritize nursing responsibilities in admitting patients to the postanesthesia care unit (PACU).
2. Prioritize nursing responsibilities in the prevention of postoperative complications of patients in the PACU.
3. Apply data from the initial nursing assessment to the management of the patient after transfer from the PACU to the general care unit.
4. Select appropriate nursing interventions to manage potential problems during the postoperative period.
5. Differentiate discharge criteria from Phase I and Phase II postanesthesia care.

fast-tracking, p. 349
patient-controlled analgesia (PCA), p. 358
postoperative ileus, p. 359
rapid postanesthesia care unit progression (RPP), p. 349

The postoperative period begins immediately after surgery and continues until the patient is discharged from medical care. This chapter focuses on the common features of postoperative nursing care of the surgical patient. Specific surgical procedures are discussed in the appropriate chapters of this text.

POSTOPERATIVE CARE OF THE SURGICAL PATIENT

The patient's immediate recovery period is managed in a *postanesthesia care unit (PACU),* which is located adjacent to the operating room (OR). This location minimizes transportation of the patient immediately after surgery and provides ready access to anesthesia and OR personnel. During the three phases of postanesthesia care, different levels of care are provided depending on the patient's needs[1] (Table 20-1).

Postanesthesia Care Unit Admission

The patient's initial admission to the PACU is a joint effort among the anesthesia care provider (ACP), the OR nurse, and the PACU nurse. This collaborative effort fosters a smooth transfer of care to the PACU and helps determine the phase to which the patient is assigned.

PACU Progression. How patients move through the phases of care in the PACU is determined by their condition. If a patient assigned to Phase I care on admission to the PACU is stable and recovering well, the patient may rapidly progress through Phase I to discharge to either Phase II care or an inpatient unit. This accelerated progress is called **rapid postanesthesia care unit progression (RPP).** Another accelerated system of care is **fast-tracking,** which involves admitting ambulatory surgery patients directly to Phase II care.[1] Although both RPP and fast-tracking can potentially result in time and cost savings, the patient's safety is the primary

determining factor of where and at what level postoperative care is provided.[2,3]

Phase I Initial Assessment. On admission of the patient to the PACU, the ACP gives you a complete postanesthesia admission report (Table 20-2). The goal of PACU care is to identify actual and potential patient problems that may occur as a result of anesthesia and surgery and to intervene appropriately. Potential problems in the postoperative period are identified in Fig. 20-1. Table 20-3 identifies key components of a PACU assessment.

Begin the assessment with an evaluation of the patient's airway, breathing, and circulation (ABC) status. During the initial assessment, identify signs of inadequate oxygenation and ventilation (Table 20-4). Any evidence of respiratory compromise requires prompt intervention.

Pulse oximetry monitoring provides a noninvasive means of assessing oxygenation and can provide an early warning of hypoxemia.[4] *Transcutaneous carbon dioxide ($PTCCO_2$)* and *end-tidal CO_2 ($PETCO_2$) (capnography) monitoring* are used to detect respiratory depression.[5-6] (Pulse oximetry, $PTCCO_2$, and $PETCO_2$ are discussed in Chapter 26.)

Note and evaluate deviations in electrocardiographic (ECG) results from preoperative findings. Measure the blood pressure (BP) and compare it with baseline readings. Invasive monitoring (e.g., arterial BP) is initiated if needed. Also assess body temperature, capillary refill, and skin condition (e.g., color, moisture). Any evidence of inadequate circulatory status requires prompt intervention.

The initial neurologic assessment focuses on level of consciousness; orientation; sensory and motor status; and size, equality, and reactivity of the pupils. The patient may be awake, drowsy but arousable, or asleep. Because hearing is the first sense to return in the unconscious patient, explain all activities to the patient from the moment of admission to the PACU. If the patient received a regional anesthetic (e.g., spinal, epidural), sensory and motor blockade may still be present and a

dermatome level should be checked (see eFig. 9-1). (A dermatome is an area of the skin that is supplied by a single spinal nerve.) During recovery from regional anesthesia, sensory and motor function returns from the extremities to the site where the anesthetic was administered. Therefore the areas near the site of injections are the last to recover.

Assessment of the urinary system focuses on intake, output, and fluid balance. Intraoperative fluid totals are part of the anesthesia report. Note the presence of all IV lines; all irrigation solutions and infusions; and all output devices, including catheters and wound drains. Assess the surgical site, noting the condition of any dressings and the type and amount of any drainage. Implement postoperative orders related to incision care.

Nursing management of these problems is discussed in the following pages and can be applied to patients in both the PACU and the clinical unit.

RESPIRATORY PROBLEMS

Etiology

PACU. In the immediate postanesthesia period the most common causes of airway compromise include obstruction, hypoxemia, and hypoventilation (Table 20-5). Patients at high risk include those who have had general anesthesia; are older; have a smoking history; have obstructive sleep apnea or lung disease; are obese; or have undergone airway, thoracic, or abdominal surgery. However, respiratory problems may occur with any patient who has been anesthetized.

Airway obstruction is commonly caused by blockage of the airway by the patient's tongue (Fig. 20-2). The base of the tongue falls backward against the soft palate and occludes the pharynx. It is most pronounced in the supine position and in the patient who is extremely sleepy after surgery.

Hypoxemia, a partial pressure of arterial oxygen (PaO_2) less than 60 mm Hg, is characterized by a variety of nonspecific clinical signs and symptoms, ranging from agitation to somnolence, hypertension to hypotension, and tachycardia to bradycardia. Pulse oximetry will indicate low O_2 saturation (less than 90% to 92%).

The most common cause of postoperative hypoxemia is atelectasis. **Atelectasis** (alveolar collapse) may be the result of bronchial obstruction caused by retained secretions or decreased respiratory excursion. Atelectasis may also result from general anesthesia. Atelectasis occurs when mucus blocks bronchioles or when the amount of alveolar surfactant (the substance that holds the alveoli open) is reduced (Fig. 20-3). As air becomes trapped beyond the plug and is eventually absorbed, the alveoli collapse. Atelectasis may affect a portion of or an entire lobe of the lungs.

Other causes of hypoxemia include pulmonary edema, pulmonary embolism (PE), aspiration, and bronchospasm.

TABLE 20-5 POSTOPERATIVE RESPIRATORY COMPLICATIONS

Complications	Mechanisms	Manifestations	Interventions
Airway Obstruction			
Tongue falling back	Muscular flaccidity associated with ↓ consciousness and muscle relaxants	Use of accessory muscles Snoring respirations ↓ Air movement	Patient stimulation Head tilt, jaw thrust (see Fig. 20-2) Artificial airway
Retained thick secretions	Secretion stimulation by anesthetic agents Dehydration of secretions	Noisy respirations Coarse crackles	Suctioning Deep breathing and coughing IV hydration Chest physical therapy
Laryngospasm	Irritation from endotracheal tube, anesthetic gases, or gastric aspiration Most likely to occur after removal of endotracheal tube	Inspiratory stridor (crowing respirations) Sternal retraction Acute respiratory distress	O_2 therapy Positive pressure ventilation IV muscle relaxant Lidocaine Corticosteroids
Laryngeal edema	Allergic drug reaction Mechanical irritation from intubation Fluid overload	Similar to laryngospasm	O_2 therapy Antihistamines Corticosteroids Sedatives Possible intubation
Hypoxemia			
Atelectasis	Bronchial obstruction caused by retained secretions or ↓ lung volumes	↓ Breath sounds ↓ O_2 saturation	Humidified O_2 therapy Deep breathing Incentive spirometry Early mobilization
Pulmonary edema	Fluid overload ↑ Hydrostatic pressure ↓ Interstitial pressure ↑ Capillary permeability	↓ O_2 saturation Crackles Infiltrates on chest x-ray	O_2 therapy Diuretics Fluid restriction
Pulmonary embolism	Thrombus dislodged from peripheral venous system and lodged in pulmonary arterial system	Acute tachypnea Dyspnea Tachycardia Hypotension ↓ O_2 saturation Bronchospasm	O_2 therapy Cardiopulmonary support Anticoagulant therapy
Aspiration	Inhalation of gastric contents into lungs	Unexplained tachypnea Bronchospasm ↓ O_2 saturation Atelectasis Interstitial edema Alveolar hemorrhage Respiratory failure	O_2 therapy Cardiac support Antibiotics
Bronchospasm	↑ Smooth muscle tone with closure of small airways	Wheezing Dyspnea Tachypnea ↓ O_2 saturation	O_2 therapy Bronchodilators
Hypoventilation			
Depression of central respiratory drive	Medullary depression from anesthetics, opioids, sedatives	Shallow respirations ↓ Respiratory rate, apnea ↓ PaO_2 ↑ $PaCO_2$	Stimulation Reversal of opioids or benzodiazepines Mechanical ventilation
Poor respiratory muscle tone	Neuromuscular blockade Neuromuscular disease	As above	Reversal of paralysis Mechanical ventilation
Mechanical restriction	Tight casts, dressings, abdominal binders. Positioning and obesity preventing lung expansion	As above	Elevate head of bed Repositioning Loosen dressings
Pain	Shallow breathing to prevent incisional pain	↑ Respiratory rate Hypotension Hypertension ↓ $PaCO_2$ ↓ PaO_2 Complaints of pain Guarding behavior	Opioid analgesic drug therapy Nonsteroidal antiinflammatory drug therapy Adjunctive complementary and alternative therapies (e.g., music therapy, guided imagery)

$PaCO_2$, Partial pressure of arterial carbon dioxide; *PaO_2*, partial pressure of arterial oxygen.

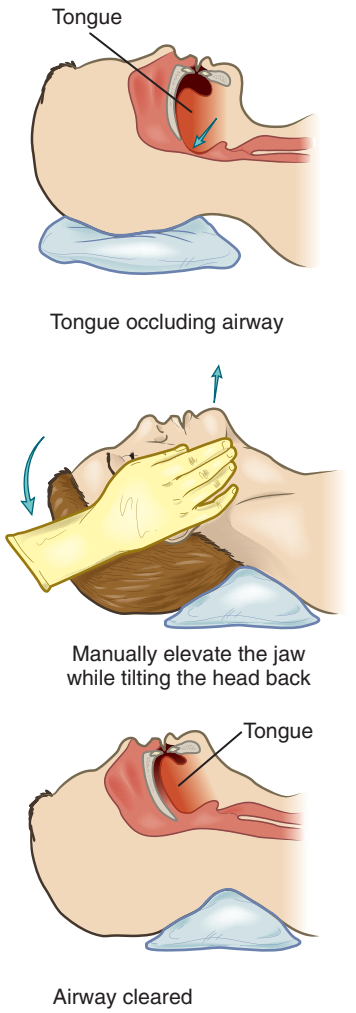

FIG. 20-2 Etiology and relief of airway obstruction.

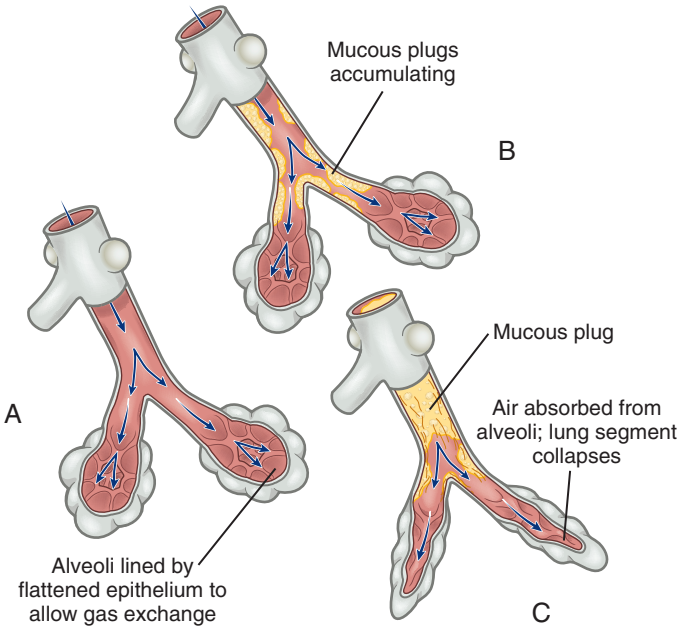

FIG. 20-3 Postoperative atelectasis. **A,** Normal bronchiole and alveoli. **B,** Mucous plug in bronchiole. **C,** Collapse of alveoli resulting from atelectasis after absorption of air.

Pulmonary edema is caused by an accumulation of fluid in the alveoli. It may be the result of fluid overload, left ventricular failure, prolonged airway obstruction, sepsis, or aspiration.

Aspiration of gastric contents into the lungs is a potentially serious emergency. Gastric aspiration may also cause laryngospasm, infection, and pulmonary edema. Because of the serious consequences of aspiration of gastric fluids, prevention is the goal.

Bronchospasm is the result of an increase in bronchial smooth muscle tone with resultant closure of small airways. Airway edema develops, causing secretions to build up in the airway. The patient will have wheezing, dyspnea, use of accessory muscles, hypoxemia, and tachypnea. Bronchospasm may be due to aspiration, endotracheal intubation, suctioning, or an allergic response. (Allergic responses are discussed in Chapter 14.) Bronchospasm may occur in any patient but is seen more frequently in patients with asthma and chronic obstructive pulmonary disease (COPD).

Hypoventilation, a common complication in the PACU, is characterized by a decreased respiratory rate or effort, hypoxemia, and an increasing partial pressure of arterial carbon dioxide ($PaCO_2$) *(hypercapnia).* Hypoventilation may result from depression of the central respiratory drive (secondary to anesthesia or pain medication), poor respiratory muscle tone (secondary to neuromuscular blockade or disease), or a combination of both.

Clinical Unit. Common causes of respiratory problems for postoperative patients in the clinical unit are atelectasis and pneumonia, especially after abdominal and thoracic surgery. The postoperative development of mucous plugs and decreased surfactant production is directly related to hypoventilation, immobility and bed rest, ineffective coughing, and history of smoking. Increased bronchial secretions occur when the respiratory passages have been irritated by heavy smoking; acute or chronic pulmonary infection or disease; and the drying of mucous membranes that occurs with intubation, inhalation anesthesia, and dehydration. Without intervention, atelectasis can progress to pneumonia.

NURSING MANAGEMENT RESPIRATORY PROBLEMS

NURSING ASSESSMENT

For an adequate respiratory assessment, evaluate airway patency; chest symmetry; and the depth, rate, and character of respirations. Observe the chest wall for symmetry of movement. Impaired ventilation may initially be seen as slowed breathing or reduced chest and abdominal movement during breathing. Also assess for the use of abdominal or accessory muscles, which may indicate respiratory distress. Auscultate breath sounds, since decreased or absent breath sounds are found when airflow is diminished or obstructed.

Regular monitoring of vital signs, including pulse oximetry, and a thorough respiratory assessment permit you to recognize early signs of respiratory problems. Manifestations of hypoxemia include tachypnea, gasping, anxiety, restlessness, confusion, and a rapid or thready pulse.

Note and record the characteristics of sputum or mucus. Mucus from the trachea and throat is normally colorless and thin in consistency. Sputum from the lungs and bronchi is normally thick with a pale yellow tinge. Changes in sputum (e.g., color) may indicate a respiratory infection.

DELEGATION DECISIONS

Postoperative Patient

In the PACU, patients require frequent assessment and intervention by RNs. On the clinical units, the RN is responsible for assessment, development of an individualized plan of care, evaluation of the patient, and discharge teaching. Much of the care can be delegated to LPN/LVNs and UAP.

PACU	Clinical Unit
Registered Nurse (RN)	
• Assess patient's initial airway, breathing, and circulation status. • Evaluate for the return to consciousness, ability to maintain airway and breathing. • Provide ongoing assessments for postoperative problems (e.g., airway obstruction, hypoventilation, hypotension or hypertension, dysrhythmias, emergence delirium). • Evaluate patient's readiness to transfer to the clinical unit or be discharged from ambulatory surgery. • Provide oral and written report about patient status when transferring patient to RN on the clinical unit. • Provide discharge teaching for patient and caregiver after ambulatory surgery.	• Assess patient on initial admission to the clinical unit. • Assess for postoperative complications (e.g., atelectasis, hemodynamic instability, cognitive dysfunction, pain, fluid and electrolyte disturbance, fever or hypothermia, nausea and vomiting, urinary retention, wound infection). • Develop an individualized plan of care based on identification of patient risk factors and potential complications. • Develop and implement individualized patient and caregiver education, including discharge teaching.
Licensed Practical/Vocational Nurse (LPN/LVN)	
• Administer and titrate O_2 based on agency protocols. • Administer analgesics and IV fluids (consider state nurse practice act and agency policy).	• Titrate O_2 administration according to prescribed parameters. • Monitor pain level and administer prescribed analgesics. • Administer medications (consider state nurse practice act and agency policy for medications). • Provide wound care, including dressing changes. • Use bladder ultrasound to check for urinary retention. • Insert catheter as prescribed for urinary retention.
Unlicensed Assistive Personnel (UAP)	
• Assist with positioning of patients in the "recovery" position. • Obtain vital signs and pulse oximetry; report abnormal levels to RN. • Assist patient with elimination needs. • Assist in transfer of patient to clinical unit.	• Monitor vital signs, pulse oximetry, and intake and output. Report abnormal levels to RN. • Assist patient with deep breathing and coughing exercises. • Report complaints of pain to RN or LPN/LVN. • Reposition and ambulate patients. • Provide hygiene, including oral care. • Assist with nutrition and elimination needs.

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems related to respiratory problems include, but are not limited to, the following:

- Ineffective airway clearance *related to* ineffective cough, obstruction, pain
- Ineffective breathing pattern *related to* anesthetic agents, pain
- Impaired gas exchange *related to* hypoventilation
- Risk for aspiration
- Potential complication: pneumonia
- Potential complication: atelectasis

NURSING IMPLEMENTATION

In the PACU, nursing interventions are designed to prevent and treat respiratory problems. Proper positioning of the patient facilitates respirations and protects the airway.

SAFETY ALERT

- Position the unconscious patient in a lateral "recovery" position (Fig. 20-4) to keep the airway open and reduce the risk of aspiration if vomiting occurs.

Once conscious, the patient is usually returned to a supine position with the head of the bed elevated. This position maximizes expansion of the thorax by decreasing the pressure of the abdominal contents on the diaphragm.

Oxygen therapy is used if the patient has had general anesthesia or if ordered. Oxygen is given via nasal cannula or face mask. The oxygen aids in the elimination of anesthetic gases and helps meet the increased demand for oxygen resulting from decreased blood volume or increased cellular metabolism.

Deep breathing is encouraged to aid gas exchange and to promote the return to consciousness. Once the patient is more awake, deep-breathing and coughing techniques help prevent alveolar collapse and move respiratory secretions to larger airway passages for expectoration. One technique, known as *sustained maximal inspiration,* requires the patient to inhale as deeply as possible and, at the peak of inspiration, hold the breath for a few seconds, and then exhale. This should be followed by a second deep breath and cough. The use of an incentive spirometer helps by providing visual feedback of respiratory effort (Fig. 20-5). Diaphragmatic or abdominal breathing involves inhaling slowly and deeply through the nose, holding the breath for a few seconds, and then exhaling slowly and completely through the mouth. The patient's hands should be placed lightly over the lower ribs and upper abdomen so the patient can feel the abdomen rise during inspiration and fall during expiration. Unless contraindicated, encourage the patient to perform these maneuvers 10 times every hour while awake.

Effective coughing is essential in mobilizing secretions. If secretions are in the respiratory tract, deep breathing often moves them up and stimulates the cough reflex. Splinting an abdominal incision with a pillow or a rolled blanket supports

FIG. 20-4 Position of patient during recovery from general anesthesia.

FIG. 20-5 Proper use of an incentive spirometer.

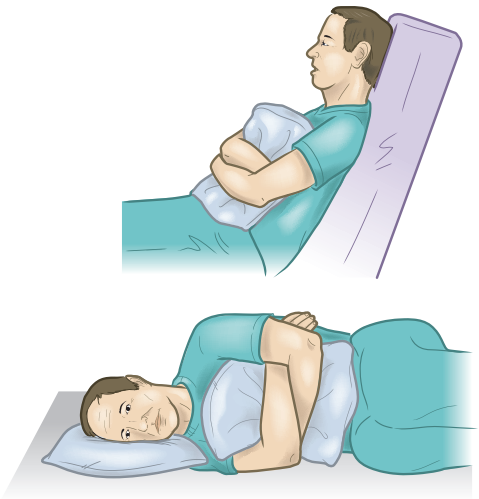

FIG. 20-6 Techniques for splinting incision when coughing.

the incision and aids in coughing and expectorating secretions (Fig. 20-6).

Change the patient's position every 1 to 2 hours to allow full chest expansion and to increase perfusion of both lungs. Sitting in a chair and ambulating should be carried out as soon as physician approval is given. Provide adequate and regular analgesic medication because incisional pain often is the greatest barrier to patient participation in effective breathing exercises and ambulation. Also reassure the patient that these activities will not cause the incision to open. Adequate hydration, either parenteral or oral, is essential to maintain the integrity of mucous membranes and to keep secretions thin and loose for easy expectoration.

Other nursing interventions appropriate for specific respiratory problems are detailed in Table 20-5. A nursing care plan for the postoperative patient (eNursing Care Plan 20-1) is available on the website for this chapter.

CARDIOVASCULAR PROBLEMS

Etiology

PACU. In the immediate postanesthesia period the most common cardiovascular problems include hypotension, hypertension, and dysrhythmias. Patients at greatest risk for alterations in cardiovascular function include those with alterations in respiratory function, those with a history of cardiovascular disease, older adults, the debilitated, and the critically ill.

Hypotension is evidenced by signs of hypoperfusion to the vital organs, especially the brain, heart, and kidneys. Clinical signs of disorientation, loss of consciousness, chest pain, and oliguria reflect hypoperfusion, hypoxemia, and the loss of physiologic compensation. Intervention must be timely to prevent the devastating complications of cardiac ischemia or infarction, cerebral ischemia, renal ischemia, and bowel infarction.

The most common cause of hypotension in the PACU is unreplaced fluid and blood loss, which may lead to hypovolemic shock. Hemorrhage is always a risk of surgery. Marked blood loss is possible when cauterization or sutures fail. Hemorrhage most often occurs internally, requiring assessment for changes in level of consciousness and vital signs. If changes are detected, treatment is directed toward restoring circulating volume. If there is no response to fluid administration, cardiac dysfunction should be considered the cause of hypotension.

Primary cardiac dysfunction, as may occur in myocardial infarction, cardiac tamponade, or PE, results in an acute fall in cardiac output. Secondary myocardial dysfunction occurs as a result of the negative *chronotropic* (rate of cardiac contraction) and negative *inotropic* (force of cardiac contraction) effects of drugs, such as β-adrenergic blockers, digoxin, or opioids. Other causes of hypotension include decreased systemic vascular resistance, dysrhythmias, and measurement errors (e.g., taking BP with an incorrectly sized cuff).

Hypertension, a common finding in the PACU, is most frequently the result of sympathetic nervous system stimulation that may be the result of pain, anxiety, bladder distention, or respiratory compromise. Hypertension may also be the result of hypothermia and preexisting hypertension.

In the PACU, *dysrhythmias* are caused by hypoxemia, hypercapnia, alterations in electrolyte and acid-base status, circulatory instability, and preexisting heart disease. Hypothermia, pain, surgical stress, and many anesthetic agents can also cause dysrhythmias.

Clinical Unit. In the clinical unit, postoperative fluid and electrolyte imbalances are contributing factors to cardiovascular problems. Such imbalances may result from a combination of the body's normal response to the stress of surgery, excessive fluid losses, and improper IV fluid replacement. The body's fluid status directly affects cardiac output.

Fluid retention during postoperative days 1 to 3 can result from the stress response, which serves to maintain both blood volume and BP. Fluid retention is caused by the secretion and release of two hormones by the pituitary—antidiuretic hormone (ADH) and adrenocorticotropic hormone (ACTH)—and activation of the renin-angiotensin-aldosterone system (RAAS). ADH release leads to increased water reabsorption and decreased urine output, increasing blood volume. ACTH stimulates the adrenal cortex to secrete cortisol and, to a lesser degree, aldosterone. Fluid losses resulting from surgery decrease kidney perfusion, stimulating the RAAS and causing marked release of aldosterone (see Chapter 17). Both mechanisms that increase aldosterone lead to significant sodium and fluid retention, thus increasing blood volume.

Fluid overload may occur during this period of fluid retention when IV fluids are administered too rapidly, when chronic (e.g., cardiac, renal) disease exists, or when the patient is an older adult. Fluid deficits from untreated preoperative dehydration, intraoperative blood losses, or slow or inadequate fluid

replacement can lead to decreases in cardiac output and tissue perfusion. Postoperative losses from vomiting, bleeding, wound drainage, or suctioning can also contribute to fluid deficits.

Hypokalemia can be a consequence of urinary and gastrointestinal (GI) tract losses. Low serum potassium levels directly affect the contractility of the heart and may contribute to decreases in cardiac output and tissue perfusion. Potassium replacement, usually 40 mEq/day, should not be given until renal function is assessed. A urine output of at least 0.5 mL/kg/hr is generally considered indicative of adequate renal function.

Cardiovascular status is also affected by the state of tissue perfusion or blood flow. The stress response contributes to an increase in clotting tendencies by increasing platelet production. In addition, general anesthesia causes peripheral vasodilation, which may contribute to damage of the vascular lining.

A *venous thromboembolism* (VTE) may form in leg veins as a result of inactivity, body position, and pressure, all of which lead to venous stasis and decreased perfusion. VTE is especially common in older adults, obese individuals, immobilized patients, and patients with a history of PE. It is a potentially life-threatening complication because it may lead to PE and infarction. Suspect PE in any patient with tachypnea, dyspnea, and tachycardia, particularly when the patient is already receiving O_2 therapy. Other manifestations may include agitation, chest pain, hypotension, hemoptysis, dysrhythmias, and heart failure. Superficial thrombophlebitis is an uncomfortable but less serious complication that may develop in a leg vein as a result of venous stasis or in the arm veins as a result of irritation from IV catheters or solutions. (PE and VTE are discussed in Chapters 28 and 38, respectively.)

Syncope (fainting) may indicate decreased cardiac output, fluid deficits, or defects in cerebral perfusion. Syncope frequently occurs as a result of postural hypotension when the patient ambulates. It is more common in the older adult or in the patient who has been immobile for long periods. Normally when the patient stands up quickly, the arterial baroreceptors respond to the accompanying fall in BP with sympathetic nervous system stimulation. This produces vasoconstriction and thereby maintains BP. These sympathetic and vasomotor functions may be diminished in the older adult and the immobile or postanesthesia patient.

NURSING MANAGEMENT CARDIOVASCULAR PROBLEMS

NURSING ASSESSMENT

The most important aspect of the cardiovascular assessment is frequent monitoring of vital signs. They are usually monitored every 15 minutes in Phase I, or more often until stabilized, and then at less frequent intervals in Phase II. Compare postoperative vital signs with preoperative and intraoperative readings to determine when the signs are returning to baseline. Notify the ACP or the surgeon if any of the following occurs:

- Systolic BP less than 90 mm Hg or greater than 160 mm Hg
- Pulse rate less than 60 beats/minute or greater than 120 beats/minute
- Pulse pressure (difference between systolic and diastolic pressures) narrows
- BP trends gradually decrease over several consecutive readings
- Change in cardiac rhythm

ECG monitoring is recommended for patients who have a history of cardiac disease and for all older adult patients who have undergone major surgery, regardless of whether they have cardiac problems. Assess the apical-radial pulse carefully, and report any deficits or irregularities.

Assessment of skin color, temperature, and moisture provides valuable information in detecting cardiovascular problems. Hypotension accompanied by a normal pulse and warm, dry, pink skin usually represents the residual vasodilating effects of anesthesia and suggests only a need for continued observation. Hypotension accompanied by a rapid or weak pulse and cold, clammy, pale skin may indicate impending hypovolemic shock and requires immediate treatment.

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems related to cardiovascular problems include, but are not limited to, the following:

- Decreased cardiac output *related to* hypovolemia, dysrhythmias
- Ineffective peripheral tissue perfusion *related to* prolonged immobility, venous stasis
- Risk for imbalanced fluid volume
- Potential complication: hypovolemic shock
- Potential complication: venous thromboembolism

NURSING IMPLEMENTATION

PACU. Treatment of hypotension should always begin with O_2 therapy to promote oxygenation of hypoperfused organs. Inspect the surgical incision to determine if excessive bleeding is the cause of volume loss. Because the most common cause of hypotension is fluid loss, IV fluid boluses are given to normalize BP. Primary cardiac dysfunction may require drug intervention. Peripheral vasodilation and hypotension may require vasoconstrictive agents to increase systemic vascular resistance.

Treatment of hypertension centers on eliminating the cause of sympathetic nervous system stimulation. Treatment may include the use of analgesics, assistance in voiding, and correction of respiratory problems. Rewarming corrects hypothermia-induced hypertension. If the patient has preexisting hypertension or has undergone cardiac or vascular surgery, drug therapy to reduce BP is usually required.

Because the majority of dysrhythmias seen in the PACU have identifiable causes, treatment is directed toward removing the cause. Correction of these physiologic alterations usually corrects the dysrhythmias. In the event of life-threatening dysrhythmias (e.g., ventricular tachycardia), protocols for advanced cardiac life support are followed.

CLINICAL UNIT. Maintaining an accurate intake and output record, monitoring laboratory findings (e.g., electrolytes, hematocrit), and managing IV therapy are key nursing responsibilities during the postoperative period. Ongoing assessment of the potential complications associated with IV potassium, such as cardiac dysrhythmias and pain at the infusion site, is essential.

Early ambulation is the most significant general nursing measure to prevent postoperative complications. The exercise associated with walking (1) increases muscle tone; (2) stimulates circulation, which prevents venous stasis and VTE, and speeds wound healing; and (3) increases vital capacity and maintains normal respiratory function.

Recommendations for the prevention of VTE for patients who undergo a major surgical procedure or who have multiple

risk factors for VTE (e.g., nonambulatory, older, history of VTE) include prophylaxis with low-molecular-weight heparin (LMWH) (e.g., dalteparin [Fragmin], enoxaparin [Lovenox]) or low-dose unfractionated heparin. In addition, sequential compression devices (SCDs) are often used in combination with drug prophylaxis.[7] (SCDs are discussed in Chapter 38.)

You can prevent syncope by slowly making changes in the patient's position. Progression to ambulation can be achieved by first raising the head of the patient's bed for 1 to 2 minutes and then assisting the patient to sit, with legs dangling, while monitoring the pulse rate. If no changes or complaints are noted, start ambulation with ongoing monitoring of the pulse. If changes in the pulse are noted or dizziness occurs, sit the patient in a nearby chair. The patient should remain in this location until the BP and pulse are stable. Then help the patient back to the bed. If dizziness occurs, it is often frightening for the patient and you. Injury can result from a fall, so take measures to ensure patient safety.

NEUROLOGIC AND PSYCHOLOGIC PROBLEMS

Etiology

PACU. Postoperatively, **emergence delirium,** or *waking up wild,* is the neurologic alteration that causes the most concern. It is manifested by behaviors such as restlessness, agitation, disorientation, thrashing, and shouting. This condition may be caused by hypoxia, anesthetic agents, bladder distention, pain, residual neuromuscular blockade, or the presence of an endotracheal tube.[8] If delirium occurs, first suspect hypoxia.

Delayed emergence may also be a problem postoperatively. Fortunately, the most common cause of delayed emergence is prolonged drug action, particularly of opioids, sedatives, and inhalation anesthetics, as opposed to neurologic injury. Normal awakening can be predicted by the ACP based on the drugs used in surgery.

Clinical Unit. Two types of postoperative cognitive impairments seen in surgical patients are *postoperative cognitive dysfunction* (POCD) and *delirium.* POCD is a decline in the patient's cognitive function (e.g., memory, ability to concentrate) for weeks or months after surgery. POCD is primarily seen in the older surgical patient. Preexisting cognitive impairment, age, duration of anesthesia, intraoperative complications, and postoperative infections are related to the development of POCD.[9]

Postoperative delirium is more common in the older patient, but it can occur in patients of any age. Delirium may be the result of severe postoperative pain, fluid and electrolyte imbalances, hypoxemia, drug effects, sleep deprivation, and sensory deprivation or overload. It is characterized by cognitive dysfunction, varying levels of consciousness, altered psychomotor activity, and a disturbed sleep/wake cycle. (Delirium is discussed in Chapter 60.)

Anxiety and depression may also occur in postoperative patients. Any patient may experience these responses as part of grieving for lost body parts or functions or for decreased independence during the recovery and rehabilitation process.

Alcohol withdrawal delirium occurs as a result of alcohol withdrawal in a postoperative patient. It is characterized by restlessness, insomnia and nightmares, irritability, and auditory or visual hallucinations. Identification and management of alcohol withdrawal delirium are discussed in Chapter 11.

NURSING MANAGEMENT NEUROLOGIC AND PSYCHOLOGIC PROBLEMS

NURSING ASSESSMENT

Assess the patient's level of consciousness, orientation, memory, and ability to follow commands. Determine the size, reactivity, and equality of the pupils. Also assess the patient's sleep/wake cycle and sensory and motor status. If the neurologic status is altered, try to determine possible causes. If the patient was mentally alert before surgery and becomes cognitively impaired postoperatively, you should suspect delirium or POCD.

NURSING DIAGNOSES

Nursing diagnoses related to neurologic or psychologic problems include, but are not limited to, the following:

- Acute confusion *related to* hypoxia, postoperative cognitive dysfunction, delirium
- Anxiety *related to* change in health status, hospital environment
- Disturbed body image *related to* loss of body part(s), function
- Disturbed sleep pattern *related to* pain, hospital environment

NURSING IMPLEMENTATION

PACU. The most common cause of postoperative agitation in the PACU is hypoxemia. As a result, focus your attention on evaluating respiratory function. Once you have ruled out hypoxemia or other known causes of postoperative delirium, sedation may be beneficial in controlling the agitation. Because the most common cause of delayed emergence is prolonged drug action, delays in awakening usually spontaneously resolve with time. If necessary, benzodiazepines and opioids may be reversed with drug antagonists.

Until the patient is awake and able to communicate effectively, be a patient advocate and maintain patient safety at all times. This includes having the side rails up, securing equipment (e.g., IV lines, artificial airways), monitoring physiologic status, and verifying the presence of identification and allergy bands.

Clinical Unit. To prevent or manage postoperative delirium or POCD, address factors that are known to contribute to the condition. Maintenance of normal physiologic function is important and includes fluid and electrolyte balance, adequate nutrition and sleep, pain management, proper bowel and bladder function, and early mobilization. To help orient the patient, use specific aids, such as clocks, calendars, and photos.

To prevent or limit psychologic problems, provide adequate support for the patient. This includes listening to and talking with the patient, offering explanations and reassurance, and encouraging the presence and assistance of the patient's caregiver(s). Evaluate the patient's behavior to distinguish a normal reaction to a stressful situation from one that is becoming abnormal or excessive. The recognition of alcohol withdrawal delirium presents a particular challenge. Document and report any unusual or disturbed behavior so that a diagnosis and treatment may be made.

PAIN AND DISCOMFORT

Etiology

Despite the availability of pain-relieving drugs and techniques, pain remains a common problem and a significant fear for

patients. Postoperative pain is caused by the interaction of a number of physiologic and psychologic factors. The skin and underlying tissues have been traumatized by the incision and retraction during surgery. In addition, there may be reflex muscle spasms around the incision. Anxiety and fear, sometimes related to the anticipation of pain, create tension and further increase muscle tone and spasm. Positioning during surgery or the use of internal devices such as an endotracheal tube or catheters may also result in pain. The effort and movement associated with deep breathing, coughing, and ambulating may aggravate pain by creating tension on the incision area.

When the internal viscera are cut, no pain is felt. However, pressure in the internal viscera elicits pain. Therefore deep visceral pain may signal a complication such as intestinal distention, bleeding, or abscess formation. Pain also increases the risk of atelectasis and impaired respiratory function.[10]

NURSING MANAGEMENT
PAIN

NURSING ASSESSMENT

The patient's self-report is the single most reliable indicator of pain. Since this is not always possible in the PACU, observe the patient for other indications of pain (e.g., restlessness, changes in vital signs, diaphoresis). Identifying the location of the pain is important. Incisional pain is to be expected, but other causes of pain, such as a full bladder, may also be present.

The American Society for Pain Management Nursing and American Society of PeriAnesthesia Nurses have developed evidence-based guidelines for the nursing management of pain throughout the perioperative experience.[11,12] In addition, The Joint Commission requires that effective pain management strategies be implemented for all patients experiencing pain.[13] (Pain is discussed in Chapter 9.)

NURSING DIAGNOSES

A nursing diagnoses for the patient experiencing pain includes, but is not limited to, the following:

- Acute pain *related to* inflammation or injury in surgical area

NURSING IMPLEMENTATION

The most effective interventions for postoperative pain management include using a variety of analgesics. IV opioids provide the most rapid relief.[14] More sustained relief may be obtained using epidural catheters, patient-controlled analgesia (PCA), or regional anesthetic blockade.

Orders for analgesic medication and other comfort measures are often written on an as-needed (PRN) basis. During the first 48 hours or longer, opioid analgesics (e.g., morphine) are required to relieve moderate to severe pain. A combination of two analgesics (e.g., an opioid and a nonsteroidal antiinflammatory drug [NSAID]) may be used to provide the lowest dose of medication and decrease side effects.[15] Nonopioid analgesics, such as NSAIDs, may be sufficient as pain decreases.

Time the administration of analgesics to ensure that they are in effect during activities that may be painful, such as walking. Although opioid analgesics are often essential for the postoperative patient's comfort, there are undesirable side effects. The most common include constipation, nausea and vomiting, respiratory and cough depression, and hypotension. Before administering any analgesic, first assess the patient's pain, including location, quality, and intensity; respiratory rate; and level of consciousness. If it is incisional pain, analgesic administration is appropriate. If it is chest or leg pain, medication may simply mask a complication (e.g., VTE). If it is gas pain, opioids can aggravate it. If the analgesic either fails to relieve the pain or makes the patient excessively lethargic or somnolent, notify the physician and request a change in the order.

Patient-controlled analgesia (PCA) and epidural analgesia are two alternative approaches for pain control. The goals of PCA are to provide immediate analgesia and to maintain a constant, steady blood level of the analgesic agent. PCA involves self-administration of predetermined doses of analgesia by the patient. The route of delivery may be IV, oral, epidural, or transdermal. The transdermal route is designed for short-term pain management and may offer advantages over the IV route (e.g., needleless, low infection risk, decreased medication errors associated with inaccurate pump function or programming).[14] Some advantages of PCA are early ambulation, better pain management than with PRN analgesia, and greater patient satisfaction. (PCA is discussed in Chapter 9.)

Epidural analgesia is the infusion of opioid analgesics through a catheter placed into the epidural space surrounding the spinal cord (see Fig. 19-6). The goal of epidural analgesia is delivery of medication directly to opiate receptors in the spinal cord. Administration methods include intermittent bolus dosing, continuous infusion, and patient-controlled epidural analgesia. This technique results in a constant circulating level and a reduced total dose of medication. The use of epidural analgesia for postoperative pain is increasing. Superior pain relief and improved functional outcomes after major surgery have been found in patients who receive epidural analgesia compared with those who receive IV opioids.[16,17]

Postoperative pain can also be managed by the infiltration of a nonopioid medication into the surgical site. A single dose of bupivacaine liposome injectable suspension (Exparel) provides pain relief with reduced opioid requirements for up to 72 hours.

The acute pain of surgery almost always requires the use of analgesics. However, nondrug approaches such as repositioning, massage, distraction, and deep breathing can enhance pain management. Complementary and alternative therapies such as music therapy, guided imagery, relaxation exercises, and aromatherapy have also been shown to be effective adjuncts in pain management.[18,19]

ALTERATIONS IN TEMPERATURE

Etiology

The patient's temperature in the postoperative period provides valuable information (Table 20-6).

Hypothermia. *Hypothermia,* a core temperature less than 96.8° F (36° C), occurs when heat loss exceeds heat production. Heat loss may occur due to skin exposure by the surgical procedure and the use of cold irrigants and unwarmed inhaled gases.[20] Although all patients are at risk for hypothermia, patients with a systolic BP less than 140 mm Hg, older patients, and female patients are at a higher risk of developing hypothermia postoperatively.[21] Long surgical procedures and prolonged anesthetic administration lead to redistribution of body heat from the core to the periphery. This places the patient at an increased risk for hypothermia.

Hypothermia can affect the patient's perception of the perioperative experience. The complications associated with hypo-

TABLE 20-6 POSTOPERATIVE TEMPERATURE CHANGES

Time After Surgery	Temperature	Possible Causes
Up to 12 hr	Hypothermia: ≤96.8°F (36°C)	Effects of anesthesia, body heat loss during surgical procedure
First 48 hr (postop days 1 and 2)	Mild elevation: ≤100.4°F (38°C)	Inflammatory response to surgical stress
	Moderate elevation: >100.4°F (38°C)	Lung congestion, dehydration
After first 48 hr (postop day 3 and later)	Elevation >100°F (37.8°C)	Infection (e.g., wound, urinary, respiratory)

thermia can include compromised immune function, bleeding, untoward cardiac events, impaired wound healing, altered drug metabolism, and postoperative pain and shivering.[22] Shivering can increase oxygen consumption, carbon dioxide production, and cardiac output, as well as significantly affect the patient's comfort level.

Fever. Fever may occur at any time during the postoperative period (see Table 20-6). Wound infection, particularly from aerobic organisms, is often accompanied by a fever that spikes in the afternoon or evening and returns to near-normal levels in the morning. The respiratory tract may be infected secondary to stasis of secretions in areas of atelectasis. The urinary tract may be infected secondary to catheterization. Superficial thrombophlebitis may occur at the IV site. VTE in the leg veins may produce a temperature elevation.

Surgical patients who receive antibiotics for a period of time are at risk for *Clostridium difficile* infections. Manifestations of *C. difficile* may include fever, diarrhea, and abdominal pain.

Intermittent high fever accompanied by shaking chills and diaphoresis suggests septicemia. This may occur at any time during the postoperative period because microorganisms may have been introduced into the bloodstream during surgery, especially in GI or genitourinary (GU) procedures. Septicemia may also occur later from a wound or urinary tract infection.

NURSING MANAGEMENT ALTERED TEMPERATURE

NURSING ASSESSMENT

Frequent assessment of the patient's temperature is important to detect patterns of hypothermia or fever. Temperature may be taken orally, temporally, or via the tympanic membrane. The same route of temperature measurement should be used while the patient is in the PACU.[21] Also assess the color and temperature of the skin. Observe the patient for early signs of inflammation and infection that may precede a fever so that any complications can be treated in a timely manner.

NURSING DIAGNOSES

Nursing diagnoses related to an altered temperature include, but are not limited to, the following:

- Hypothermia *related to* long surgical procedures, prolonged use of anesthetics
- Risk for imbalanced body temperature

NURSING IMPLEMENTATION

Passive warming measures include the use of warmed cotton blankets, socks, and reflective blankets and limiting skin exposure. *Active warming measures* involve the application of external warming devices, including forced air warmers; heated water mattresses; radiant warmers; heated, humidified oxygen; and warmed IV fluids. When using any external warming device, assess body temperature and the patient's comfort level at 15-minute intervals.[21] In addition, take care to prevent skin injuries. Oxygen therapy via nasal prongs or mask is used to treat the increased demand for oxygen caused by shivering. Shivering can be treated with opioids (e.g., meperidine [Demerol]).

Measure the patient's temperature every 4 hours for the first 24 hours postoperatively and then less frequently if no problem develops. Meticulous asepsis is required with wound and IV site care. Airway clearance is encouraged with deep breathing, coughing, and the use of the incentive spirometer. If fever develops, chest x-rays may be taken and antipyretic drugs given. Depending on the suspected cause of the fever, cultures of the wound, sputum, urine, or blood are obtained. If a bacterial infection is the source of the fever, antibiotics are started as soon as cultures have been obtained. If the fever rises above 103°F (39.4°C), body-cooling measures may be used.

GASTROINTESTINAL PROBLEMS

Etiology

Nausea and vomiting remain the most common postoperative complications. Risk factors include gender (female), history of motion sickness or previous postoperative nausea and vomiting, action of anesthetics or opioids, and duration and type of surgery.[1,21] Delayed gastric emptying and slowed peristalsis that result from handling of the bowel during abdominal surgery also contribute to nausea and vomiting, as does the resumption of oral intake too soon after surgery.

Postoperative ileus, or the temporary impairment of gastric and bowel motility after surgery, is another common problem and is an expected result of major abdominal surgery.[23] It results from the handling or reconstruction of the intestine during surgery and limited dietary intake before and after surgery. After abdominal surgery, motility in the large intestine may be reduced for 3 to 5 days, although motility in the small intestine resumes within 24 hours. Use of opioid analgesia prolongs the duration of postoperative ileus.[23] Abdominal distention and gas pains can occur as a result of decreased bowel motility, swallowed air, and the accumulation of GI secretions.

Hiccups (singultus) are intermittent spasms of the diaphragm caused by irritation of the phrenic nerve, which innervates the diaphragm. The phrenic nerve may be irritated postoperatively by gastric distention, intestinal obstruction, intraabdominal bleeding, and a subphrenic abscess. Indirect irritation of the phrenic nerve may be produced by acid-base and electrolyte imbalances. Reflex irritation may come from drinking hot or cold liquids or from the presence of a nasogastric (NG) tube. Hiccups usually last a short time and subside spontaneously.

NURSING MANAGEMENT GASTROINTESTINAL PROBLEMS

NURSING ASSESSMENT

Ask the patient about feelings of nausea. If vomiting occurs, determine the quantity, characteristics, and color of the vomitus.

Assess the abdomen for distention and the presence of bowel sounds. Because bowel sounds are frequently absent or diminished in the immediate postoperative period, auscultate all four quadrants to determine the presence, frequency, and characteristics of the sounds. The return of normal bowel motility is usually accompanied by the passage of gas or stool and the patient's ability to tolerate oral intake without complaints of nausea or vomiting.[24]

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems related to GI problems include, but are not limited to, the following:

- Nausea *related to* anesthetic agents, manipulation of abdominal contents
- Imbalanced nutrition: less than body requirements *related to* vomiting, decreased appetite, decreased peristalsis
- Risk for imbalanced fluid volume
- Risk for electrolyte imbalance
- Potential complication: hiccups

NURSING IMPLEMENTATION

Postoperative nausea and vomiting are treated with antiemetic or prokinetic drugs (see Chapter 42, Table 42-1). In the PACU, oral fluids should be given only as ordered and tolerated. IV fluids will provide hydration until the patient is able to tolerate oral fluids. Be alert to prevent aspiration if the patient vomits while still sleepy from anesthesia. Position the patient in the lateral recovery position and have suction equipment readily available at the bedside. Complementary and alternative therapy interventions for nausea and vomiting include guided imagery, music therapy, aromatherapy, distraction, and acupressure.[25]

Depending on the type of the surgery, the patient may begin oral intake as soon as the gag reflex returns. The patient who has abdominal surgery is usually allowed nothing by mouth (NPO) until the return of peristalsis. Chewing gum has been found to aid in the return of bowel motility.[26,27] When the patient is NPO, IV infusions are given to maintain fluid and electrolyte balance. An NG tube may be used to decompress the stomach to prevent nausea, vomiting, and abdominal distention. Regular oral care is essential for comfort and stimulation of salivary glands when the patient is NPO or has an NG tube. When oral intake is allowed, clear liquids are offered first and the IV infusion is continued, usually at a reduced rate. If oral intake is well tolerated, the IV infusion is discontinued, and the diet is advanced until a regular diet is tolerated.

Despite limited evidence to support early ambulation for abdominal distention, it is a standard postoperative intervention.[28] Assess the patient regularly to detect the return of peristalsis as evidenced by the passage of gas or stool. The NG tube must be clamped or the suction turned off when the abdomen is auscultated. Resumption of a normal diet after bowel sounds have returned also enhances the return of normal peristalsis.

Encourage the patient to expel gas. Gas pains, which tend to become pronounced on the second or third postoperative day, may be relieved by ambulation and frequent repositioning. Positioning the patient on the right side permits gas to rise along the transverse colon and aids its release. Bisacodyl (Dulcolax) suppositories may be ordered to stimulate colonic peristalsis and expulsion of gas and stool.

URINARY PROBLEMS

Etiology
